I think, generally given the preference. This may account for the greater extraction in most cases when potassium cyanide is used. The evidence is complicated by the fact that much of what we in the United States have used as potassium cyanide is only the sodium salt, diluted, so if the metallurgist switched one to the other in this case, there would be no apparent difference in extraction, as the sodium salt would be used in each case. It may be that cases where a difference between the extractions have been observed are those where a real comparison of the salts obtained through the potassium cyanide being the real thing. It may be that the foisting of diluted sodium cyanide on the operators in America has been the cause of a considerable financial and national loss through imperfect extractions. This in part is to be blamed on the tinkered up tariff schedule that charged a higher duty on the sodium salt, making it an object to perpetrate the fraud, not only on the Government, but on the public.

It is not likely to be continued now that the duty is removed from both, but it behooves operators everywhere to look carefully into this question, beginning the investigation with a determination of the metal radical of their salt if supposedly potassium cyanide is used, and if the sodium salt is used to try out the other salt in comparison. I believe that in a majority of cases the conclusions will agree with Mr. Butters' Divisadero results; that the potassium salt will give a greater extraction at a less cost. In his case, taking the last four years, two with one and two with the other, the sodium cyanide shows 1.85 lb. against 2.05 lb. of potassium cyanide, which, at the prices given, shows a financial advantage of 6c. per ton in direct saving, and over 3% better saving in gold.

Los Angeles, April 2.

What Is the Matter With Prospecting?

The Editor:

Sir—I have followed prospecting for a great many years; finding prospects and earning grubstakes to develop them. The fact that "there is plenty of money" to develop prospects is undoubtedly true, but those prospects must be sufficiently developed to show an amount of ore in excess of the price offered, and then the prospector must wait from one to two years for the cash. The old custom of people with money 'taking a chance' to develop a good iron-cap or other promising lode is past; we prospectors must show the 'goods' or there is no trade. The time when we could sell a reasonably fair prospect for a few hundred dollars, and then move on to find another, is gone. Now we have to find the prospect, then go and earn our own grubstake by wages, and develop our claim. Hence it takes years, where before it took months. The money available seems to be in the hands of the big mining companies, and they buy on a 'sure thing' margin. This condition of 'sure thing' buying is

caused by the mining engineers employed by the companies. Their jobs depend on their ability to pick paying properties, and they therefore turn down many otherwise good claims. There is plenty of interest, but it seems to be centred around the big concerns.

Personally I would not care to be placed on the government payroll. I would rather sell a claim once in a while. The Government might extend the service of the Geological Survey by producing reports sooner and by examining and reporting on mineral claims for prospectors, should they so desire. As a rule, prospectors are too poor to hire mining engineers, and a report from the Geological Survey would aid greatly in selling, or perhaps satisfy the prospector that the claim is no good and that therefore he need waste no more time on it. The apex law as it now stands looks good to me, though I think it well to enlarge the claims to 1500 ft. square, which would do away with a great many cross-claims, from which much litigation arises, and also provide more timber for mining. Government aid in building trails and roads would be greatly appreciated, also assay offices where assays could be procured at cost, if not free.

Of course, the 'wild-catter' is largely responsible for the falling off in prospecting, and, too, I have been told that "there are more failures in mining from mismanagement than from lack of mineral," which has a large bearing on selling prospects—perhaps larger than any other cause.

J. C. STUTZ.

Danville, Washington, February 18.

The Editor:

Sir—One of the writers on this subject says: "The nomadic prospector, with his shovel, pick, pan, and a sack of grub, on a burro, is largely of the past," and it is not worth while trying to revive him; yet an item in a Portland paper of January 21 says: "The usual winter influx of argonauts, prospectors of the good old golden days of placer mining, is scattered along the Rogue river with pick and pan, striving for a grubstake, and still looking forward to striking it rich." There are still Klondikes, Iditarods, and Chisanas to be discovered; other Tonopahs and Goldfields will be opened up; as also more High Grades and Buffalo Humps will put temporary dampers on the enthusiasm of nomadic prospectors. In the United States, notwithstanding statements to the contrary, there are still vast areas of virgin ground, immense territories practically unscratched; northern California, Oregon, southern Idaho, northern Nevada, and much of the southeastern states is still open to the search. Northern Canada, the Labrador country, and northern British Columbia are practically unknown; Siberia, China, and Tibet have never been prospected, and millions of square miles of Africa have scarcely been entered. Who is to be the pioneer in the great task of opening up these districts to exploitation and improvement but the man who takes his life in his hands,

eats as he tramps, and sleeps wherever night overtakes him as he forges deeper and deeper into the wilds?

W. S. KEITH.

Portland, Oregon, February 20.

The Editor:

Sir—I have waited patiently in this discussion to read what I consider the most potent factor in the decline of prospecting and small-scale mining, but none has hit the mark. It is not because all available area has been gone over, for many veins are to be discovered in areas already prospected; it is not because of government regulations, although no doubt these have discouraged the prospector; it is not because capital is scarce; but it is because automobiles in the minds of the mass of people are more interesting than mining stock. The man with \$100, \$200, \$500, or \$1000 who formerly would take a nip at stock, now has his all in an automobile and his savings go to keep it running. Figure the amount of money put into machines by the near wealthy or near poor, and one can readily see what an important factor this industry has become in the distribution of savings. Just as the moving-picture theatre has taken coin from the saloons, so have automobiles taken money away from mining investments. We need go no further for our answer: a man who has his house mortgaged for a machine is not going to 'take a flyer' on a mining venture—the upkeep of the machine is more important.

ALGERNON DEL MAR.

South Pasadena, California, March 10.

The Editor:

Sir—As to the prospector, he is mortal and dies. With the inevitable discovery of some new bonanza gold camp a legion of young prospectors will arise as from the earth. As to the asserted exhaustion of virgin territory containing potential bonanzas, I do not agree. In northeastern California, northwestern Nevada, and southeastern Oregon there remain 25,000 square miles of territory spotted with porphyry districts wherein may be seen today ocular proof of mineral in veins of gold, silver, lead, and copper ores; not forgetting the coal formation in Modoc county. This entire domain is truly a howling wilderness awaiting the battalions of prospectors not yet organized and drilled, but in existence and ready to enlist in the noblest occupation of earth—mining. The mining industry is at a low ebb and is constantly being discredited not only by the jackals who hang on the flanks of the business, but is continually afflicted with a fire from the rear from newspapers and magazines that tout every commercial scheme, no matter how unscrupulous. And until the public domain is fully restored to the prospector, the obstacles which constantly multiply to dishearten the remnants of the old time prospectors who have accomplished so much will operate to prevent the enlisting of younger men in the ranks of those who have sub-

dued the deserts and the mountains. I am bound to write the foregoing for the reason that they are facts not sufficiently emphasized, since the prospector as a class has no journal for his spokesman.

N. E. GUYOT.

High Grade, California, February 5.

The Editor:

Sir—I have been much interested in the discussion in the *Mining and Scientific Press* on the subject of how to encourage prospectors. I note that one of the questions which you have asked representative mining men, relates to government aid. It occurs to me that something might be done along this line in the way of broadening the reports which come out of the Geological Survey. My experience has been that one reason why prospectors, and particularly why the owners of partly developed mining properties, find it difficult to interest capital is, that they are seldom able to make a proper presentation of the facts with reference to the properties for whose development they ask money. If the Government would extend the work done through the Geological Survey to the examination of prospects and partly developed properties, including a sampling thereof, and make the results of these examinations public, mining people would have something dependable to go by, and prospectors, or the owners of partly developed mining properties, would be substantially served. I submit this suggestion as a practical one with relation to the kind of aid that might be extended by the national Government to western miners.

DONALD C. CATLIN.

New York, January 21.

The Editor:

Sir—From my own observations, I would say that the tendency is for the one-time prospector to seek work with the operating companies, rather than to go into the hills; that the large development and operating companies are more exacting in their requirements, at least as regards accuracy in the reports that are submitted to them. Lacking the earmarks of accuracy, the reports of many properties that might otherwise have commanded some attention are consigned to the waste-basket.

It appears to me that there is a greater success attendant upon sending an engineer into a field that has been somewhat exploited for the purpose of gathering all available data on the mines that have been and are being operated, and then if results are encouraging to secure option or bond on properties in that district, rather than in going into new fields where results are exceedingly problematical. This, however, eliminates the prospector to a large extent, and it may be to a certain extent the reason why old-time methods of prospecting are less in vogue.

S. F. SHAW.

Frisco, Utah, March 9.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Asbestos production of Quebec in 1913 was 136,195 tons, worth \$28.10 per ton.

Water used by 11 mines at Kalgoorlie amounted to 33,414,000 tons in December last.

Black blasting powder used in coal mines is usually made of 73 parts of Chile saltpeter (sodium nitrate), 16 parts of charcoai, and 11 parts of sulphur.

Miners sometimes open metal powder kegs with the point of a pick, causing a spark and resulting in an explosion. Partly on this account, kegs are often made of cardboard.

Leaching sand at the Oroya-Black Range mill, Western Australia, takes 134 hours for an 85-ton charge, which is percolated by 125 tons of various solution washes. The gold recovery is 85.34% at a cost of 47c. per ton, according to W. B. Chomley in the *Monthly Journal of the Chamber of Mines*.

Davison's formula, $s = \frac{200}{d}$, where s equals the r.p.m. and d the diameter of the tube in inches, still holds good for the rate of revolution of tube-mills. The same authority gave the charge of flints as $0.44n$, where n equals the internal capacity, but subsequent practice has demonstrated the advisability of filling tube-mills more than half full.

Mill capacity in the Flat River lead district, Missouri, is as follows: Federal Lead Co., 4500; St. Joseph Lead Co., and Doe Run Lead Co., now consolidated, 6200; St. Louis Smelting & Refining Co., 2500; and Desloge Consolidated Lead Co., 1800 tons per 24 hours. In 1912, according to H. A. Guess, 4,064,366 tons of crude ore was milled, yielding 218,803 tons of concentrate, containing 146,913 tons of lead, worth \$13,222,170.

Moisture and acid are foes of electric insulation and are especially active when combined in mines. According to H. H. Clark and L. C. Ilsey, of the Bureau of Mines, the average amount of free sulphuric acid in 16 different mine waters was 23.68 grains per gallon. Samples of wire, covered with different insulating compounds were treated with these waters for certain periods and showed marked decreases in the insulation resistances. The rubber insulation stood better than other preparations.

A simple method of raising the boom on a revolving steam-shovel is as follows, according to the *Excavating Engineer*. Set the dipper firmly against a block on the ground diagonally forward from under

the shipper shaft. Lock thrusting gears with a bar or wedge. Propel forward slowly, thus raising the boom. This is much safer and much more accurate than using the boom engines. The boom may be lowered in the same manner.

Standard silver or gold is not of uniform composition, but its base metal content is controlled by local regulation. The American standard for both gold and silver admits of an addition of 10% of other metals. Standard gold carries 1% silver and 9% copper, and standard silver 10% copper. British standard gold contains 22 parts of gold per 24, which is locally designated 22 carat. With standard silver the carat proportions are also used in calculating base content, although the term 'carat' is not used in designating the silver fineness. Standard silver contains 22.2 parts of silver and 1.8 parts of base. Bullion is often sold in England and the colonies at so much per ounce standard gold, the price including the proportion of silver found in standard gold. Any additional silver content is paid for at the ruling market price of the metal.

A useful type of apparatus for cleaning-up mill accumulations and for amalgamating the gold in cyanide slag is the berden pan. The standard size is 5 ft. in diameter. The pan consists of a revolving circular trough, in one casting, driven by a shaft set at an angle of about 45°, which is fixed through the centre of the trough and terminates in a footstep bearing. The pan runs at a speed of from 12 to 15 r.p.m. by bevel gearing, the pinion being loose on the driving shaft so that the pan can be stopped in disengaging the gears by means of a suitable strike. The grinding is done by means of a cast iron ball, which revolves in a pool of mercury in the concavity of the trough and which weighs about 120 lb. The material to be amalgamated is thus brought in close contact with the 'quick.' A continuous stream of water may be added to the pan so that the fine material can escape as soon as ground, to be subsequently caught in a settler; or the pan may be run with intermittent charges. The former method is preferred by some millmen, as it allows for the thorough cleansing of the mercury by stopping all feed to the pan for a few hours previous to cleaning-up, while others are certain that a better recovery is made by the intermittent system. The ball used for grinding is particularly well adapted for the purpose, and its use results in a minimum of wear. When anything in the nature of a drag or shoe is used the iron invariably found in mill accumulations is held by it. This results in scouring and severe wear of the pan body. Liners are unsuitable for this type of pan on account of the amalgam working through and lodging between the liner and the pan, although they have been used without much bother from this source. The pan body is in the form of one simple casting and even with continuous use will last for a number of years if a ball is used for grinding.

Special Correspondence

PLATTEVILLE, WISCONSIN

CONDITIONS AND PRICES IN MARCH.—DISTRICT PRODUCTION.—
MINES CONTRIBUTING TO THE OUTPUT.—ORE BUYERS.—
PRICES FOR CERTAIN GRADES.

Producers of zinc ore in this region had a distressing and discouraging time in March; yet in spite of all the drawbacks, it proved the best month so far of this year. Inclement weather prevailed most of the month, wagon roads were for the most part impassable and outlying mines were almost entirely isolated and market conditions were at a dead standstill, metal ruling for the month at \$5.15 per cwt., East St. Louis quotations, with scarcely any deviation from this figure at any time. Zinc ore showed a wide latitude between high and low-grade ores, ranging from \$36 to \$40 per ton, for standard grades. Low-grade ore was in good demand, and some competition led to prices being paid of from \$1 to \$2 per ton above average base, on low and medium grade zinc ore production.

While soft ground militated against the free movement of drilling machines and material to new mining sites, some removed by a considerable distance from established roads, there was nevertheless a good increase of action along these lines during the period. Scores of Keystone drills were in operation, while machinery and building material was provided for a number of new power, mining, and concentrating equipments. Ore production showed strong gains, and shipments were above the reports issued for February. The following figures include deliveries made on March 28. Lead ore shipments were almost too insignificant to deserve mention, the demand and prices offered furnishing no incentive for producers to 'let go.' Production of iron pyrite held up well, but deliveries were lighter, due to bad roads. At the close of the month, fully 5000 tons of zinc ore carried over.

| Districts. | Zinc lb. | Lead lb. | Pyrite lb. |
|--------------------------|-------------|-------------|---------------|
| Benton | 4,310,000 | | 2,658,000 |
| Galena | 4,292,000 | 79,600 | |
| Cuba | 3,094,000 | | 991,840 |
| Platteville | 2,396,000 | | |
| Livingston | 2,280,000 | | |
| Hazel Green | 1,970,000 | 50,000 | |
| Linden | 1,736,000 | 119,560 | 492,500 |
| Shullsburg | 1,704,000 | | |
| Harker | 1,372,000 | | |
| Montfort | 226,000 | 64,000 | |
| Highland | 60,000 | | |
| Mineral Point | 20,000 | | |
| New Jersey Zinc Co. | 2,806,600 | | |
| Total | 26,342,600 | 313,160 | 4,142,340 |

The mines responsible for this production are given by districts, namely: Benton—Frontier, Fox, Fields, Indian Mound, Wilkinson, and Martin; Galena—Black-Jack, Vinegar Hill, Northwestern, Federal and Great Western Lead Mfg. Co. (new); Cuba—Masbruch mine and National Sep. Co.; Platteville—East End mine and Empire roasters; Livingston—Coker, Ellsworth, and Rundell; Hazel Green—Kennett and Cleveland; Linden—Ross Bros., Glanville, Saxe-Pollard, Optimos No. 1 and 2, and Linden Sep. Co.; Shullsburg—Winskill mine only; Harker—Peacock, B. M. & B. Mining Co., Lucky Six; Montfort—O. O. David, Dodgeville, Lucky Five, Mineral Point local, and Section Four out of Highland.

Among buying concerns the tonnage was distributed as follows: Mineral Point Zinc Co., 4712 tons; National Separating

Co., Cuba, 2265 tons; Grasselli Chemical Co., Cleveland, 1279 tons; Empire roasters, 819 tons; Linden Zinc Separating Co., 652 tons; M. & H. Zinc Co., LaSalle, Illinois; 667 tons; Illinois Zinc Co., Peru, Illinois, 643 tons, and American Zinc Co., 352 tons.

The gross production of concentrates aggregated 20,000,000 lb., and net refined ores from separating plants and concentrates direct to smelter, 13,000,000 lb. More attention is being given to ore separation and the shipments of high-grade separator finished product is gradually increasing all over the field, and no doubt will eventually be confined to shipments of high-grade ore out of the field to smelter direct altogether.

Prices paid for the different grades submitted by one of the most prominent buyers in the field show the following figures: for 30% zinc content, the average low-grade ore of this field, \$14.50; 35%, \$17; 40%, \$20; 45%, \$23 to \$24; 50%, \$28 to \$30; 55%, \$32 to \$34; and 60%, \$37 to \$40 per ton. The Linden Ore Separating Co. produced 62% ore and carried off field honors with the top price of \$42 per ton.

KALGOORLIE, WESTERN AUSTRALIA

WAGE DEMANDS.—ASSOCIATED NORTHERN BLOCKS' AFFAIRS.—
DEVELOPMENT IN THE CHAFFERS.—BULLFINCH RETURNS.—
GREAT BOULDER COMPANY'S OPTION IN VICTORIA.

The miners' unions of Bullfinch, Golden Ridge, and Leonora have all applied for a higher schedule of rates on the expiring of the current agreement, which is about to fall due. With regard to Bullfinch, the Chamber of Mines offered an increase of 12c. per shift for hand labor in raises, and 12c. per shift extra for all surface work. The miners turned down this offer, and all three cases will now go to the Arbitration Court. The Golden Ridge case appears foolish, as there is only one mine concerned, and it is nearly worked out, and will be closed down and abandoned in the course of the current year. For over a year the Company has been looking

ASSOCIATED NORTHERN MILL, KALGOORLIE, WHICH HAS FINISHED A 10 YEARS' RUN, AND IS NOW BEING DISMANTLED.

for a new mine, and at present has an option on the Idaho, east of the Hannan's Star, Kalgoorlie; but this option is shortly to be abandoned, as the lode is too patchy for profitable operation by this Company.

The Associated Northern Blocks has closed down both the Iron Duke mill at Boulder, and the Victorious mill at Ora Banda, and will earn no revenue until the sulphide plant on the latter is installed. The Iron Duke mill has closed down permanently, and the public has been notified that no more ore will be treated for prospectors in future. In the meantime development is being pushed on in the Victorious at No. 6 and the shaft is well on its way to No. 7 level. The bricks

for the foundations of the furnaces are being made on the mine, and it is probable that the Merton furnaces and Krupp ball-mills from the Kalgoorlie property will be removed to Ora Banda. The ore-shoot on the No. 6 level of the Victorious appears to have split into three parts, and shows 40 ft. of ore assaying \$14.76 per ton, then 77 ft. of waste, followed by 30 ft. assaying \$19.20 per ton. Another blank of 43 ft. is followed by 20 ft. of ore assaying \$10.56, and 50 ft. assaying \$5.04 per ton. The drift is 6 ft. wide in the hanging wall of the lode, and there may be better gold content in the foot-wall, as at 70 to 100 ft., where it is barren in the drift, the foot-wall side assays \$10.08 per ton. The mine may therefore eventually develop satisfactorily.

The management of the Chaffers is still continuing development at No. 15 and 17 levels. At the former, the main west cross-cut cut No. 1 lode at 66 ft., where it was 6 ft. wide, assaying \$6.18 per ton. At 117 ft. No. 2 lode was met with, 6 ft. wide, assaying \$4.46 per ton; at 367 ft. No. 3 lode, 10 ft. wide, assaying \$6.12 per ton, and at 503 ft. No. 4 lode, 6 ft. wide, assaying \$6.72 per ton. At No. 17 level the west cross-cut cut No. 1 lode at 176 ft., where it is 10 ft. wide, assaying \$9.48 per ton, and No. 2 lode at 207 ft., where it is 5 ft. wide, assaying \$6.72 per ton. No development has been done on these lodes so far. The new treatment plant, consisting of rock-crushers, furnaces, agitation vats, filter-presses, etc., have been ordered from the West Australian Machinery Co., together with a 400-hp. National gas-engine and generator, and four No. 8 Krupp ball-mills have been ordered from Germany. The plant is not expected to be ready for six to eight months, but in the meantime the lodes at No. 15 and 17 levels will be opened, and both levels connected with No. 16. A large fan is used for ventilation purposes, otherwise it would be impossible to drive the levels so far from the shaft with no natural ventilation.

The return of the Bullfinch for January fell to \$8.80, and the profit to \$4.12 per ton against \$13.14 and \$8.62 per ton for the previous ten months since the mill started. As the rich ore is practically exhausted, returns in future will be normal and profits probably will not exceed \$24,000 per month. The creep in the mine is not likely to affect returns at present, but should rain fall, a further subsidence may be looked for. The shaft is quite safe, as the northern lode series is 450 ft. on one side, and the southern 300 ft. on the other side. A. L. Hay, the manager, is confident of the future of the mine.

Richard Hamilton, of the Great Boulder Proprietary, in an interview regarding the Company's acquisition of the Magdala-Moonlight group of mines at Stawell, in Victoria, stated that he had taken an option of 6 to 12 months, and intended testing the lode by diamond-drilling. If satisfactory, he would install a sulphide plant similar to the Great Boulder plant, and capable of treating 15,000 tons per month and of giving employment to 600 men. The probable reserve of sulphide ore in the mine was 100,000 tons, worth \$7 to \$8 per ton.

Gold returns from Western Australia in January 1914 were \$2,379,200, and from the principal mines as follows:

| Name. | Tonnage. | Value. | Profit. | Dividend. |
|--------------------------|----------|-----------|-----------|-----------|
| Great Boulder | 17,017 | \$236,650 | \$130,000 | |
| Ivanhoe | 20,238 | 165,600 | 50,000 | \$175,000 |
| Kalgoorli | 10,845 | 107,000 | 46,200 | 120,000 |
| Bullfinch | 6,316 | 57,900 | 26,800 | |

LONDON

INSTITUTION OF MINING AND METALLURGY AFFAIRS.—ROYAL SCHOOL OF MINES.—RUSSIAN MINING CORPORATION CONCESSIONS.

The annual general meeting of the Institution of Mining and Metallurgy held recently was a great success in many ways. The council's report for the year 1913 was presented, and it contained much matter for congratulation. I have already referred to the acquisition by the Institution of a house for itself. The financial position has been greatly improved by gifts of £10,000 from the Wernher estate, and by subscriptions of £3879 from 544 members toward the twenty-first anniversary fund. An appeal is now being made for a further £3000 toward this fund, in order that all indebtedness in connection with the new home may be discharged. The petition for a Royal Charter is now before the Privy Council. The Institution has a serious source of anxiety, owing to the proposals of the British Government authorities on education to amalgamate the Imperial College of Science and Technology, of which the Royal School of Mines forms a part, with the proposed glorified University of London. The Institution shares the feelings of those interested in special advanced technical training against any affiliation with a general educational university. The idea of an independent technical college, untrammelled with connections with classes on Hebrew, music, and surgery, is apparently too revolutionary for the powers that be, who go by precedent and custom more than by unbiased judgment on each case on its merits. Sir Thomas Holland, lately of the Indian Geological Survey, and now professor of geology at Manchester, has pointed out that the constitution of the older universities is not due to the ingenious design of intellectually capable men, but merely the legacy of a gouty past. Everybody connected with science intends to strenuously, but courteously, resist any proposal of the Government to place the Imperial College under the domination of unsympathetic educationalists. Let us hope that the Government will not propose to use the army for enforcing the proposed amendment of the law and constitution. On leaving the presidential chair, Bedford McNeill received unusually kind treatment at the hands of his friends and colleagues. By his continuous attention to the business of the Institution, his invariable suavity and kindness, his erudition, and his ability as a speaker and presiding officer, Mr. McNeill made himself a tremendous success, greatly to the benefit of the Institution. On his retiring, F. H. Hatch took the presidential chair. His inaugural address touched on the advantages accruing from the association of geologists

with mining operations, and also on the history of the development of the theory of ore deposits.

A few weeks ago I gave some particulars of the Russo-Asiatic Corporation, which has acquired a huge ore deposit, the Ridder, in the Altai district of western Siberia. This property formed part of the Thurn and Taxis concessions; but was acquired direct from the Russian Government, on the prince abandoning this part of the concession. The Russian Mining Corporation, controlled by F. W. Baker and Lord Harris, and responsible for the flotation of the Lena Gold-fields, has more recently acquired the remaining part of the concession from the prince himself. The property contains many thousands of square miles and is divided into two parts by the Ridder. The northern part is the Zminogorsk and the southern the Zeranovsk. During the winter, communication is maintained with the Trans-Siberian railway at Novo-Nikolaevsk by means of sleighs, and the journey from Zminogorsk takes seven days. During the summer, steamers ply on the Irtysh river, from Omsk to all the concessions. A new line, called the Altai railway, is in course of construction from Novo-Nikolaevsk and Barnaul to Semipalatinsk. It will pass within 75 miles from the Zminogorsk concession. The Kalchugina coal mines are on this route, and the railway will greatly facilitate the delivery of coal and coke to the mines. Water-power suitable for the generation of electric current is available at several places. One installation of 1500 hp. has already been erected in the Zeranovsk concession, but has been allowed to get into poor condition. Details of the concessions will be found on page 651 of this issue.

NEW YORK

COPPER SITUATION.—ANACONDA AND AMALGAMATED COPPER COMPANIES.—UNITED STATES SMELTING, REFINING & MINING CO.—UTAH CONSOLIDATED.—MIAMI.—BUTTE MINES.—STEWART'S TROUBLES.

Following its usual contradictory tendency, the market in coppers slumped immediately upon the appearance of a favorable monthly report of the Copper Producers' Association as given in this journal last week. Undoubtedly the weakness which developed was due to the fact that production for the month broke all previous records, the previous high mark for production having been made in August 1912, when total output was 145,628,521 lb. Since the first of the year, domestic deliveries have been abnormally light, in fact, including December last, the average for four months is only about 41,500,000 lb., hardly more than 50% of normal domestic consumption. This fact, taken in connection with the record shipments abroad and the somewhat discouraging business outlook at home, has not made for confidence in the stability of metal prices. The exports of copper metal have come in for the usual amount of criticism, and, despite assertions that European buyers are clamoring for early deliveries, users of metal on this side are outspoken in their belief that large amounts of copper are being held speculatively on the other side. Apparently the feeling is growing that there is more manipulation in copper than is healthy. This feeling is, in all probability, due more to the fact that the power to manipulate exists, rather than to any actual flagrant examples that can be pointed out. Another element that has never received as much consideration as it deserves from the consumer, though the producers seem to have grasped it to better advantage, is the growing appetite which the world has for copper. Production must be larger if it is to keep up with the demand, and in tracing the ascending line across the chart, temporary slumps can be disregarded. Economically speaking, it is a good thing that there is a concentrated strength behind the copper situation that can prevent temporary demoralization, and an unnecessary waste of a great natural resource.

Considerable interest attaches to the forthcoming reports

of the Anaconda and Amalgamated companies. The former had some extraordinary expenses during the past year, and production was about 20,000,000 lb. less than in 1912. Costs have increased unavoidably, in higher wages and in necessary new construction; while, on the other hand, it will probably be shown that the average price of copper sold was slightly below that received in the preceding year. It will not be a matter of surprise, therefore, if the annual report of the Anaconda should show a deficit. Amalgamated's dividend disbursements approximate the amount which it receives from Anaconda; but as both companies have substantial surplus accounts, and as Amalgamated has some other sources of income, no great importance will be attached to the showing beyond its indication as to future copper costs. It is to be recognized that Amalgamated's costs can be kept down only by increased expenditure, which is a Hibernian way of putting it, but electric haulage and the many other items of new construction and reconstruction that are chargeable to capital account are, in final analysis, additions to copper costs. It is estimated that a showing of 10% for Anaconda will be creditable for the past year.

The United States Smelting, Refining & Mining Co. makes an exceedingly good showing in its report for 1913, when it is considered that the Company now derives almost half of its revenue from its silver properties, and only about 20% from its copper mines, especially as its silver production comes from the Real del Monte and neighboring properties at Pachuca. One of the most interesting features of the report is that which refers to its efforts to acquire new properties. During 1913 there were 614 properties submitted, out of which three were purchased and three taken under option, of which options one had been allowed to lapse at the close of the year covered by the report. Commenting upon the small percentage of properties that could stand the test of examination, the *Boston News Bureau* says editorially: "It is, of course, true that mining engineers have been proved not infallible. Some of the largest contributors, present and assured, to the copper outputs of the Southwest and South America were first rejected on expert advice and long hawked about. But most of these instances, it is also to be observed, were of the low-grade 'manufacturing' type, involving not only fine calculation, but a great deal of pioneering courage and also of subsequent ingenuity in devising and adjusting. This sort of industrial mining is a very recently developed art." It is to be added to the comment of the *News Bureau* that in many of the instances mentioned the low-grade properties alluded to were obliged to wait until the present processes were developed and perfected to that point which made possible the profitable extraction of ores, which theretofore could have been handled only at great loss. In these cases the engineers who have turned down camps, which afterward developed into great profit earners, have been absolutely right all the time. Perhaps there would not be so many various things 'the matter with prospecting' if the present-day prospector could feel it incumbent upon him to prove something more than the mere existence of metals in ores, and could realize that minerals could exist and yet at the end of a year's operation would show in the balance-sheet rather as a liability than an asset.

The report of the Utah Consolidated shows earnings equivalent to \$2.12 per share, a greater profit than has been earned at any time during the past five years.

Miami failed to earn its dividend in 1913, so that in order to make the distribution to shareholders, the existing surplus was drawn upon to the extent of \$186,592. Miami's copper costs were 10.686c. per pound, which must be cut down somewhat if the property is to keep place among the porphyries. Production was 33,134,334 lb., which was sold for an average price of 15.24c. per pound.

The Davis-Daly company is to levy an assessment and become one of the deep-level properties of Butte. The smaller Butte mines seem to have a hard time to get to a satisfac-

tory producing basis. Tuolumne, Pilot-Butte, Butte-Ballaklava, and Davis-Daly have each been struggling for some years without bringing much but anxiety to the outside shareholders. Butte, on the whole, has evidently come back as a mining camp, and outside operations are more numerous than for some years past. It would be a great source of gratification in the East if there could be made some genuine spectacular successes, such as North Butte or some of the earlier mines of the camp, to bring back the attention of the public to mining possibilities. The present mining market of the East, except for some investment buying in the porphyries, and the regular grind of trading in Amalgamated, is not worth mentioning.

The troubles of the Stewart Mining Co. seem inclined to multiply. The payment of a dividend declared to be paid April 25 has been enjoined. Apparently it is a Heinze fight, and, as usual, shrouded in much entanglement arising from certain loans made by the Company to Heinze, upon which action was to be taken by the present board. The election of the present directors, who are insisting upon the payment of a dividend, is attacked as illegal, the conclusion being that the real question at issue is the disposition of the Company's earnings, by way of loans or by way of dividends.

DULUTH, MINNESOTA

WORK BEING DONE BY THE STEEL CORPORATION IN THE DISTRICT.

—REVOLVING SHOVELS FOR CLEANING-UP ORE AT THE MINES.

—THE CUYUNA RANGE.

The twelfth annual report of the United States Steel Corporation for 1913 has recently been issued and shows that its iron ore production from the Mesabi range was 21,634,206 tons, compared with 20,001,953 tons in 1912. Capital expenditure was made at the iron ore properties of the range for an additional pumping engine at the Trout Lake concentrating plant at Coleraine; a concrete-mixing plant at Hibbing; a revolving shovel at the Genoa mine; a change-house, capacity for 150 men, at the Spruce mine; a general superintendent's residence for the Virginia district; and equipment for underground operations in the following mines: Judd, Duncan, Philbin, Graham shafts No. 1 and 2, and Sullivan. During the year a new steel ore-dock was under construction at Duluth with 384 pockets, and a drying plant was installed at the Whiteside mine. At the Hull-Rust mine, pumping and lighting equipment was installed; and at the Fayal mine the engine and boiler house was enlarged and other equipment installed. Construction work on the new steel plant at Duluth, and the connecting railroad to serve the same, proceeded during the year, \$5,912,027 being spent. It is expected that this plant will be completed for operation in the spring of 1915. The plant will comprise two blast-furnaces, 10 open-hearth furnaces, one 40-in. blooming mill, one combination 12-in. and 18-in. rail and shape mill, one combination 16, 12, and 8-in. merchant mill, and a by-product coke plant of 90 ovens, together with the necessary complement of auxiliary departments, such as power-plants, pumping stations, machine and other shops. There has been laid out, adjacent to the plant, a subdivision, on which work has been commenced in building the first allotment of 170 houses for use by employees. The total expenditure to the end of 1913, for acquirement of the land, site of the steel plant and subdivision, construction of plant, development of the subdivision, and building of the railroad, is \$13,445,648. Work was commenced during the year on a cement plant situated adjacent to the new steel plant. This plant is being constructed by the Universal Cement Co., a subsidiary Company, and will have a capacity of 1,400,000 bbl. per year. It will utilize blast-furnace slag in the manufacture of the cement, and will probably be completed for operation in 1915.

An interesting feature of the work being done in the pit at the Genoa mine is the use of a Marion revolving steam-

shovel for loading ore, which is hauled to the pocket at the shaft in standard cars by locomotives, dumped, and hoisted to the surface by skips, and dumped on the stockpile. The work is carried on at a depth in the pit which will not permit of its being hauled out by locomotives. The revolving shovel is useful in this connection, as it works ahead in the corners, swings around, and deposits the ore in the car behind. The locomotive also hauls ore from the 'scrams,' which are places worked by underground methods around the edge of the pit. These places are the thin parts of the orebody which were not uncovered by the stripping operations, and the ore is mined very cheaply by this method, contracts for this sort of work having been let at different mines on the range for as low as 20c. per ton delivered on cars in the pit. The tendency, some years ago, was to use the heaviest shovels obtainable for all classes of work; but at present lighter shovels are being used for cleaning-up work; that is, removing the last cut from the surface of the ore. The success attending the use of this revolving shovel will probably result in their more general adoption, especially for the class of work in which it is now engaged, and probably also for cleaning-up, where a shallow cut necessitates much delay. The idle time of the large shovels is expensive, and their unwieldiness makes them particularly unsuited for the work. The heavy shovels are at a disadvantage on a deposit whose surface has pot-holes. The revolving shovels should be able to clean-up completely as they go along and eliminate entirely the use of teams and scrapers in final cleaning.

The Oliver Iron Mining Co. has changed its plan of attack for the orebody under Carson lake, near Hibbing, and will not pump the lake out as first proposed. Stripping from one of the adjoining mines is being dumped in the lake, and the water displaced is forced out into the drainage ditch. In this way they are killing two birds with one stone, as the problem of securing suitable dumping ground is a serious one in many instances. The underground operations, of course, will require more pumping by this method.

The Madrid mine is to be operated by the Eureka Ore Co., recently incorporated, and the balance of the ore removed as soon as possible. This mine is under the city of Virginia. The caves made by the mining operations are to be filled with stripping from an adjoining property as soon as possible so as to restore the surface to its original condition.

Developments are promising on the Cuyuna range. Many drills are at work and results are said to be showing up new orebodies in widely separated localities. The Pennington mine at Ironton and the Thompson mine at Crosby have shovels at work, and will ship ore from their pits this year. The Thompson mine was worked last year as an underground proposition. A steam-shovel is working at the Rowe pit mine at Riverton, and preparations are being made for resuming work with the hydraulic plant as soon as weather conditions permit. The Adams mine, at Oreland, has about 1500 tons of ore stocked and is pumping about 250 gal. of water per minute. The Barrowa mine of the M. A. Hanna Co., at Barrows, is hoisting about 200 tons per day and has a stockpile of about 20,000 tons. The Wilcox mine near Brainerd is to operate its pumps and compressors by electric power. The hoist and some of the pumps are to be steam driven. The new 1200-gal. pump for the Rogers Brown Ore Co.'s Armour No. 2 mine will also be electrically driven. Both the Armour No. 2 and the Kennedy mines of this Company now use electric power for surface and underground haulage.

Several of the larger independent companies operating on the Mesabi Range are now acquiring interests on the Cuyuna Range and are taking steps toward developing their interests.

Steps have been taken by the engineers of Virginia and vicinity to organize an engineer's society which will probably extend an invitation to the engineers of the range to join.

General Mining News

ARIZONA

GILA COUNTY

(Special Correspondence.)—During March, 10,330 ft. of development at the Inspiration again surpassed all previous records, but, unlike most other records in underground operation, this one was accomplished without noticeably increasing the underground payroll. Since the greater proportion of the work in this mine consists of driving the sub-level drifts and the incline raises connecting these drifts, it is possible to work a large number of faces, and, the method employed being such as practically to eliminate any handling whatever of the broken ground, the conditions are very favorable for making excellent advances. The haulage drift on the 600-ft. level is now within 200 ft. of connection, and is expected to be holed through about April 20.

At the test mill the 12-compartment flotation machine is now nearly ready for operation, and the 6 by 20-ft. tube-mill will be installed as soon as it is received. An interesting test is to be made between this mill and the Hardinge mill, as both are to be run on identical feeds and under similar conditions, to obtain a result that will be an impartial test of the two types of mills as fine grinders. This test will be exhaustive and of interest to the metallurgical world.

Machinery for the hoist and compressor plant will begin to arrive on about April 20. Among the shipments recently made were 18 cars (328 tons) of Nordberg hoisting equipment and auxiliaries, and 6 cars of compressor machinery of Ingersoll-Rand manufacture.

Several men have been engaged for the past week making the necessary excavations for installation of a 150-ton set of Fairbanks railroad track scales. These scales will be placed near the rock-crushing plant. The scales are built in four parts, having a total length of 50 ft., and are equipped with automatic registering beam. Foundations for the reverberatory furnaces are soon to be started at the smelter site.

furnaces, which will be 120 ft. long and 20 ft. wide, are to rest on slag bases. The slag will be obtained at the Old Dominion smelter at Globe, whence it will be brought in slag pots, and while still molten will be poured into the foundation pits so that upon solidifying it will adapt itself to all the minor irregularities and form a massive block of material universally regarded by smeltermen as the most desirable for this class of work. The American Bridge Co. has sub-let its contract for the smelter plant to the Oscar Daniels Co. of New York City. Axel Peterson will be in charge of the erection work for this firm. The Miami underground work covered 3656 ft. in March, and the ore milled was 111,098 tons. The Miami company has started to remodel the mill so that it will have a daily capacity of 4000 tons, with higher extraction than at present.

Miami, April 9.

MARICOPA COUNTY

(Special Correspondence.)—The Copper Belt Mining Co. owns 300 acres of property near the Monte Cristo silver mines, near Wickenburg. A 15-hp. gasoline engine and hoist have been installed, while a head-frame and machine-drills are to be added. A shipment of ore to the El Paso smelter averaged \$21 per ton in copper, gold, and silver. A reverberatory furnace will probably be erected.

Phoenix, April 2.

MOHAVE COUNTY

(Special Correspondence.)—The main shaft of the Southwestern Mining Co. is to be sunk another 200 ft., and a large tonnage of copper ore is expected to be found. Mining is being done in sulphide ore at present.

Coppeville, April 2.

During March the Tom Reed mine yielded gold worth \$105,000. The winze from the 900 to the 1100-ft. level is nearly through, and is in high-grade ore. The Gold Road mill is treating 300 tons of ore per day, yielding about \$24,000 per week. A good orebody is being opened at 1000 ft. in the Tennessee mine at Chloride. A 40-hp. engine has been installed at the Gold Reed mine for the air-compressor. The Midnight mine has been examined by officials of the American Smelting & Refining Co. At the Telluride property, the shaft is down 200 ft., and good ore is being developed. A 6-drill compressor is to be installed. The mine adjoins the Tom Reed on the south, and is managed by J. E. Rose.

CALIFORNIA

AMADOR COUNTY

There is said to be a good deal of activity in the Plymouth district, apart from that at the Plymouth Consolidated. The old Rhetta claims have been acquired by Thomas Lane and associates, and work is to be started. The Myers ranch has been optioned to these people also. Good ore has been opened in the Alpine.

CALAVERAS COUNTY

Miners in this county are prospecting for gravel channels. At the Emerson mine, on Stockton hill, a good deal of driving has been done to connect with an old shaft. The old Magee and Megaw adit is in 2000 ft., and small quantities of 'pay' gravel have been opened. The Stockton Ridge Consolidated gravel claim is being actively worked under Stephen Hughes. Dredging people are sampling ground in Chili gulch.

ELDORADO COUNTY

In the *Mountain Democrat* of April 11 and 18, the Mother Lode in this county is described in an interesting manner by Harold Macdonald.

NEVADA COUNTY

Very rich ore is being extracted from the Pennsylvania mine at Grass Valley.

SHASTA COUNTY

(Special Correspondence.)—Ore will be sent to the Mammoth smelter early in May from the Shasta Belmont mine,

PART OF SHASTA COUNTY.

which is developing satisfactorily. Considerable prospecting is going on in the vicinity of Heroult and Copper City, and several encouraging discoveries have been reported recently. The ore contains a good deal of zinc in addition to copper, also silver and gold. Good progress is being made with the

erection of buildings at the camp of the Mountain Copper Co. near Minnesota station, a short distance from Keswick. The site for the concentrating plant is being graded, and it is expected to have the 250-ton plant in commission before the end of summer. It is estimated that shipments of high-grade ore from the Iron Mountain mine to the smelter at Bay Point averages about 12,000 tons per month.

Redding, April 6.

SIERRA COUNTY

Work has been resumed at the Little Bear Creek mine above Alleghany, and the Balsam Flat mines, on Lafayette ridge. At the former the 3-stamp mill may be replaced by 10 stamps. J. W. Evans is superintendent. At the latter mine, development is to include driving under a gravel deposit.

COLORADO

It is expected that by May 1 there will be 29 mining counties of the state, with a total membership of 5000, that will have joined the Colorado Metal Mining Association, while by the end of the year there will be 12,000 members. The aims of the society are to benefit the mining industry generally.

CLEAR CREEK COUNTY

(Special Correspondence.)—The ore production of the district for March 1914 was 27% above that of 1913, \$32,000 having been paid out at the local sampler. Four to five feet of \$30 gold-silver-lead ore has been opened by the adit on the Avalanche vein at Freeland. Ore returning a settlement of 250 oz. silver and 40% lead was opened in the Young America mine. Three cars of \$35 to \$55 gold-silver ore are being shipped weekly from the New Era at Freeland.

Idaho Springs, April 6.

GILPIN COUNTY

At the Carr mine, lessees are meeting with good results, and shipments down to 800 ft. have yielded good returns in gold, silver, and copper. The shaft has been repaired to below 1100 ft. The Bates Leasing Co., of Chase gulch, Black Hawk, is making fair shipments. Ten tons from the 400-ft. level returned 1.69 oz. gold, 17.2 oz. silver, and 2.2% copper. Three lots from the Pittsburg yielded the following: 3.22, 4.45, 11.5 oz. gold; 4.8, 5.75, 10.5 oz silver; and 6.75, 6.75, 19.3% copper respectively.

MONTROSE COUNTY

There is considerable activity in the carnotite mining district in spite of bad weather. There are reported to be 40 cars of ore between Placerville in San Miguel county and Paradox in Montrose county.

PARK COUNTY

A number of claims have been located in the new district containing rich uranium ores, near Hartsell, about 45 miles from Cripple Creek.

SAN MIGUEL COUNTY

The Tomboy mill treated 12,515 tons of ore in March, yielding bullion and concentrate worth \$81,500, with a profit of \$26,000.

TRIFUR COUNTY (CRIPPLE CREEK)

The cross-cut at 1750 ft. in the Portland has been driven 40 ft., and has opened 6 ft. of good ore. Eleven feet of rich ore is being opened at 350 ft. in the El Oro, and a car of ore per day is being shipped. Lessees at 600 ft. in the Gold Dollar are driving on 4 ft. of good ore.

IDAHO

The proposal to abolish the federal assay offices in the Western states is meeting with vigorous opposition from the mining interests, and the Boise chapter of the Idaho Mining Association is endeavoring to get Congress to block the move to close the Boise office. Net earnings of this office during the past nine months were over \$31,000.

SHOSHONE COUNTY

Shipments of ore and concentrate from 15 mines in the

Coeur d'Alene district in March totaled approximately 40,880 tons, containing lead, silver, zinc, and copper. A large tonnage of zinc ore has been developed in the Interstate-Callahan mine on East Nine Mile. An ore-shoot has been opened for 1100 ft. Seventy men are employed in the mine. Developments in the Hypotheek, down to 700 ft. are highly encouraging. The Snowstorm Mining Co., which recently purchased the Missoula copper mine for \$600,000, has 15 men employed at present. A writer in *The Wallace Miner* reports that the Butte Creek district at Murray contains promising mines. The new mill for the National copper mine at Mullan is working.

MICHIGAN

HOUGHTON COUNTY

Reports covering operations of several of the copper companies during 1913 are as follows:

On March 9, 1914, the Allouez Mining Co. had 339 men employed against 308 in July 1913, when the strike started. Early last year No. 2 mill started with four Hardinge mills, which are doing good work. 'Rock' stamped was 236,663 tons, compared with 333,618 tons in 1912. The copper output was 4,091,129 lb., of which 3,819,324 lb. was sold for \$598,558. The profit was \$155,728, and balance of assets are \$249,292. The total cost per pound was 12.09 cents.

On March 9, 1914, the Centennial Copper Co. was employing 164 men compared with 118 at the time of the strike in July 1913. During the past year the stamps crushed 85,443 tons of 'rock.' No. 2 mill with four Hardinge mills were started early in the year. The output of copper was 1,612,262 lb., of which 1,355,496 lb. was sold for \$208,174. The net profit was \$31,397, and surplus is \$27,847. The cost of production was 13.38c. per pound of refined copper.

Results of the Isle Royale Copper Co. were as follows: There was 314,679 tons of 'rock' stamped, yielding 4,158,548 lb. of copper, of which 3,870,974 lb. was sold at 15.29c. per pound. Receipts were \$591,933, and the year's work left a deficit of \$128,313. The previous surplus was \$557,743, but this was reduced to \$175,441. The cost per pound of copper was 18.81c. Development during the first six months of the year, and prior to the strike, covered 11,972 feet.

The Quincy Mining Co. is one of the mo. Michigan copper companies, and during 1913 suffered reduction in its output and profit. Copper produced 12,184,128 lb. against 20,634,800 lb. in 1912; receipts were \$1,921,198 against \$3,381,587; profit, \$257,840 against \$1,089,674; balance for dividends, \$76,160 against \$960,779; dividends, \$412,500 against \$550,000; and a surplus of \$896,938 compared with \$1,393,278.

The annual report of the Superior Copper Co. shows the following: 'Rock' stamped, 130,826 tons; copper output, 2,992,765 lb.; copper sold, 2,538,057 lb.; revenue, \$458,449; profit, \$93,912; balance of assets, \$193,697; cost per pound of refined copper, 12.86c. Good ore was opened on No. 17, 18, 19, and 20 levels south of the shaft on the West lode.

There was nothing special to note regarding the Tamarack Mining Co.'s work in 1913. Over half the 'rock' mined came from the Osceola amygdaloid lode. Water pumped from No. 1 and bailed from No. 5 shaft averaged 12,800,000 and 2,760,000 gal. per month, respectively. Plans are under way for a crushing mill to treat 1500 tons per day of sand from Torch lake. A leaching process being tried at the Calumet & Hecla mills may suit a portion of the product from the proposed plant. Results in 1913 were as follows:

| | |
|---|-----------|
| 'Rock' stamped, tons | 227,563 |
| Refined copper, pounds | 4,168,743 |
| Cost per pound, cents | 16.60 |
| Price received for 3,852,040 lb., cents | 15.45 |
| Total income, all sources | \$643,566 |
| Loss on operation | 48,373 |
| Balance of assets | 1,070,938 |

MONTANA**BLAINE COUNTY**

The Ruby Gulch Mining Co., at Whitcomb, will add to its electric plant equipment a 250-kva. alternating-current generator with 9½-kw. exciter, and has purchased the apparatus from the General Electric Company.

SILVERBOW COUNTY

The report of the East Butte Copper Mining Co. for 1913 contains the following data: The Company, since April 8, 1909, has operated the Pittsmtont property as well as its own. The main shaft was sunk 310 ft. in heavy ground, from 1275 to 1585 ft. Mine development consisted of driving a total of 2400 ft. on No. 6, 8, 10, and 12 levels; cutting out a station, and skip-loading pockets, and driving 1250 ft. on No. 15 level. A large tonnage of high-grade ore was opened on the 600-ft. level. Work in the upper levels was very satisfactory. At No. 15, sufficient work has not been done to reach any of the ore-shoots from No. 12 level. On account of a number of causes, mining was \$4.75 per ton, much higher than usual. It was intended to enlarge the furnace plant and equip it with mechanical chargers; but this will be done about the middle of 1914. Results were as follows:

| | |
|--|-------------|
| Ore treated, Company and custom, tons..... | 186,815 |
| Copper, pounds | 14,401,108 |
| Silver, ounces | 506,897 |
| Gold, ounces | 8,803 |
| Gross income | \$2,471,551 |
| Total expenses | 1,881,112 |
| Net income | 764,455 |
| Surplus after paying interest, development, equipment, etc. | 531,772 |

The Anaconda Copper Mining Co. has ordered a 150-hp. and two 100-hp. induction motors, with compensators and switchboard, from the General Electric Company.

The orebody recently cut at No. 14 level of the Butte & Superior is said to be 35 ft. wide, assaying 20% zinc and 7 to 8 oz. silver per ton.

During March the Butte & Superior mill treated 33,170 tons ore yielding 10,561 tons of concentrate, averaging 51.5% ic, with 90.05% recovery. Figures for March of last year were 20,140 tons, 7073 tons, 45.88% and 76.79% respectively.

NEVADA**NYE COUNTY**

A restraining order has been issued by the court stopping the West End company from mining ore in the disputed territory claimed by the Jim Butler company. Full details of the dispute are given in *The Tonopah Miner* of April 11.

STOREY COUNTY

The United Comstock Pumping Association has decided to install two Lakenan type hydraulic pumps for the 2500-ft. station in the C. & C. shaft. Each will have a capacity of 2200 gal. per minute to the Sutro tunnel, and will take the place of the Riedler and centrifugal pumps now at work.

From the 2350 and 2400-ft. levels of the Ophir mine, 127 tons of \$11.03 ore was mined last week. The Mexican mill treated 365 tons of Mexican ore worth \$6.29 and 281 tons of Monte Cristo ore worth \$7.57 per ton. The Pumping Association has completed its work at the 2500-ft. north drift.

WHITE PINE COUNTY

According to the March *Safety First* of the Nevada Consolidated Copper Co., there is a continued improvement in the casualty record at the mine, concentrator, and smelter. At Copper Flat there was only one serious injury; none at the Veteran mine; three minor accidents at the mill out of 23,000 shifts (750 men) worked; while at the smelter there were nine disabling accidents of no great importance. The Company's officials were instructed in first-aid, etc., during the month by the hospital doctors.

NEW MEXICO**SOCORRO COUNTY**

(Special Correspondence.)—In The Oaks mine, at a depth of 15 ft. below adit 'B', the vein is 4½ ft. wide, worth from \$15 to \$20 per ton. The Alberta Development Co. is to start shipping ore extracted during development. The Pacific mine is producing from 20 to 30 tons of ore per day. The Deadwood mill treated 350 tons of ore during the first week in April, yielding 4200 oz. gold and silver bullion, and 1½ tons of concentrate.

Mogollon, April 6.

OREGON**BENTON COUNTY**

(Special Correspondence.)—The Oregon Bureau of Mines and Geology, under the direction of H. M. Parks, is now preparing to place its field men at work. An attempt will be made to cover practically the entire state during the months of good weather. The wide area and many mineral industries of the state make this a large task, but the Bureau is now well organized and will be able to follow its work along more systematic lines than last year. Special attention will

MAP OF OREGON.

be given to gold-dredging in eastern and southern Oregon, to coal deposits in southwestern Oregon, and to building stone in northern Oregon. The deep mineral deposits of Baker and Josephine counties, carrying gold and copper, will also be investigated. From 6 to 20 men will be kept in the field during the summer and fall, and the reports will be prepared monthly.

Corvallis, April 3.

JACKSON COUNTY

(Special Correspondence.)—The old Braden mine, near Gold Hill, is one of the first properties in Oregon to take up the 'sliding-scale lease system' in its operation, by which a number of its operatives and employees derive a share of the returns. There are about 40 on the payroll, and some receive as high as \$200 to \$350 per month. This property is well equipped. O. A. Jackson, of Fort Worth, Texas, has purchased the old Opp mine, near Jacksonville, for \$200,000. It will be further developed and ore treatment changed considerably. A 20-stamp mill is on the property.

Gold Hill, April 8.

TENNESSEE**POLK COUNTY**

The annual report of the Tennessee Copper Co. for 1913 includes the following information: The physical condition of the Tennessee mine is said to be good. Ore reserves were

increased during the year and stood at 5,534,983 tons on December 31 as against 5,071,000 at the close of the preceding year. Certain changes are now being brought about, which, when completed, will place the Company in position to mine and handle an additional 1000 tons of ore per day. It has been demonstrated that it is more profitable for the Company to smelt its own ores than to do a custom-smelting business, and the additional equipment installed, it will be possible for Tennessee to maintain its maximum production of copper without ores from other properties.

UTAH

JUAB COUNTY

The May Day Mining & Milling Co. reports as follows for the year ended April 1, 1914: On account of the low price of spelter, shipments of zinc ore were stopped about the middle of the year. Parts of the mine to the 1000-ft. level were leased, and this plan has proved to be a good way of developing the property, and at the upper adit and 700-ft. levels orebodies were opened in new ground, according to C. C. Griggs, the superintendent, in his report to the manager, J. C. Dick. The ore from the adit averages 50% lead and 20 to 30 oz. silver per ton. The mine generally looks promising. Ore shipments were: lead, 1881 tons returning \$30,673, and zinc, 1474 tons returning \$12,815. With cash on hand of \$13,370, and other receipts, the revenue was \$58,117. Mine labor cost \$15,777, and payments to lessees \$13,430, while the cash on hand is \$14,777.

On the 200-ft. level of the Yankee Consolidated, 80 ft. of ore, supposed to be the Beck ore-shoot, has been opened. Development at 1700 ft. has cut a vein of good ore. In March the Gemini mine, operated by lessees, produced 2600 tons of ore averaging \$26.82 per ton. About 150 men are employed. John H. McChrystal is superintendent. The Iron Blossom company is paying 10c. per share, or \$100,000, on April 25.

SALT LAKE COUNTY

The Utah Consolidated Mining Co.'s report for 1913 shows the following: Copper ore reserves are estimated at 287,038 tons averaging 1.9% copper, 0.05 oz. gold, and 0.70 oz. silver; and lead ore reserves total 51,409 tons averaging 15.3% lead, 0.054 oz. gold, 3.27 oz. silver, and 0.98% copper. During the year 20,510 ft. of development and 2814 ft. of diamond-drilling was done. The metal output was 7,710,668 lb. copper, 19,208,063 lb. lead, 378,960 oz. silver, and 14,172 oz. gold from 181,077 tons of copper and 70,889 tons of lead ores, treated at the International Smelting & Refining Co.'s smelter. The total revenue was \$2,424,576; dividends, \$450,000; and surplus at end of 1913, \$772,096.

WASHINGTON

STEVENS COUNTY

The United Copper company will erect 12 five-room cottages and a hall for its married employees at Chewelah. The single men will also receive attention. The raise from the 1000-ft. level, to connect with a winze being sunk from the 600-ft. level in the ore recently cut, is up 30 ft. in ore.

CANADA

BRITISH COLUMBIA

During the week ended April 7 the Granby smelter treated 23,048 tons of ore and shipped 370,000 lb. of blister copper.

ONTARIO

At 550 ft. in the Hollinger mine, the vein has been cut, showing 10 ft. of ore. Foundations are finished for the new

power-plant on Gillies lake. The building is to be of concrete, 55 by 140 ft. in area. It will contain 4500-cu. ft. compressors and other equipment. In connection with this, a shaft is being sunk 230 ft. below the level of the lake, and pipes will be run down the shaft from the compressors to connect with an air-chamber, where the air will be stored and regulated by the pressure of 200 ft. of water from the lake. This plant will supply air for 110 drills for the Hollinger, Acme, and Miller-Middleton properties. The present Hollinger plant can supply 50 machines, although only 37 are in use, and 12 at the Acme or Dixon claims. The Canadian Mining & Finance Co., which controls these properties, is erecting the plant. Development in the Acme mine is producing good results. The Little Pet claim, near the Dome mine, has been sold for \$100,000 to Buffalo people, headed by C. L. Suerill. At 90 ft. in the Tough-Oakes there is 12 in. of ore averaging \$500 per ton. During March the Nipissing high and low-grade mills treated 184 and 6802 tons respectively, and the refinery shipped 696,737 oz. silver. A small rich vein was opened on No. 4 level.

COSTA RICA

The Abangarez Gold Fields company treated 6635 tons of ore in January, yielding \$36,561 at a cost of \$54,632.

KOREA

The Seoul Mining Co., operating the Suan Concession, in Whang Hai province, reports the following results for March 1914:

| | |
|--------------------------|----------|
| Stamps working | 40 |
| Time, days | 28.75 |
| Ore crushed, tons | 6,340 |
| Total recovery | \$47,832 |
| Operating expenses | 22,500 |
| Net earnings | 25,332 |

The Oriental Consolidated Mining Co. reports that in January the Kuk San Dong 40-stamp mill worked only 15 days, and the Tabowie 80-stamp mill 25 days, on account of ore and water shortage, respectively. The 240 stamps worked 24.7 days, crushing 24,705 tons, yielding \$143,757. The net profit was \$47,292. In February the tonnage of 21,954 \$149,084. There was a further shortage of water, are working at the Kuk San Dong mine. It is intended to lease the Candlestick mine, and large numbers of Koreans came to the property to be on hand to get a portion. The Taracol cyanide plant treated 1797 tons of concentrate, yielding \$45,576, with 83% recovery. The results are gratifying.

MEXICO

GUANAJUATO

At the El Durazno y Anexas property, in the Santa Rosa district, owned by Fernando Rubio Rocha, considerable work is under way. The San Nicolas del Monte vein is being developed. This orebody is also in La Asuncion ground. A 2.5 by 2.5-metre adit has been driven 425 metres into the former property. Small shipments have returned 17 kg. silver and 900 gm. gold per ton.

JALISCO

The Mutual Mining & Milling Co., of Mexico City, owning the Zapote group of copper mines in the Ameca district, probably will have its 25-ton concentrating plant ready for operation during the coming month. Some high-grade ore will be sent to the Aguascalientes smelter. The Magistral-Ameca Copper Co., owning the Magistral copper mines in the Ameca district, has started to take down the concentrating plant which was erected at the mines several years ago, and this will be rebuilt along new lines. The plant was originally designed for the treatment of ores by a flotation process. Shipments of high-grade ore to the Aguascalientes smelter will shortly be increased to 10 carloads per month.

Personal

B. H. DUNSHÉE is in Oakland for the month.

CHARLES A. CHASE was in San Francisco recently.

W. H. BLACKBURN has been in Los Angeles recently.

G. W. METCALFE was in San Francisco last Saturday.

J. PARKE CHANNING was expected at Payson, Arizona, last week.

D. W. BRUNTON was examining property in Mariposa county last week.

WILBUR H. GRANT has opened an office in the Holbrook building, San Francisco.

H. FOSTER BAIN is visiting the Searles Lake deposits of the American Trona Company.

H. V. WINCHELL and WALTER H. WILEY are at Tonopah in connection with the West End v. Jim Butler litigation.

A. D. BROKAW has been appointed assistant professor of mineralogy and economic geology in the University of Chicago.

GEORGE M. TAYLOR, general manager of the milling department of the Portland Gold Mining Co., was in San Francisco this week.

C. R. FORD, formerly with the National Mines Co., of National, Nevada, is now with the Alkalai Mines Co., of Eureka, Nevada, under the same management.

GEORGE H. GARREY, formerly chief geologist for the American Smelting & Refining Co., has opened an office as consulting mining geologist at 115 Broadway, New York City.

THE AMERICAN ELECTROCHEMICAL SOCIETY'S twenty-fifth general meeting is to be held in New York City on April 16, 17, and 18, at the Chemists' Club. Among the excursions are visits to plants of the American Smelting & Refining Co. and the United Lead Co. The papers to be presented number over 30, those of interest to mining men are as follows: 'Progress in Leaching and Electrolytic Treatment of Copper Ores in South America,' by E. A. Smith (this is really a lecture); 'Hydro-electrometallurgy of Copper,' by Robert R. Goodrich; 'Leaching of Copper Tailings,' by Rudolph Gahl; 'Metal Inventory in an Electrolytic Copper Refinery,' by Ralph W. Deacon; 'Electrolytic Zinc,' by Joseph W. Richards; and 'Sane Economics in the Use of Energy in Electric Furnaces,' by F. A. J. Fitzgerald.

THE INSTITUTE OF METALS held its annual general meeting in London during the third week in March. The president, vice-admiral Sir Henry Oram, gave an address on modern warship machinery. Regarding condenser tubes, he said that the worst trouble was caused by their splitting while at work, in fact, they became a menace to the efficiency of the fleet. In 1908, out of 2,500,000 tubes there were 90 failures; but in 1912 and 1913 there were only 131 failures out of 3,800,000 tubes at work.

THE ILLINOIS MINERS' AND MECHANICS' INSTITUTES, under the direction of R. Y. Williams, have authority to promote the technical efficiency of persons working in and about mines of the state, and to assist them to better overcome the increasing difficulties of mining. There are 79,411 men employed at the coal mines. *Bulletin* No. 2 outlines the methods to be used in this work, and the subjects of instruction.

BULLION received at the San Francisco Mint in March was as follows: gold, 163,068.984 fine oz.; and silver, 15,432.84 fine oz., with total value of \$3,379,577.48. The coinage executed was \$2,154,000, and ₱43,000 for the Philippines.

Schools and Societies

THE Chicago section of the Illuminating Engineering Society met on April 10, when papers on railway signals were discussed.

EFFICIENCY SYSTEMS and their effect on industrial relations were considered by the United States Commission on Industrial Relations at public hearings held in Washington, D. C. on April 13, 14, and 15.

LEHIGH UNIVERSITY students, on March 28, visited the Cornwall Ore Banks Co.'s mine at Cornwall, Pennsylvania, and on April 4 inspected the mine of the Empire Steel & Iron Co. at Mt. Hope, New Jersey.

THE FOREST PRODUCTS EXPOSITION, to be held at Chicago in the Coliseum, April 30 to May 9, and at New York in the Grand Central Palace, May 21 to 30, inclusive, gives every assurance of being one of the most representative and comprehensive industrial expositions of this kind which has been held in the history of the industry.

The Metal Markets

LOCAL METAL PRICES

San Francisco, April 16.

| | |
|---|-------------|
| Antimony | 9 — 9¾c |
| Electrolytic copper | 15½—15¾c |
| Pig lead | 4.05 — 5.00 |
| Quicksilver (flask) | \$39.00 |
| Tin | 40½—42 c |
| Spelter | 6½—6¾c |
| Zinc dust, 100 kg. zinc-lined cases, 7½ to 8c. per pound. | |

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, April 16.—There is not much to note about the market, copper being practically stationary, with little business being done; lead is quiet, and spelter is weak. Bar silver is 58¼c. per ounce. Tin is weak at 35.85 to 36.15c. Antimony is dull, Cookson's being quoted at 7.25c. Trading on the Stock Exchange is improving, but uneasiness prevails in financial circles. In London, lead is £18; spelter, £21 10s.; copper, £64 15s.; and tin, £164 15s. per ton, respectively; and bar silver steady at 26.81d. per ounce.

SILVER

Below are given the average New York quotations in cents per ounce, of fine silver.

In spite of the small movements in prices during the week ended March 26, business has been more brisk, according to Pixley and Abell, of London. Most of the buying has come from the Indian bazaars, some of it for shipment by this week's steamer, which takes approximately £200,000, and some in anticipation of their requirements later on. The Continent also has bought moderately. Trade in China is very quiet, and, although a few selling orders have been in evidence, the amounts were insufficient to depress rates. Owing to some liquidation of the bull account, the cash position has for the time being become easier, and cash and forward have been quoted at the same level since April 20, but as most of this silver was bought for consumption, and supplies will be restricted for some months, future cash demand will not be easily met, especially as the bull account is now a negligible quantity. It is possible, however, that, as the bazaars have bought freely just lately, there may be a period of quietness and therefore the effect of small stocks may take a little time to influence rates. The decline in the production of Mexico during 1913 is important, and it is probable that since January 1 of this year the rate of production has been still further decreased.

COPPER

Quotations on copper as published in this column represent average wholesale transactions on the New York market and refer to electrolytic copper. Lake copper commands normally 1-5 to 1-4c. per lb. more. Prices are in cents per pound.

Figures showing the production of metallic copper last year in Russia are now published and show that between 1913 and

1912 little progress was made. This is due to a considerable reduction in the quantity of copper produced in the Urals mining district. In the other copper-producing areas good progress has been made. The quantity produced last year made 2,095,000 poods (1 pood weighs 36 lb.), against 2,047,000 in 1912 and 1,564,000 in 1911. The tendency of Russian copper production is not toward a decline, but on the contrary it is still making for greater progress than ever. Several of the large Urals smelters are being transformed and have therefore been laid idle for this particular purpose. Obviously, therefore, while the period of transformation necessitated a setback in the production, it indicates a more intensive production than ever in the near future.

German copper consumption during January and February was 34,433 tons, against 30,875 tons in 1913. Of the 1914 consumption, 30,902 tons was imported from the United States, according to L. Vogelstein & Company.

LEAD

Lead is quoted in cents per pound or dollars per hundred pounds, New York delivery.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Copper and Spelter Production

The following table shows the production of these metals, in metric tons, during the past 10 years, and how one has kept pace with the other:

| | Copper: | | Spelter: | |
|----------------------|-----------|-----------|-----------|-----------|
| | Produc- | Consump- | Produc- | Consump- |
| | tion. | tion. | tion. | tion. |
| 1913 (estimated) ... | 1,000,716 | 1,020,000 | 1,001,100 | 1,046,000 |
| 1912 | 1,019,800 | 1,040,200 | 977,900 | 987,500 |
| 1911 | 893,400 | 953,700 | 902,100 | 903,200 |
| 1910 | 887,900 | 913,700 | 816,600 | 827,000 |
| 1909 | 849,200 | 787,500 | 783,200 | 798,900 |
| 1908 | 757,800 | 706,500 | 722,100 | 730,500 |
| 1907 | 712,000 | 663,600 | 738,400 | 743,200 |
| 1906 | 720,600 | 722,600 | 702,000 | 705,200 |
| 1905 | 693,900 | 727,400 | 658,700 | 663,800 |
| 1904 | 647,900 | 662,500 | 625,400 | 629,300 |

The value of the 1913 output is approximately \$330,000,000 and \$113,000,000, respectively. The United States produces 56% of the world's output of copper and 32% of the spelter.

Portland Cement Production

Final figures for the portland cement industry in 1913, as obtained by the U. S. Geological Survey on March 16, show a production of 92,097,131 bbl., shipments of 88,689,377 bbl., and stocks on hand 11,220,328 bbl. It is somewhat interesting to compare these figures with the estimates made by the Survey on January 15. These estimates were as follows: production, 92,406,000 bbl.; shipments, 88,853,000 bbl.; and stocks on hand, 11,375,000 bbl., the percentage of error ranging from only 0.003 in production to about 0.01 in stocks on hand.

IRON ORE at Lake Erie docks on April 1 amounted to 6,925,678 tons, against 6,728,035 on the same date of last year. Shipments from docks to furnaces were 820,741 tons, the lightest for three years.

Company Reports

DREDGING COMPANIES IN VICTORIA, AUSTRALIA

During the three months ended February 28, 30 dredges in the Bright district produced 8138 oz. of gold, valued at \$154,000. During the term the following companies paid dividends: Reliance, \$11,520; Confidence, \$5280; Owens Valley, \$3510; Wandiligong, \$10,080; Porepunkah, \$2400; Buckland Star, \$1920; Buckland River, \$1680; Phoenix Syndicate, \$1680; Excelsior, \$1440; Maori Queen, \$2010; Kia Ora, \$1100; and Harrietteville Star, \$1200; a total of \$43,850.

TEWKSBURY AMALGAMATED GOLD DREDGING CO., VICTORIA

During the half-year ended December 31, 1913, only three dredges out of five were in commission. They handled 447,792 cu. yd. of gravel, yielding 6.3c. per yard. The average cost was 5.57c. per yard. Only two boats worked at a profit, while the profit was only \$3400. The managing director, P. W. Tewksbury, does not hold out much encouragement for further work.

WANDILIGONG GOLD DREDGING CO., VICTORIA

During the half-year ended on January 31, 1914, this Company, with two boats at work, treated 265,893 cu. yd., yielding 1536 oz., valued at \$30,250. The total output to date is 19,007 oz., worth \$370,000. The paid-up capital of the Company is only \$25,920, but it has paid \$103,250 in dividends, or \$17.20 on each \$5 share. The Company's claims are approaching exhaustion, particularly that area allotted to No. 2 dredge, which has only a few months' work left, while No. 1 plant has about 12 months' work before it. The Company has \$6480 on fixed deposit and a cash balance of \$9120.

TOLIMA MINING COMPANY, LIMITED

This Company owns the Frias silver mines, a property of 3000 acres in Tolima, Colombia. The report for the year ended June 30, 1913, gives the total amount of mineral exported during the year as 896 tons, with an average assay value of 467.9 oz. silver per ton. The price of silver for the year gave an average of 29¾ d. per oz., and the profit on revenue account was \$25,000. During the year 17,134 tons of ore was raised to the surface, which gave 9720 tons of ore for cobbing and treatment in the mill producing 884.69 tons of mineral for export, having an average assay value of 469.92 oz. silver per ton, giving a total production of 415,740 oz. of fine silver. The lead content gave an average for the year of 15.7%; the value of the lead contained was \$11,500. Reserves were estimated at 1448 tons averaging 400 oz. per ton. The prospects of the mine are good. A dividend of 12c. per share was paid.

OLD DOMINION COPPER MINING & SMELTING CO. UNITED GLOBE MINES COMPANY

This Company operates at Globe, Arizona, and the report covers the year 1913. A total of 169,961 tons of three grades of ore was mined, averaging 5.88% copper, at a cost of \$4.78 per ton. On account of various improvements in the mine, it was not until December that operations underground were normal. The new crushing and sampling plant has a capacity of 100 tons per hour. A geological department was organized toward the end of the year, and better results from prospecting and development are expected. The new 500-ton concentrating plant will hardly be running before next August. Results were as follows:

| | |
|----------------------|------------|
| Copper, pounds | 31,061,645 |
| Silver, ounces | 193,845 |
| Gold, ounces | 4,254 |

Of this, 12,116,492 lb. copper, 142,528 oz. silver, and 3835 oz. gold was obtained from custom ores.

| | |
|--------------------------------|-------------|
| Revenue from all sources | \$3,057,107 |
| Profit | 1,043,793 |
| Dividends | 810,000 |
| Surplus at end of 1913 | 1,193,247 |

The United Globe Mines Co. is controlled by the old Dominion company. Its report for last year shows that the most important development was on the No. 16 level, where from 16 to 30 ft. of 3.5 to 7% copper ore was opened. The flow of water on this level is about 650,000 gal. per day. A 100,000-cu. ft. fan was installed at the Kingdom shaft and has improved the ventilation. An electric hoist and new change house are to be erected at the Grey shaft. A total of 167,917 tons of oxidized, sulphide, concentrating, and silica lining ores was mined, including 5084 tons of old slag. The revenue was \$1,221,052; expenses, \$739,606; and profit, \$481,445. With the previous surplus the sum available was \$1,062,739, of which \$690,000 was paid in dividends, leaving the present surplus of \$372,739.

UNITED STATES SMELTING, REFINING & MINING COMPANY

Operations conducted by this well known Company at its mines and smelters in the United States, and mines in Mexico, resulted as follows in 1913:

| Metal output. | 1913. | 1912. |
|----------------------|------------|------------|
| Copper, pounds | 20,239,973 | 21,152,620 |
| Lead, pounds | 58,116,504 | 56,385,769 |
| Silver, ounces | 13,089,708 | 12,059,829 |
| Gold, ounces | 148,372 | 140,183 |

The average price received for the metals was copper, 15.433c.; and lead, 4.396c. per lb.; and silver, 60.503c. per ounce.

Income account for the past two years shows the following:

| | 1913. | 1912. |
|--|-------|-------|
|--|-------|-------|

| | | |
|--|-------------|-------------|
| Earnings of all companies, less production cost, etc. | \$4,555,122 | \$5,497,965 |
| Depreciation, improvements, etc. | 969,536 | 1,265,000 |
| Profit | 3,585,586 | 4,232,965 |
| Preferred dividends | 1,702,144 | 1,702,120 |
| Common dividends | 1,053,322 | 877,762 |
| Surplus | 830,120 | 1 |
| Previous surplus | 3,648,722 | 2 |
| Total surplus | 4,478,842 | 3,648,722 |

The assets include ores and matte, \$1,011,112; supplies of fuel and timber, \$1,392,273; metal in ore and on hand, \$3,148,897, and cash, \$3,455,647.

The coal properties in Utah, controlled by a subsidiary company produced 869,522 tons of coal, 40% over that of 1912, and the profits were equivalent to 4.35% on the investment, after providing for certain changes. The Bingham mines produced 78,165 tons of lead and 123,757 tons of copper ores. Work was started on the Niagara mine. From the Centennial-Eureka 100,442 tons of lead-copper-silver ore was mined. Developments were fairly satisfactory. The Midvale smelter worked throughout the year. Further improvements are to be made. The concentrating mill and Huff electrostatic separating plant did good work. The lime company produced 109,224 tons of limestone. The Mammoth copper mine in California is opening well. The lead refinery at Grasselli, Indiana, and the copper refinery at Chrome, New Jersey, were improved, and worked steadily, as also did the smelter at Chrome. In Arizona the Gold Road mine yielded 103,628 tons of ore. The mine is looking fair but the average ore developed was rather low. The Needles mill worked continuously, but the smelter only a short time. The Real Del Monte y Pachuca mines in Mexico worked without interruption. The monthly tonnage has been increased from 36,000 to 50,000 tons, while additions to the mills will further increase the output. Ore reserves in the eight mines being operated are larger than before. Additional ground has been secured. The Last Chance claims, at Bingham, Utah, were acquired and developments appear promising.

Monthly Copper Production

AHMEEK COPPER MINING CO., Kearsarge, Michigan. \$1,-250,000 in \$25 shares; 24,796 shares owned by Calumet & Hecla; 1800-ton mill at Hubbell; concentrate smelted by Calumet & Hecla smelter. Total in 1913, 9,100,000 pounds.

ALLOUEZ MINING CO., Allouez, Michigan. \$2,500,000 in \$25 shares; controlled by the Calumet & Hecla, which owns 43,000 shares and \$250,000 in notes of the Company; ore is milled by the Lake Milling, Smelting & Refining Co., in which the Allouez owns half. Total in 1913, 4,091,129 pounds.

ANACONDA COPPER MINING CO., Butte, Montana. \$108,312,-500 in \$25 shares; controlled through Amalgamated Copper Co. by Thos. F. Cole, J. D. Ryan, and Standard Oil interests; 10,000-ton concentrator and smelter at Anaconda; 5000-ton concentrator and smelter at Great Falls, Mont.; also 70-ton electrolytic refining plant at Great Falls. Production figures include copper from all companies which ship custom ore to Anaconda smelters.

Book Reviews

ELECTRO-THERMAL METHODS OF IRON AND STEEL PRODUCTION. By John B. C. Kershaw. P. 233, Ill., index. D. Van Nostrand, New York, 1914. For sale by *Mining and Scientific Press*. Price \$3.

In this book Mr. Kershaw has amplified and brought up to date the information given by him in 1907 in his well known 'The Electric Furnace in Iron and Steel Production'. The first two chapters include a general sketch of the principles involved in electric heating and the broad lines of designing furnaces for iron and steel making. The succeeding chapters are mainly taken up with consideration of various furnaces in actual use. As Mr. Kershaw is not connected in a business way with any of the companies or patentees concerned in selling these furnaces, his review is especially valuable. The book is an excellent guide to knowledge of just what is now being done in this important field.

THE PETROLOGY OF THE IGNEOUS ROCKS. By F. H. Hatch. P. 454, Ill., index. George Allen & Co., Ltd., London, 1914. For sale by *Mining and Scientific Press*. Price \$4.25.

This is volume I, 'The Igneous Rocks,' of the well known 'Text Book of Petrology,' of which the first edition appeared in 1892. A companion volume on the 'Petrology of the Sedimentary Rocks' forms the second volume of the series. In this the seventh edition there has been considerable change. New chapters on 'Pyroclastic Rocks' and 'Metamorphic Derivation of the Igneous Rocks' have been added, and numerous additional illustrations have been used. The book is a brief, general, but excellent summary of essential facts regarding the physical characters, constituent minerals, and classification, of igneous rocks in general with three chapters on the distribution of igneous rocks in Great Britain.

OIL PRODUCTION METHODS. By Paul M. Paine and B. K. Stroud. With a chapter on 'Accounting System,' by W. F. and B. Sampson. P. 239, Ill., index. Western Engineering Publications, San Francisco, 1913. For sale by *Mining and Scientific Press*. Price \$3.

There have been few books on the technology of oil production and those that have been published have been general and in the main based upon European practice. Redwood's three volume work includes a number of chapters upon drilling methods, but even so large a book does not find room for much that is modern and significant. Many years ago the Pennsylvania Geological Survey issued an excellent description of practice in that state, but the book is long since out of date and methods have greatly changed. Mr. Paine and Mr. Stroud describe the methods in actual daily use in California, and they write from first hand knowledge. Their book accordingly is up to date, authoritative, and extremely useful to those interested in the oil industry.

THE ENGINEERING INDEX, ANNUAL FOR 1913. Compiled from the 'Engineering Index,' published monthly in *The Engineering Magazine* during 1913. P. 508. *The Engineering Magazine* Co., New York, 1914. For sale by the *Mining and Scientific Press*. Price \$2.

This is the thirtieth year that the index has been made and this is the twelfth of the annual volume reprints. The work is too well known to require extensive review. It covers all branches of engineering from Civil to Industrial Economy, and while some papers escape the vigilant eye of the compiler, it can be relied upon to cover most of the important ones. It is well printed and well arranged and will be especially helpful to mining engineers and metallurgists who wish to keep in touch with engineering in its broader aspects.

Industrial Progress

An American Locomobile

The locomobile is a self-contained engine-boiler unit, designed to use superheated steam and increase over-all efficiency by decreasing radiation losses. The name is best known in the United States from the fact that an engine of this type was used on one of the pioneer automobiles.

A BUCKEYEMOBILE POWER-PLANT.

Essentially a locomobile consists of a high-class compound engine mounted upon its boiler, with the cylinders in the smoke box, the steam passing from the superheater directly to the high-pressure cylinder, and from this through a reheater directly to the low-pressure without outside piping. The condenser and feed pumps are run from the engine itself. Above is presented a view of such an engine, built by the Buckeye Engine Co., and marketed under the name Buckeyemobile. A number of these are giving excellent results.

The analysis of a test of one such engine, as reported by F. R. Low in *Power*, is printed below:

TEST RESULTS OF BUCKEYEMOBILE.

The engine developed an indicated horse-power on less than 9.75 lb. steam per hour, and the coal curve is, as will be noted, particularly flat. This unit delivers a kilowatt for about $2\frac{1}{2}$ lb. of coal per hour, an indicated horse-power hour for less than $1\frac{1}{2}$ lb. when condensing, and a little more than 2 lb. non-condensing. As these engines run at very high temperature, special oils are necessary for lubrication, but that difficulty has been successfully met. A wide range of fuels can be used.

EDITORIAL

A GOLD discovery is reported from Sundance, Wyoming, assays as high as \$1960 per ton being quoted, with the richest of the samples yet untested. According to the *Centennial Post*, "a number of nuggets have been found near Devil's Tower, and the theory has been advanced that the tower is the core of the crater of an ancient volcano and may be filled with gold." It is to be regretted that this said volcano is extinct, but no doubt the author of the theory that it "may be filled with gold" can devise some method to rejuvenate the volcano and put it in the producing class again.

THE fiftieth anniversary of the founding of the School of Mines of Columbia University will be fittingly celebrated on May 28 and 29 by a reunion of the School of Mines graduates, which will be in the nature of a congress at which will be discussed some of the problems of modern mining engineering practice. Honorary degrees will be given to some of the distinguished alumni and the first lecture on the 'Chandler Foundation' will be included in the program. As the alumni roll of the School of Mines includes many of those whom the industry has recognized as leaders in the profession, and who will be present at this meeting, a most interesting session is assured and a large attendance is anticipated.

IN a recent address before the Chemical Society of the Massachusetts Institute of Technology, Mr. Arthur D. Little pointed out to the undergraduates of that institution the importance of clearness and simplicity in engineering reports. The difference in perspective of the technologist and layman is a subject which is often forgotten by the engineer when writing his report. As a result, the subject matter is so obscured in technical phraseology, which is meaningless to the non-technical reader, that it is valueless to a large number of those for whom it was prepared. It should, therefore, be the purpose of the engineer to present the results of his investigation in a manner which is intelligible to the non-technical mind. The success of an engineer is influenced in no small degree by his ability to impart to others his technical knowledge in terms which are understood, and therefore the cultivation of correct English should be an essential part of his training.

STEAM-SHOVEL work is in high favor at the copper mines and is proving to be adapted to many situations in which underground mining methods have heretofore been supreme. At the Utah Copper Company all underground work has finally been abandoned. At the Chino it is possible that all ore will eventually be mined by steam-shovels and at Ely it is said that plans for converting the Ruth mine into an open pit have been worked out and are now under most careful consideration. Experimental work with flotation has proved that Ely ores are well adapted to the process, and it is said that announcement that a flotation plant is to be built may be expected.

QUESTIONS of nomenclature have been at the bottom of many a stubborn controversy among scientific men. Indeed, rather more than others, they attach deep significance to priority and exactness in definitions. This is excellent in itself, but on more than one occasion insistence on minor matters has served to retard rather than advance scientific knowledge. At Kalgoorlie, due mainly to the independent investigations of Mr. Malcolm Maclaren and Mr. C. O. G. Larcombe, two sets of names have been applied to the same rocks. The result has been confusion which might readily have become worse except for the sensible action of the two geologists mainly concerned. We called attention to the situation last year at the time that we printed Mr. Maclaren's series of informing articles on the geology of the district, and we print this week a letter from Mr. Larcombe in which he proposes a modified system of nomenclature designed to smooth away the difficulties in the way of further discussion. Mr. Maclaren, having read the paper and consulted with Mr. Larcombe, asks us to say that he agrees to the changes proposed, and there can, therefore, be no necessity for further confusion. We are glad to have had a part in bringing this about, and we commend to others the spirit of mutual accommodation exhibited by Messrs. Maclaren and Larcombe. Possibly because they are mining geologists and so more concerned with results than theories, they have been entirely willing to sacrifice personal claims as authors to prevent possible confusion. We may differ, tolerantly let us hope, in our interpretations, but let us agree, as far as may be, in using the same name for the same thing. This will make for progress in the industry.

MINING in Australia is exceedingly dull at present. This country, which has produced minerals to the value of approximately \$3,985,000,000 to date, needs another Ballarat, Bendigo, Broken Hill, Charters Towers, or Kalgoorlie to give it a new lease on life. The most promising district at present is Broken Hill, where improved metallurgical methods have put new life into the industry. Kalgoorlie is busy with geological problems, and the other once-important districts are steadily declining. Chillagoe, Great Fitzroy,

and Mount Perry, three of Queensland's big copper mines, have suspended operations recently and several gold mines in Victoria have also been closed. The dredging industry of this state is being hampered by legislation, and what the outcome will be is not known. Great Cobar has been having trouble and the Junction mine at Broken Hill, which has been on the decline for a number of years, is now for sale. Tasmania is practically holding its own in mineral production, although the Tasmania gold mine is to be shut down. In Western Australia, the Victorious, Burbank's Main Lode, and Associated Northern mines are not operating at present, and reduced returns are coming from the Bullfinch. The Ivanhoe recently had a fire and is laboring under a handicap. While there is nothing new in South Australia, it is hoped that trans-Australian railways will develop new mineral districts, and that the investigations in the Northern Territory will result in a new field being opened. With the ever-increasing wages and present prices, metal mines of Australia are reported as generally depressed, and the optimists of the industry are in the decided minority.

SEIZURE of Vera Cruz by the American marines marks the culmination of a long series of insults to the American flag and American people by the *de facto* government of Mexico. The Mexican policy of President Wilson has been for peace, with the hope that the time was not far off when Mexico would settle her internal troubles and set up a government worthy of recognition. This policy, which has only obtained through the will of the President, has been the subject of repeated abuse by the Huerta government; over 150 American lives have been sacrificed through lack of protection, American industries in Mexico have in great part either dwindled to nothing or suspended operations completely, the American nation has been singled out for insult, and the American government has been antagonized by the officials of the Huerta administration to beyond endurance. The unhappy affair at Tampico placed the President and administration in the position of either being held up to ridicule by the American people and nations of the earth for permitting of this further insult, or insisting upon a formal acknowledgment of the many grievances which the American people bore against the Huerta administration. The latter alternative was chosen, and rightly so. It is to be hoped that this step toward the ultimate fall of the *de facto* government in Mexico, will not mean war and the invasion of Mexican territory by American troops, but that the seizing of the Mexican ports and the cutting off of military supplies and revenue will hasten the downfall of Huerta and bring the Mexican people to realize that a legally constituted government and the blessings of peace can only be obtained by active coöperation among themselves. The present civil war is leading to nothing. The Mexicans must put country above party if they expect others to respect their country.

Spelter and Lead in 1913

The world's production of zinc for the year 1913, according to statistics published by the United States Geological Survey and various consular reports amounted to 1,103,359 short tons, which is an increase of 33,314 tons over the production of the previous year. Of this output of spelter, the United States was the largest producer, with a production of 346,676 tons; Germany was second, with 311,914 tons; and Belgium third, with 217,941 tons. The imports of zinc into the United States during the year 1913 were valued at \$722,962, as compared with \$1,363,884 for the previous year. The exports from the United States for 1913 amounted to \$1,735,099, while that of the preceding year was \$1,846,301.

In Australia almost the entire spelter production was practically confined to the Broken Hill district of New South Wales, where the zincblende production was of minor importance until the advent of flotation methods when the old tailing dumps, together with the zinc-bearing tailing from the lead concentrators, had been made to yield a good profit. The development of a treatment for these ores forms one of the most interesting chapters in the zinc metallurgy, beginning with the Potter acid flotation experiments in 1901 and subsequent developments in acid and oil flotation, until in 1909 the problem passed from the experimental stage, although several years previous to this large tonnages of zinc ores were being successfully treated by flotation methods. The advance which has taken place in zinc mining and metallurgy in the treatment of Australian ores is evidenced by the production of zinc concentrates, which has advanced from 97 tons, valued at \$4808 in 1889, to 516,378 tons valued at \$6,885,999 in 1911. Practically all of this concentrate is smelted in the European smelters of Belgium and Germany, though some is treated locally at the Port Pirie smelter of the Broken Hill Proprietary Mines Company.

The zinc concentrate production of Austria for 1912 amounted to about 34,674 tons, valued at \$577,451; of this amount about one-half was devoted to government uses, according to a consular report. The Hungarian production is not significant, amounting in 1912 to only 857 tons valued at \$13,961. The Hungarian government is reported to be endeavoring to stimulate an interest in zinc mining and smelting and a natural gas smelter is proposed for Transylvania. During 1912 the zinc imports into Hungary were valued at \$981,919. The German production for the year 1913 was 311,914 tons of spelter, a material increase over the production of the previous year, which was 298,794 tons. The imports and exports of both zinc oxide and lithopone showed an increase during 1912, the exports of oxide amounting to 28,731 long tons, as compared with 20,994 tons for the previous year. The exports of lithopone increased from 13,742 tons in 1911 to 15,117 tons in 1912. The Italian mines during 1913 produced about 100,000 tons of zinc concentrate, which

was shipped to the smelters of France and Belgium.

While zinc ores are found in association with silver and lead ores in various parts of the Caucasus mountains, the principal production at the present time is from near Sadon in the Vladikavkaz district of the Tersky province. The total production of silver, lead, and zinc ores in the Caucasus in 1912 is reported by the mining department of the Caucasus to have been 28,495 tons, as compared with 26,060 tons for the preceding year. In the Olkusz district there was a production of 48,427 tons of zinc carbonate and 18,768 tons of zinc carbonate carrying some lead. The latest available statistics from Spain are for the year 1911, during which period 162,140 long tons of zinc ore valued at \$1,213,649 was mined. Most of the production came from the provinces of Murcia, Santander, and Cordoba. The exports of blende and calamine for 1911 amounted to 127,632 long tons valued at \$1,188.83. Zinc as bars and sheets totaling 2336 long tons and valued at \$294,370 was exported, the finished product going to France, Great Britain, Argentina, and the Netherlands.

Statistics of the world's lead production for 1913 are not yet available, but final figures for the production of the United States, as compiled by Mr. C. E. Siebenthal of the United States Geological Survey, have recently been printed. According to his figures, the total production of refined lead made from ore amounted to 462,460 tons of 2000 pounds. This agrees closely with the preliminary estimate of 466,843 tons that we printed, through the courtesy of the Geological Survey, on January 3. In 1912, the primary lead production was 480,894 tons, and there was accordingly a decrease of 18,434 tons, equivalent to 3.8 per cent. The secondary lead, obtained from skimmings, drosses, old metals, etc., amounted to 67,168 tons in 1912, and is estimated at 72,834 tons for 1913, though this is subject to slight revision. Part of this secondary lead, 39,730 tons, was recovered in the form of alloys. As we have previously noted, there are no figures of lead consumption in the United States. Mr. Siebenthal estimates the primary lead "available for consumption" in 1913, at 419,485 tons, basing this estimate on the following figures: stock in bonded warehouses January 1, 10,492; imports for consumption, 11,980; imports for warehouse, 45,165; production from domestic ores, 411,878; total supply, 479,515. The amounts withdrawn were as follows: exports of foreign lead from warehouse, 44,544; in manufactures with drawbacks, 9757; decrease by liquidation, 419; stocks in bonded warehouse, December 31, 5310; total withdrawn, 60,030 tons.

Of the total lead production, 301,160 tons is classified as desilverized, and 131,867 as soft lead. The latter showed a decrease of about 10,000 tons. There were also 29,433 tons of desilverized soft lead, and 14,667 tons of antimonial lead. A curious feature is that a small amount of soft lead from Wisconsin and of desilverized from Idaho found its way to Canadian smelters.

While it is impossible to apportion the product ex-

actly according to the source of the ore, since the statistics are based upon returns from smelters and refiners who do not, in all cases, know the exact source, the following fairly accurate distribution of the production is made:

| Domestic ore: | 1912. | 1913. |
|--|---------|---------|
| Alaska | 45 | 6 |
| Arizona | 3,891 | 4,901 |
| California | 811 | 3,294 |
| Colorado | 37,039 | 42,840 |
| Idaho | 127,780 | 137,892 |
| Illinois | 513 | 619 |
| Kansas | 1,937 | 1,504 |
| Kentucky | 91 | 16 |
| Missouri | 162,610 | 152,430 |
| Montana | 2,517 | 3,256 |
| Nevada | 5,699 | 6,142 |
| New Mexico | 2,511 | 1,821 |
| North Carolina | 34 | 10 |
| Oklahoma | 2,509 | 3,214 |
| Oregon | 21 | 37 |
| South Dakota | 12 | 7 |
| Texas | 30 | 108 |
| Utah | 60,664 | 71,069 |
| Virginia | 85 | 878 |
| Washington | 53 | 9 |
| Wisconsin | 3,301 | 2,639 |
| Undistributed | 120 | 63 |
| Zinc residue | 3,131 | 3,765 |
| Total from domestic ore..... | 415,395 | 436,430 |
| Foreign ore: | | |
| Africa | 1,774 | 5,976 |
| Canada | 29 | 16 |
| Mexico | 7,407 | 4,512 |
| South America | 2,332 | 2,617 |
| Other foreign | 30 | 102 |
| Foreign base bullion: | | |
| Mexico | 76,805 | 37,359 |
| Total from foreign ore and base bullion | 88,377 | 50,582 |
| Grand total, derived from all sources..... | 503,772 | 487,012 |

In the figures of consumption, lead in ore, base bullion, pigs, bars, and old metal are included. Decrease by liquidation covers losses in smelting and refining in bond and other corrections. Warehouse stocks cover only lead of foreign origin, as it has been found impossible to obtain complete figures of domestic stocks. Of the imports the bulk, amounting to 95,000,000 out of 114,000,000 pounds, came from Mexico as usual. The total imports, however, have decreased steadily since 1908. There has been a growth of imports from South America, from 469,770 pounds in 1908 to 8,766,327 pounds, and an even greater increase in imports from other countries, but the decline in Mexican imports more than offsets this. Mr. Siebenthal's figures afford the one measurably complete and accurate insight into the lead industry of the country that it is possible to obtain each year, and it is a pleasure to note that they are showing increasing detail. We see no reason why the lead producers should not cooperate in collection of monthly statistics as the copper pro-

ducers do, but so far, trade jealousy and the fact that the American Smelting & Refining Company controls 65 per cent of the production has prevented. We trust that this may soon be a matter of the past, as complete, accurate, and prompt statistics are the best of bases for sane trading and the furthering of industrial development.

End of Copper Miners' Strike

Workers in the copper mines of the Lake Superior district have officially declared the strike to be over, and the Western Federation of Miners remains unrecognized by the mining companies of that district. While the mines of the district have been working at about normal capacity for the past two months, this official acknowledgment on the part of the men of a willingness to return to work marks the climax of a labor struggle which was doomed to failure at the outset. It would seem after a strike lasting from July 23 of last year until the present, at a cost to the Western Federation of over \$1,000,000 in addition to the loss in wages and hardships endured, that the men who have borne the brunt of the battle would realize that strike methods which involve riot and bloodshed are not the means whereby any good for labor may be attained. It may be contended that labor in the district under the new régime is enjoying better working conditions and wages; but these concessions were granted several months ago and cannot be attributed to the warlike methods which have since prevailed. There is little evidence of anything for the good of organized labor having been accomplished under Mr. Charles H. Moyer's leadership and the Western Federation of Miners' activities.

The effect upon some of the operating companies of the district is shown by the following table of the total receipts for the past two years of a number of the companies, which furnishes a true barometer of the state of industry.

| | Total receipts 1913. | Total receipts 1912. |
|----------------------------|-------------------------|-------------------------|
| Mass Consolidated | 189,557 | 349,374 |
| Quincy | 1,921,198 | 3,381,587 |
| Ahmeek | 1,433,695 | 2,757,576 |
| La Salle | 15,535 | 10,244 |
| Superior | 478,977 | 673,032 |
| Centennial | 247,120 | 285,075 |
| Isle Royale | 649,946 | 1,395,636 |
| Allouez | 650,205 | 918,435 |
| Winona | 419,235 | 541,128 |
| Tamarack | 643,566 | 1,300,238 |
| Osceola Consolidated | 1,774,810 | 3,071,818 |

It will be seen what a marked decline has taken place in bulk of the business of the copper companies; and to this must be added the greatly increased cost in production, which at the Ahmeek property was almost 100%, the total cost of refined copper in 1913 was 13.30c. per pound, while in 1912 it was 7.85c. While this figure is exceptional, a general increase in production costs is to be noted and deficits are by no means uncommon.

FRAMEWORK, COMPLETED MILL, AND LABORERS AT THE LA GRANDE PROPERTY.

Mill Building in the Andes

By ALFRED A. WATSON

The Collahuasi mining district is situated in the province of Tarapaca, Republic of Chile, S. A., a few miles from the boundary line of Bolivia. The ores of the district are principally copper, carrying a small amount of gold; some silver veins have also been discovered, but are not at present being exploited. The copper deposits cover a large area, extending over the top and sides of the Collahuasi mountain and the neighboring hills. They are principally owned and worked by two foreign companies, the Poderosa Mining Co., Ltd., owned by English interests, and the Collahuasi-La Grande owned by the Société Française des Mines de Cuivre. Collahuasi La Grande, a French company having its office at 43 Boulevard Hausmann, Paris, France. Up to now only the highest grade ore has been exploited and it is shipped abroad for treatment. Communications with the port of Antofogasta, Chile, distant 535 kilometres, is by means of the Ferrocarril de Antofogasta a Bolivia (Antofogasta-Bolivia R. R.) A branch line of 96 kilometres in length joins Collahuasi La Grande with the main line of this railway at Ollagüé, which is the end of the Chile division, the road from there being entirely in Bolivian territory.

Collahuasi La Grande lies in 21° south latitude and 68°40' west longitude and at Punto Alto, where all

the machinery was delivered, the rails are 4820 metres (15,814 feet) above sea level. A reference to the Ferrocarril de Antofogasta a Bolivia may be interesting as it is the only main artery of communication at present in operation from the Republic of Bolivia to the Pacific coast. The Arica-La Paz railroad, belonging to the Chilean government, for some reason has not been fully opened for traffic. The Bolivian railway does an immense business on a 2 ft. 6 in. gage. The passenger cars are roomy and comfortable, the sleeping and dining cars are excellent, while the freight cars are of 20,000 kg. (20 long tons) capacity each. The road at kilometres 116 to 170 inclusive runs through the rich nitrate fields of Antofogasta province and reaps a rich harvest from the transportation of nitrates to the coast and from machinery, timber, crude oil, and other supplies for the return journey.

At Calama, kilometre 239 and 2265 metres above sea level, the river Soa is crossed for the first time. The waters of this river are used for irrigation purposes, consequently an oasis is created, which is the only green spot encountered during the whole journey. Calama is the only important town on the Chilean division. At San Salvador, kilometre 254, a branch line 8 kilometres long connects with Chuquicamata, 2696 metres (8840 ft.) above sea. A large copper de-

YARETA, METHOD OF HAULING LUMBER, AND A GROUP OF LLAMAS.

posit is there being developed by the Chile Copper Company, a Guggenheim concern, which is erecting immense works for the treatment of the ore at the mines. The river Soa is again crossed by means of a steel viaduct at kilometre 298, near Cirochi. The rails are 102.4 metres (336 ft.) above the surface of the river; the bridge is of six spans of 80 ft. each and supported by steel towers. A branch line 20 kilometres runs from Conchi to Conchi Jezo, another important copper district.

San Pedro, at 312 kilometre and 3223 metres (10,700 ft.) altitude, is on a tributary of the river Soa. There, at the foot of the volcano San Pedro is the main reservoir for the storage of potable water which supplies all the requirements of the railroad, the nitrate plants, and also the city of Antofogasta, 193 miles distant. It is a good piece of engineering. The highest point on the main line of the railway is Ascotan, 360 kilometres (223 miles) from Antofogasta, the height above sea level being 3955 metres (12,859 ft.). From here the line runs on a slightly lower level right through into Bolivia, the height at Cebollan, 387 kilometres, being 12,200 feet.

Borax Lake

The run from Ascotan to Cebollar discloses a scene of matchless interest. The railroad skirts the shores of the celebrated borax lake of Cebollar, 24 miles long and several miles wide. The surface of the lake in certain seasons is pure white, like freshly fallen snow, varied by turquoise colored water in places. The old volcanoes on the border of the lake display the most wonderful colors, one especially showing vivid scarlet, reds, yellow, grey, and brown; a truly marvelous sight. The lake is the property of the Borax Consolidated, Limited and is said to be one of the largest natural deposits of borax known. At kilometre 435 and 3696 metres above sea level and two miles from the Bolivian boundary is situated Ollagué, which is the end of the Chilean division of the railway. It lies at the base of the isolated and imposing volcano of Allagué, 5872 metres (19,266 ft.) high. It is quite a feature of the landscape and emits constantly a plume of steam from near the summit. The Collahuasi branch line starts from Ollagué, and at kilometre 89 reaches Montt, which is on the Poderosa company's property. Six kilometres further is Punto Alto, which is one kilometre from Collahuasi La Grande, the terminus of the line.

Owing to the distance from the coast such heavy expense was incurred in shipping ores that it was possible to ship the highest grade of ore only; according to reports, ore containing less than 18% copper did not repay the cost of mining and freight. The La Grande company, however, determined to make an effort to avail itself of the enormous quantity of so-called low-grade ore which remained in the mines and on the dumps. With this object in view a 100-ton unit of a concentration plant was ordered after careful consideration as to location of the plant and the choosing of a convenient spot where sufficient water was to be

obtained, and where the ores from the various mines could be delivered at a reasonable cost by means of an overhead tramway of moderate length. Such a site was found at Capella, 14,650 ft. above sea level and near one of the Company workings, being some 6 kilometres distant from Punto Alto, where all machinery and material was delivered by the railroad company and transported from there to the mill site by mule carts and trollies. Accordingly timber and all other materials required were ordered from Antofogasta and rushed to the spot with all speed so that no delay should be caused by the winter snows. Grading was started on mill site and buildings for administration, *bodega*, *pulperia*, and dwellings for the workmen and their families were erected.

The country rock upon which the foundations were built was very friable in places and filled with fractures, necessitating heavy concrete retaining walls for the buildings. All machinery foundations, floors, and storage-tank were of concrete, the materials for which were carefully selected, the sand washed, and the aggregate graded. The best portland cement was used, and the most careful attention given to variations in temperature, so as to prevent the concrete from freezing, a very necessary precaution at that altitude. In all, some 720 cubic metres of concrete was used.

The concentration plant consisted of the following machinery, the ore being delivered at the receiving station by sub-aerial ropeway. One 6 by 10 ft. grizzly; one 60 ft. by 14 in. Robins conveyor; one 60 ft. by 36 in. Robins picking-belt conveyor; one 7 by 10 in. Blake crusher; one shaking tray feeder; two 24 ft. by 12 in. wet or dry crushing rolls; one 35 ft. by 8 in. Buckley elevator; one 84 by 48 in. revolving screen; one set of four 66 by 36 in. revolving trommels; one 24 by 12 in. crushing roll for re-crushing; one 40 ft. by 6 in. backed elevator; six 3-compartment 34 by 20 in. Hartz jigs, one 4-ft. Callow screen, one set of 3 hydrometric sizers, three No. 5 Wilfey tables, one 9-ft. pulp dewatering cone, and three 6-ft. vanners. The motive power was furnished by one 125-hp. Babcock & Wilcox water-tube boiler (another is being added) with water heater, boiler feed, pumps, etc. One 16 by 36 in. Corliss engine, one Bellis and Morecombe vertical duplex engine for driving, 50-hp. electrical generator, a general outfit for electric lighting, electric pumps, and motors for cableway, etc. The machinery was furnished by Fraser & Chalmers, Limited, London.

Mountain Sickness

A serious obstacle to carrying on work at such altitudes is the sickness and danger incurred by mountain sickness, called locally *puna* (poona) in Chile and *soroche* in Peru. It commences by difficulty in breathing, severe pains in the head, and vomiting, and the heart's action is terrific in intensity. Persons desiring to live there must be provided with sound lungs and a stout heart (in more ways than one) and good circulation of the blood. At first it is exhausting to make the slightest exertion and it requires from a few days to

a month or more to become acclimated. Frequently people have to be returned to a lower altitude without delay and some cases have a fatal termination. It is not to be wondered at that the natives from near the coast have the greatest dread of Collahuasi, the climate of which is probably aggravated by the fumes coming from some volcanoes that are situated at no great distance.

Climatic Conditions

The temperature is extremely variable. In winter the thermometer falls to 10°F. each night. During the daytime it occasionally rises to 45°, but usually only to 30°F. In any case immediately the sun gets low it drops below freezing. A sudden gust of wind will cause a drop of 15° at once. Snow lying on the ground makes the cold intense. Under such conditions it is difficult to secure the necessary intelligent workmen. The seasons in the southern latitudes are of course the reverse of the northern ones, midwinter down there being mid-summer north of the equator. In the Andes in summer it rains, the natives say, but what falls is hail and very severe storms they are, usually accompanied by terrific thunder and lightening. During the summer these cause little inconvenience but in the winter months heavy winds prevail, blowing sometimes with hurricane force, the snowstorms being of the regular western type, and the snow fine and dry. The cold is intense, the wind drifts the snow, all work has to be suspended, and all communication from outside is cut off for days. A curious thing about the snow in that region is that it gradually disappears without showing any signs of water around the edges. It simply seems to become less and less until it finally disappears. Another curiosity is that running water always freezes up in winter but the ground, which is loose and spongy, does not freeze below 3 or 4 inches.

Under these conditions the milling plant was erected. Ordinary labor is performed by Bolivian Indians, of which the women are the most conscientious workers. The Bolivians are tractable people, but the Chilenos are more intelligent, although harder to handle. All of the workmen are addicted to drink, which has to be guarded against, principally during their national *fiestas*. A better class of labor was obtainable at wages from 50 to 75% above the usual ones prevalent nearer the coast. In fact that was the only inducement for men to remain on the work for a limited time. The wages paid were, boss carpenter 25 pesos,* concrete boss 20 pesos, boss machinist 20 pesos, boss electrician 16 pesos, boss blacksmith 16 pesos, carpenters 14 to 17 pesos. Ordinary mechanics and blacksmiths 14 pesos, concrete mixers 11 pesos, common labor from 6 to 10 pesos per day. The timber, from Puget Sound, and costing delivered at Punto Alto 135 pesos per M., was rough sawed and framed on the spot by native carpenters, not one of whom had had any previous experience in mill construction. When the frames of the building

were raised the workmen refused to go aloft. In fact, at times the cold was so intense and the wind so strong that it was impossible to go aloft and finally when the galvanized iron covering had to be put on it was necessary to put on the sides first and the roof afterwards, otherwise it would have certainly been carried away by the wind. Fortunately the entire buildings were successfully covered in previous to the beginning of the winter snows. The buildings were built on terraces on a side hill in the usual manner, which exposed them to the terrific winds which came up the valley. For this reason, combined with necessity of providing against damage from earthquake, a thorough system of bracing had to be executed, providing against such emergencies. The erection of machinery under cover was a simple matter in comparison.

Fuel

The fuel used in that region is *yareta* (*Azorilla madreporica* or *Azorilla glebaria*) a sort of moss containing much resin which when dry burns rapidly with good heat and leaves an abundant white ash. Compared with steam coal, 2.7 tons of *yareta* is equal in calorific power to 1 ton of coal. It is found within a zone between 12,000 and 15,000 ft. altitudes and is supplied by contract by Bolivian Indians who bring it to the mines on llamas. Each of these animals is supposed to carry a load of 80 lb. They are useful and interesting beasts and it is said that no one except a Bolivian Indian can manage them. Presumably this is so, judging from the manner in which they stampede when alarmed.

All supplies and material of whatever description at Collahuasi have to be brought up from the coast, the surrounding country being bare and absolutely barren desert, not a single tree or shrub visible. A few tufts of *puna* grass are sparsely scattered over the ground; in the valleys grass is a little more abundant and furnishes food for the llamas for a short time. The wild animals are few. A few troops of vicunas roam the lower large valleys. A fox is occasionally seen, the South American ostriches (*rhea*) run in small batches, chinchillas and viceachas are common. The latter is a small rodent related to the chinchilla, with a head that looks like a cat's, but a rat-like tail. A small rat and a species of partridges are the only other animals to be seen. A curious fact, illustrating that work at high altitudes has advantages as well as disadvantages, is that there are no vermin to be found outside of stable. There are no flies, fleas, bugs, or mosquitoes at any time of the year.

The two headings of the Mount Royal tunnel at Montreal, met on December 10. It took 15 months and 4 days to drive the 8 by 12 and 10 by 12-ft. headings a distance of 3¼ miles through a great variety of rock.

Overburden stripped at the Nevada Consolidated copper mine, during the last quarter of 1913, totaled 982,689 cubic yards. The cost was \$308,519, or 31.4c. per yard.

*The Chilean peso fluctuates in value, but may be roughly taken at 18½c.

Third Beach Line at Nome, Alaska

By ARTHUR GIBSON

The auriferous gravel deposit or pay-streak, known as the 'Third Beach Line', running on a true course of N. 63° 39' W., with a magnetic variation ranging from 18 to 20° E., situated about three miles north of Nome on Seward Peninsula, Alaska, and extending for a distance of 5.1 miles, is no doubt one of the greatest freaks of nature discovered in the present age.

The original discovery of the beach line was made by Sam Samson, now residing at Stevenson, Washington, who started to sink a shaft on the Cyrus Noble placer claim (shown on the map opposite, directly east of No. 4 above Discovery on Bourbon creek) in November 1901. Being a poor man and without the

pay-streak, which was 60 ft. wide, December 24, 1905. The news of Mr. Samson's discovery did not become public until in January 1906, after which all available thawing plants were placed in commission and the pay-streak of the Third Beach Line was definitely traced and located for its entire length of five miles, before the opening of navigation in Bering Sea, five months later.

The present surface of the ground shows no indications of water action. It is uneven and the depth from the surface to the pay-streak varies from 20 to 124 ft. The surface ground consists principally of glacial silt or 'muck,' averaging six to ten feet in depth.

PROFILE OF THE BEDROCK ALONG THE PAY STREAK

necessary funds to procure a steam thawing plant and fuel, he had to adopt the extremely slow process of thawing the perpetually frozen ground by burning willows in the bottom of the shaft, reaching bedrock at a depth of 95 ft. in May 1902, after six months of hard work. The gold discovered in this shaft was very fine flour gold in a layer of ruby and black sand about one and one-half inches thick, eight feet above bedrock. Being without funds and unable to interest anyone of means, Mr. Samson had temporarily to abandon this work about August 1, 1902.

J. C. Brown commenced prospecting his placer claim, No. 1 below Discovery, on Little creek (at the extreme westerly end of the Third Beach Line and about 1¾ miles west of the Cyrus Noble claim) in August 1904, and on September 19, 1904, he discovered a very rich pay-streak in the northeasterly portion of his claim, which upon investigation proved to be a beach formation.

During the spring of 1905 the same rich pay-streak in similar formation was traced and discovered by laymen on the adjoining claim toward the east, known as the 'Portland Bench.'

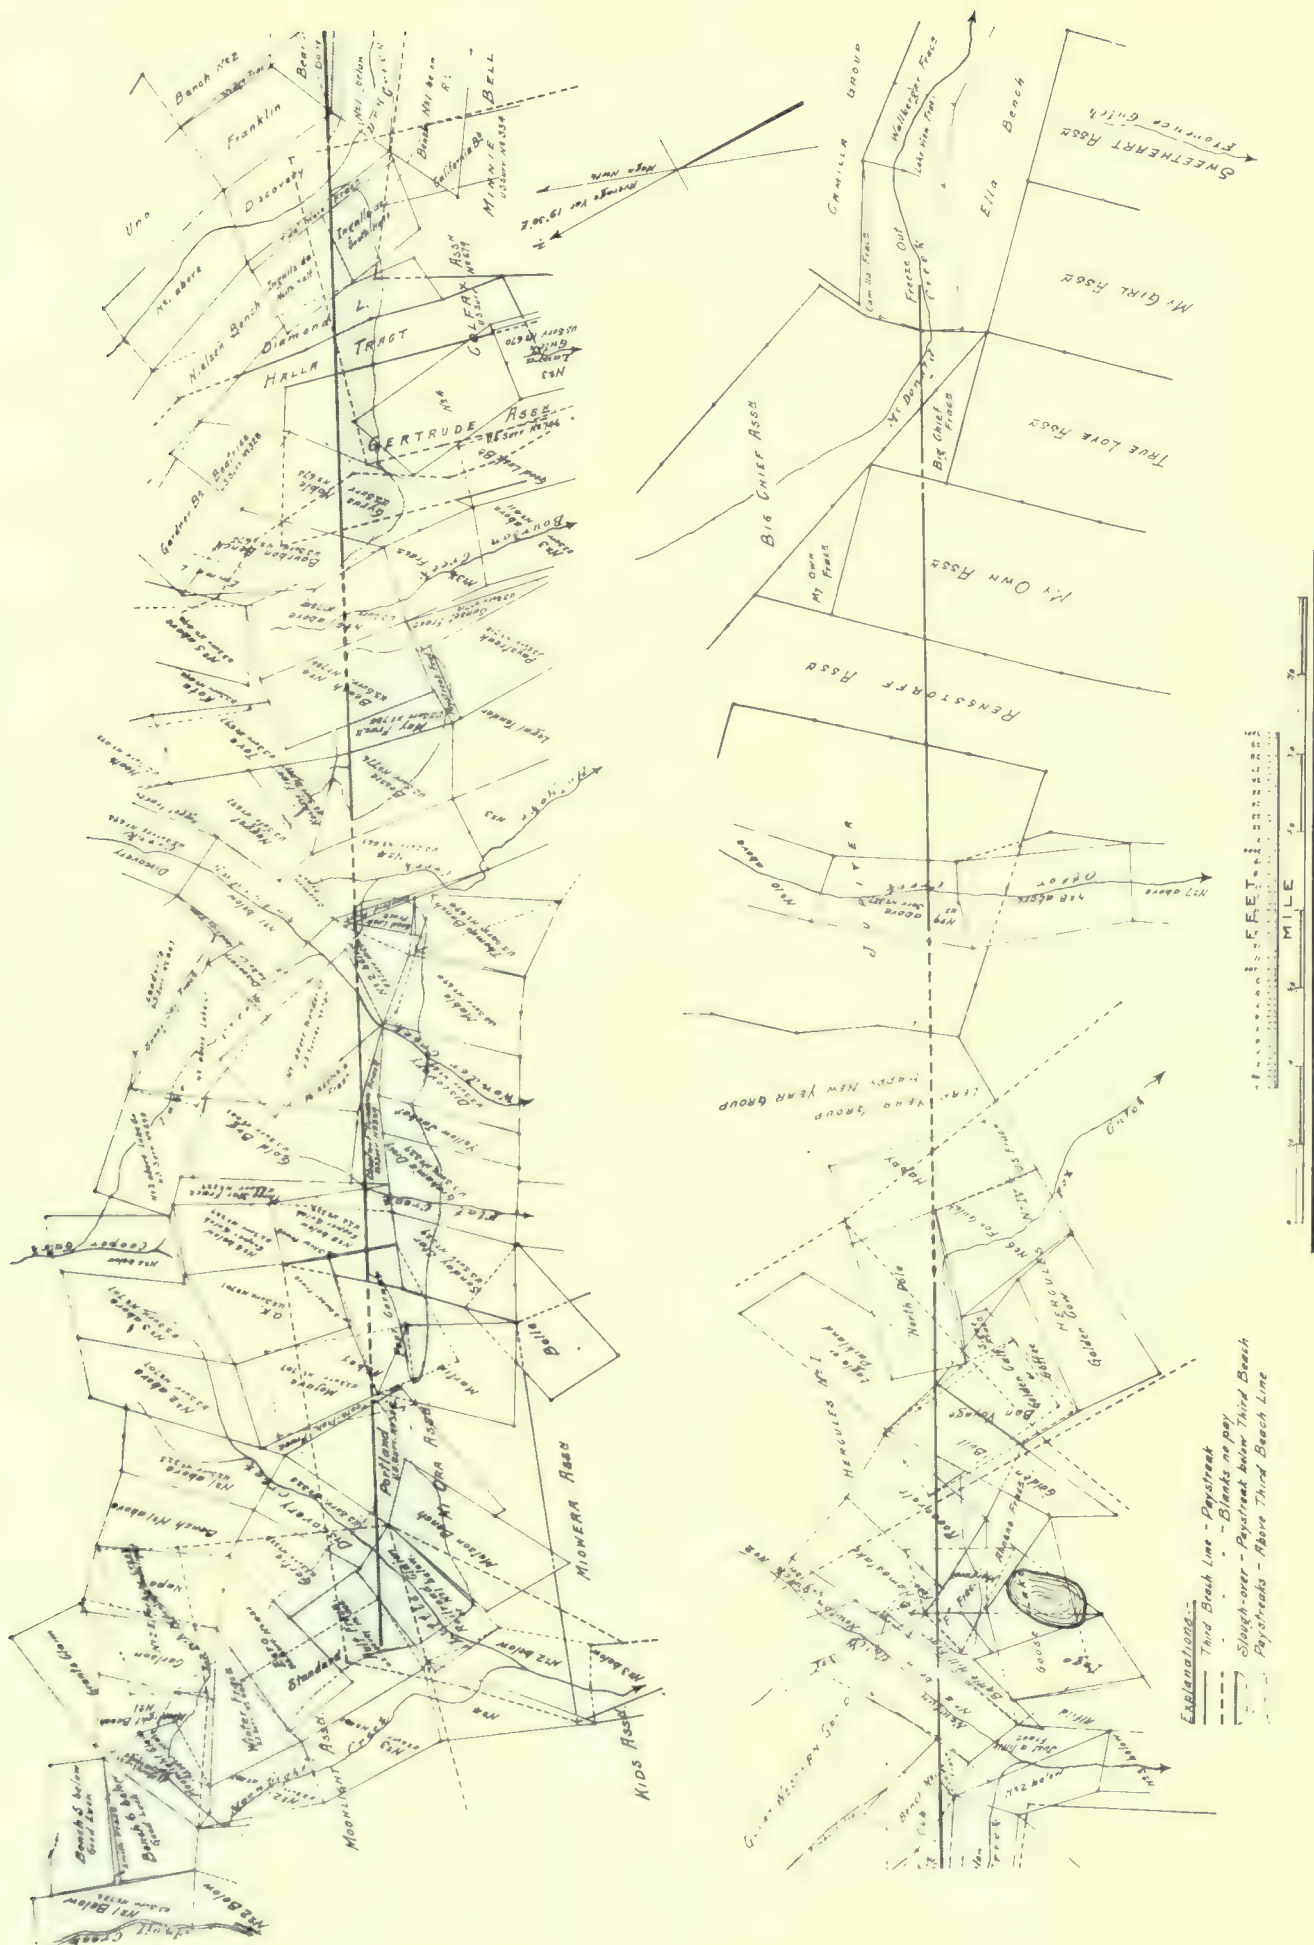

Mr. Samson by this time succeeded in raising the necessary funds to secure a steam thawing plant and fuel to thaw out his old shaft, which had filled with surface water and frozen solid. He commenced this work November 1, 1905, and after searching bedrock he drifted northerly 22 ft., where he tapped the pay-streak of the Third Beach Line on December 6, 1905. He continued driving northward and cross-cut the

Although in a few instances the gravel comes to the surface, the ground between the glacial deposit and the pay-streak was as a general rule composed of gravel and sand; in a few places intersected with streaks of clay and quicksand.

The Pay-Streak

The heavy line on the map indicates the pay-streak of the Third Beach Line: where the same line is fulldrawn the pay-streak was found intact, that is, had never been disturbed and showed distinctly the original stratification of the ancient beach dipping toward the sea. Here the overlying ground was always found frozen all the way from the surface to the bedrock, independent of depth. Where the heavy line is dotted, the original pay-streak had been washed out of place by the action of water channels. In such places gold was scattered over a large area in layers on bedrock too thin to be recovered at a profit. In addition, the overlying ground was in these cases thawed and water-logged, requiring heavy timbers to prevent caving and large pumps to keep the workings dry, thereby increasing the operating expenses beyond profitable limits. Only one exception to this rule occurs, that is, so far as the thawed ground is concerned: on the Four Corner placer claim, where the old water-channel has ceased running and the ground from the surface to bedrock has frozen after washing out and scattering the pay-streak.

The figure above shows a profile of the bedrock along the pay-streak of the Third Beach Line, which indi-

cates terraces worn down by the action of the waves. The main pay-streak is shown at A and B; A shows the heaviest concentration containing the most gold; B the leaner part; and C and D indicate the 'slough-over' or finer gold carried down by the concentrating action of the waves. The drop-offs on the terraces were about 4 ft. high, and the flats, ranging from 80 to 200 ft. in width, had a grade of about 2 ft. in the entire width.

Bedrock at the lower rim of the main pay-streak, as indicated on the above sketch, was always 78.6 ft. above the present mean sea-level in Bering Sea, independent of what material the bedrock consisted, whether true rock formation or clay, the latter known as false bedrock. True bedrock consisted mostly of schist, intersected with quartz stringers, rarely containing any gold; limestone and black slate occurred in a few places. False bedrock consisted of clay or clay and sand mixed.

The material making up the main pay-streak was principally composed of well washed and rounded quartz pebbles in size from sand to pebbles of 2 to 3 in. diameter. The mineral concentrations contained besides gold a great deal of black sand and pyrite and various other minerals in smaller quantities. With very few exceptions all gold extracted had to be amalgamated, in order to save the fine gold and more readily separate it from the heavy iron sand.

Peculiarities of the Pay-Streak

The peculiarities of this pay-streak were: (1) its general course was a perfectly straight line from one end to the other, although its width ranged from 25 to 60 or 70 ft., and in one or two instances as much as 200 ft.; (2) its lower rim elevation above present mean sea-level in Bering Sea was always 78.6 ft. along its entire length; and (3) wherever the ancient beach was found intact and in place it was never found lacking in gold, and the overlying ground was always frozen independent of depth. The question of how 100 ft. or more of gravel could be deposited on top of this ancient beach without disturbing its original stratification in the least, will ever remain a mystery.

The greatest thickness of the main pay-streak averaged from 18 in. to 2 ft. In one or two cases it was as much as 6 ft., but only for a short distance. The 'slough-over' pay-streak, indicated by shaded areas on the map, seldom exceeded 14 inches in depth and contained only gravel of low grade.

The main pay-streak contained exceedingly rich gravel in certain parts. Pans yielding as high as \$500 were not uncommon on a few claims. On one particular claim the pay-streak averaged 35 ft. in width and 18 inches in depth, of which 110 lineal feet produced over \$360,000; or more than \$3000 per lineal foot; approximately \$1500 per cubic yard. The total production of the entire pay-streak of the Third Beach Line including the 'slough-over,' based on avail-

able data, is a little over \$10,000,000; or an average of \$400 per lineal foot of the entire pay-streak, approximately \$500 per lineal foot of the pay-streak in place and actually mined.

With very few exceptions, all gold produced by claims on the Third Beach Line was very fine, particularly in the extreme eastern portion around Otter and McDonald creeks, where it was flour gold that could only be saved by amalgamation. The fineness averaged 900 in the western portion, 888 in the central portion, and 906 in the eastern portion of the pay-streak.

Millwork at the Brunswick Consolidated Mine

During 1913 the 20-stamp mill of this property at Grass Valley, California, crushed 15,334 tons of ore, with the following details:

| | |
|--|---------|
| Duty per stamp per 24 hours, tons..... | 2,364 |
| Quicksilver fed to batteries, ounces..... | 11,713 |
| Amalgam recovered, ounces | 28,204 |
| Bullion produced, ounces | 11,461 |
| Concentrate produced, tons | 269 |
| Pyrite in ore, per cent..... | 1.75 |
| Average value per ton..... | \$56.00 |
| Cost of freight and treatment of concentrate, per ton of concentrate | 15.97 |
| Cost per ton of ore milled | 0.28 |
| Cost of crushing and concentrating ore, per ton..... | 0.79 |
| Bullion charges, per ton | 0.044 |
| Total mill costs | 1.071 |
| Value of ore before milling, per ton | 13.92 |
| Recovery by amalgamation and concentration | 13.58 |
| Recovery, per cent | 97.60 |

The ore is crushed through a No. 0 punched tin screen equal to about 45-mesh wire screen, which accounts for the low duty per stamp but excellent recovery of gold.

Water Consumption at Kalgoorlie Mines

During October 1913, 11 mines, comprising the Kalgoorlie & Boulder Mines Water Trust, purchased 35,655,000 gal. of water from the Western Australian Government at \$1.68 per 1000 gal., as follows:

| Ore treated, tons. | Process. | Water used, gallons. |
|---------------------------------|----------|----------------------|
| Associated | Dry | 3,139,000 |
| Associated Northern | Dry | 1,293,000 |
| Chaffers | | 214,000 |
| Golden Horse-Shoe | Wet | 5,327,000 |
| Great Boulder Perseverance..... | Dry | 2,246,000 |
| Great Boulder Proprietary.... | Dry | 5,742,000 |
| Ivanhoe | Wet | 3,650,000 |
| Kalgurli | Dry | 2,772,000 |
| Lake View & Star..... | Wet | 5,391,000 |
| Oroya Links | Wet | 3,494,000 |
| South Kalgurli | Dry | 2,387,000 |

All of these mines are equipped with high-class steam boilers, engines, and water-saving appliances.

Fire damaged the power-plant of the Mt. Morgan mine, Queensland, during December, necessitating a shut-down for several days.

Application of Three-Phase Motors to Winding Engines and Hoists

By C. ANTONY ABLETT and H. M. LYONS

*A three-phase motor cannot be built for a very low speed without its power factor being bad, which tends to upset the regulation of the supply system, and for this reason where three-phase motors are driving winding engines they nearly always run at higher speeds than the drums, and are geared to them. In the Ward Leonard or Ilgner system, however, where a direct-current motor is used, this is almost invariably direct coupled to the drum.

The speed of a three-phase motor is controlled by varying the resistance in the rotor circuit so that all three-phase winding engine motors are naturally slip-ring motors, while the direction of rotation is reversed by interchanging two of the connections to the stator, so that a reversing switch must be provided for this purpose. The main control lever for a small three-phase winder does not move backward and forward in a quadrant with a straight-line motion, but the quadrant has two parallel slots connected by a cross-slot. When the main control lever is moved along the cross-slot it operates the oil switch and reverses the motor. When it is moved along one of the parallel slots it speeds up the winding engine in one direction, when it is moved along the other slot the winding engine speeds up in the other direction. With larger winders the reversing switch is operated electrically, and the control lever moves backward and forward in a straight slot in a quadrant. The winding engine is at rest when the lever is in the middle position and as the lever passes through the middle position it makes an electrical contact which actuates the reversing switch.

The Three-Phase Induction Motor.

In order to explain the differences between the control of a three-phase winder and that of a Ward Leonard winder, it is necessary to refer briefly to the behavior of a three-phase induction motor when resistances are connected in the rotor circuit. When the stator of a three-phase motor is connected to the power circuit, and the rotor revolves, a voltage is produced in the rotor proportional to the difference between the synchronous speed and that at which the rotor is rotating, and this voltage causes a current to flow in the rotor which produces the turning moment. If a resistance is connected in the rotor circuit, there will be a certain drop in pressure across it proportional to the current in the rotor and to the value of the resistance and, consequently, the rotor must fall in speed to provide sufficient voltage to overcome this drop in pressure, so that the current and

turning moment which the motor is giving is maintained. If the amount of resistance is increased the motor will naturally drop more in speed. If the motor is required to give a less turning moment, requiring a reduced current in the rotor, the drop in pressure across the resistance becomes less and the motor will speed up until the balance between the rotor voltage and the drop in pressure is restored, until finally at light load the speed of the motor will approximate to the synchronous speed. Thus, if the proper resistances in the rotor circuit of a three-phase induction motor are connected to reduce the speed by a given amount for a definite turning moment, the speed of the motor will increase if the turning moment which it has to give decreases, and it will decrease if the turning moment increases.

Control of Speed

It will thus be seen that while with a Ward Leonard or Ilgner winder, the winder runs at a definite speed for each position of the control lever, and the speed of the winder is independent of the load in the cages, with a three-phase winder the speed does not solely depend on the position of the control lever, but also depends on the turning moment which the motor has to give, so that for a definite position of the control lever the speed may vary according to the position of the cages in the shaft and according to the load that is being hoisted, for as the loaded cage is being hoisted, its weight becomes more and more balanced by the weight of the rope attached to the empty cage.

With the three-phase winder, therefore, the manipulation of the levers would be different as different loads are being hoisted, and it is therefore impossible to employ cams on the depth indicator to limit the acceleration and to bring the loaded cage to a slow speed by the time it reaches the bank. In the three-phase winder, therefore, is a return to the case of a steam-engine where the wind is entirely in the hands of the driver and reliance must be placed in his skill for the safe handling of the plant.

Where the speed of a three-phase induction motor is controlled by placing resistances in the rotor circuit, and the motor is giving a definite turning moment, the same amount of power will be taken from the supply system whatever the speed of the motor may be. The turning moment multiplied by the speed gives the amount of power which the motor uses and the remainder of the power is wasted in the resistances. Thus the three-phase motor involves great waste of power.

Fig. 1 is a power diagram for a three-phase winder with a cylindrical drum winding at the rate of 270 tons per hour from a shaft 1600 ft. deep, the maximum

*From a paper on 'Electrical Driving of Winding Engines and Rolling Mills' read before the Canadian Society of Civil Engineers and the Canadian Mining Institute.

speed being 40 ft. per second. The shaded portions of this diagram represent the power which is wasted in the resistances of the starter in starting and stopping the motor, and in this particular case the useful

be more than the energy wasted in starting and stopping the three-phase winder.

Advantages of Three-Phase Winder

The three-phase winder is advantageous:

- (1) Where the capital cost of the plant is a prime consideration, as the total cost of the three-phase winder is from 20 to 35% lower than that of a Ward Leonard winder.
- (2) Where the starting and stopping is infrequent and long runs at full speed are required, as is particularly the case with slope haulage.
- (3) Where the winder is working intermittently, when, if a Ward Leonard set were installed it would have to run for long periods without doing any work.

The three-phase winder is disadvantageous:

- (1) For vertical shafts, as it cannot be fitted with the safety appliances used with the Ward Leonard winder.
- (2) Where the winds are short and the winding speed is high; that is, large outputs.
- (3) Where the power station from which the winder is supplied is relatively small, because in the case of a three-phase winder the load comes on instantaneously, and not gradually as with the Ward Leonard winder, so that the three-phase winder would disturb the regulation of the electrical supply system.
- (4) Where there is a long transmission line between the power station and the winder, and the fluctuations in demand of a three-phase winder would cause considerable variation in voltage. This would not only have a bad effect on other plant supplied in the same circuit, but would have an adverse effect on the three-phase winder itself, because the turning moment which a three-phase motor can exert is proportional to the square of the voltage, so that a small drop in voltage could greatly reduce the turning moment which a three-phase motor could give, and in bad cases it might even be found difficult or impossible to start the winder until the regulation of the system was restored.

There are three methods by which the load can be lowered with a three-phase winder: (1) by controlling the speed with the mechanical brakes; (2) by lowering at such a speed that the motor is run above its synchronous speed and so acts as a generator and returns power to the supply system; (3) by reversing the connections to the motor so that it is giving its turning moment in the reverse direction to the rotation, and controlling the speed by the use of the ordinary control lever with reverse current.

The first of these methods is objectionable, as it produces a large amount of wear and tear on the brakes, and it is difficult to design the brake paths

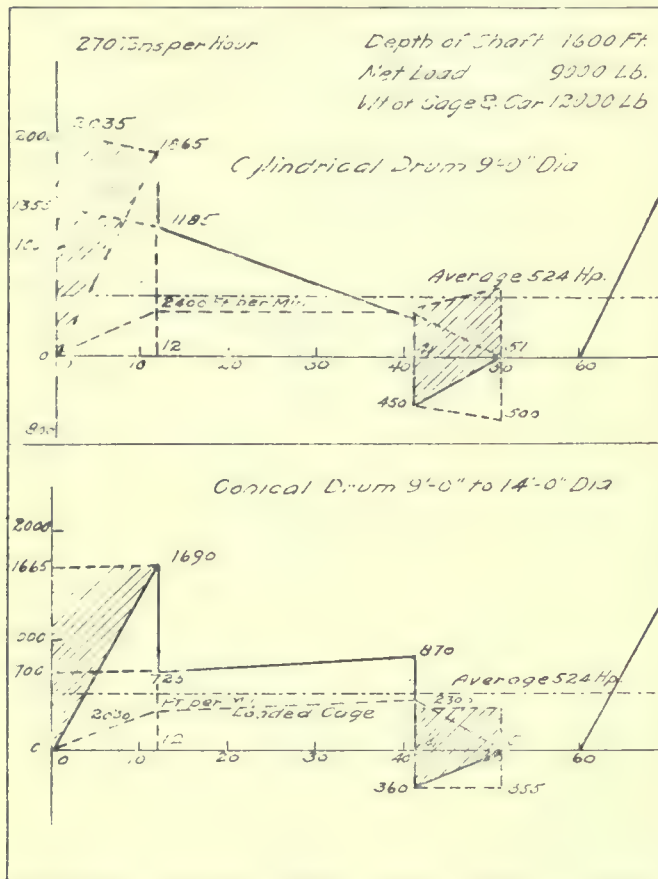

FIG. 1.

work done by the winder is 524 hp. minutes per wind. The amount of energy wasted in the starter is 325 hp. minutes per wind. Taking into account the efficiency of the three-phase motor, the energy taken by the winder from the supply system is 910 hp. minutes per wind. The average efficiency of the electrical plant, therefore, is only 57.5%. Fig. 1 shows how large the power losses are in starting and stopping a three-phase winder. It also illustrates a case that is much more suitable for a Ward Leonard or Ilgner winder than a three-phase winder, and as the loss in starting and stopping a three-phase winder is very great, it will be seen that it is most advantageous to employ a three-phase winder where the starting and stopping is infrequent, and where there is a long run at full speed, when the three-phase winder is economical, or where there is a considerable interval between winds. These are practically the conditions of a long slope haulage.

Under such conditions a three-phase winder can easily prove more economical in power than the Ilgner or the Ward Leonard winder, because, with the latter, the motor generator set would have to be kept running continuously and this involves an unceasing though small expenditure of power, so that the energy taken to run the motor generator set can easily

so that the heat generated is dissipated and burning of the brake blocks is prevented.

The second method is economical in power, but it is difficult to control because the electrical braking action does not take effect until the speed of the motor has exceeded synchronous speed. The motor must first be switched on in the lowering direction when the motor power is increasing the acceleration due to gravity, and in some cases to prevent this acceleration being too great the speed has to be checked with the mechanical brake. As soon as the motor exceeds synchronous speed the electrical brake will take effect and the speed of the motor will increase until it is four or five per cent above synchronous speed, which is higher, of course, than the ordinary hoisting speed, and the motor will remain practically steady at this speed and act as an induction generator, returning power to the line. It is not possible to use this generating effect to bring the cage to rest, but the lever may be brought back past the mid-position so that the cage is brought to rest by giving the motor the reverse current, but while the lever is being moved over there is no electrical braking effect whatever, and to prevent the cage increasing in speed it has to be checked with the mechanical brake. It will thus be seen that this method of control is distinctly difficult and should only be used in the case of long winds, such as slope haulage, where there is plenty of time to execute these manoeuvres.

The third method by which the connections of the motor are reversed, so that it is exerting its torque against the rotation, is extremely wasteful, because the motor takes power from the line in proportion to the turning moment which it is exerting, as well as the power which is given out by the winder, corresponding to the work done by the loads in descending.

As an example of this, attention may be called to the lowering diagram, with reverse current, shown in the figure. The amount of energy given up by the lowering of the load is 20,900 hp. seconds. The amount of energy taken by the motor from the supply is 42,900 hp. seconds. Therefore, in order to exert the braking effect on the winder, and to absorb the power given up in lowering the load, which amounts to 20,900 hp. seconds, the starter has to dissipate 63,800 hp. seconds. It will easily be seen, therefore, that when a load is lowered in this manner the amount of energy which the starter has to dissipate is very large, and in order to enable lowering to be carried out in this way it would, in many cases, be necessary to employ a much larger starter than is required for controlling the winding engine when hoisting. This method of lowering is the easiest to control, and for this reason, although it is very wasteful, it is generally adopted for large three-phase wind-

Starter and Controlling Resistances

From what has been stated above it will be seen that for the control of large three-phase winding en-

gines, resistances have to be provided which will dissipate a considerable amount of power. In the case illustrated in Fig. 2, 325 hp. will have to be dissipated

FIG. 2.

continuously, and means have to be adopted for absorbing this power in the controlling resistance and carrying away the resultant heat developed, while, at the same time, the controlling resistance is of a form which can be easily operated by the driver.

A very usual type of controlling resistance is a liquid resistance and consists of two tanks arranged vertically one above the other, in the upper tank of which are fixed the electrodes which are connected to the sliprings of the three-phase motor. When the winder is at a standstill the liquid is practically all contained in the lower tank, but is being continuously pumped into the upper tank by means of a small motor-driven pump, from which it flows back into the lower tank over a movable weir. In starting the winder the switch in the stator circuit is first closed by the control lever, and then, as the control lever is moved over, this weir is gradually raised, thereby raising the level of the liquid round the electrodes in the upper tank and reducing the resistance in the rotor circuit. This enables a very large controlling resistance to be operated easily by the driver without the complication of electrical auxiliary gear, etc. The liquid in the lower tank is cooled by means of water circulating through a coil of pipes, which forms a ready way of carrying away the heat generated in this tank.

Emergency Gear

A three-phase winding engine is provided with a mechanical brake, which is brought into action by means of a weight attached to a lever, but the brake is normally held away from the brake drum by air pressure. If this air pressure fails, then the weight brings the brake on to the brake drum and stops the winder. As the speed of a three-phase winder for a given position of the control lever depends on the load which is being hoisted, it is not possible to provide cams on the depth indicator in order to slow down the cage before it reaches the bank. The proper slowing down of the cage depends on the skill of the driver, but an over-wind device is fitted both in the shaft and on the depth indicator, and in case the cage over-runs the bank it cuts off the power from the motor and applies the brake by means of the emergency gear. An emergency lever is provided on the driver's platform by which he can cut off the power and apply the brake, stopping the winder immediately in case of necessity. In case the power supply fails the brake is at once applied through the emergency gear.

With the three-phase winder the speed for hoisting men cannot be limited automatically, as in the case of a Ward Leonard winder, and the speed depends entirely on the skill of the driver.

For shaft and rope inspection the slow speed is obtained by leaving a very large amount of resistance in the rotor circuit of the motor, but as the speed at which the winder runs for a given position of the control lever depends on the turning moment which is being exerted, and as the turning moment varies continually from the commencement of the wind, owing to the adjustment of balance produced as one rope is wound on and the other rope is wound off, the speed can only be maintained constant by the driver continually adjusting the position of the control lever and the winder cannot, as in the case of the Ward Leonard system, be left alone to maintain the speed at which it has once been set. These slow speeds are the cause of considerable waste of power in the controlling resistances and may require that additional large controlling resistances should be installed in order that slow speed runs may be made, which if frequently made will materially reduce the overall economy of the three-phase winder.

Three-Phase Commutator Motors

The three-phase commutator motor has somewhat similar characteristics to those of a direct current series motor, that is, it develops a large turning moment at the moment of starting, and as the load decreases the speed rises until at no load the motor will attain a dangerous speed unless it is properly controlled. The motor has a large overload capacity and does not stop even under very heavy overloads but only slows down. The speed of a three-phase commutator motor can be closely regulated, within wide limits, by shifting the brushes on the commutator, and

the efficiency and the power factor are high throughout the whole range of speed regulation. A mechanical device can be fitted to the motor which by shifting the brushes prevents the speed rising above a determined value, however small the load may be.

A powerful and easily regulated braking effect can be obtained electrically by moving the brushes back through the neutral position, and when braking in this manner, especially when lowering loads, the motor acts as a generator and will return about 70% of the mechanical energy to the line as electrical energy. The direction of the rotation of the motor can be reversed by moving the brushes to the other side of the neutral position, but it is desirable at the same time to reverse the stator current in order to prevent sparking at the commutator. The stator can be constructed for any reasonable line voltage, but as the commutator can only be made for comparatively low voltages, it is usually necessary to install a transformer between the stator and the commutator. There are constructional reasons which make it difficult to build very slow speed three-phase commutator motors, so that such a commutator motor is usually geared to the winding mechanism.

Arrangement of Winder and Motor

The arrangement of a winder with a three-phase commutator motor is very simple. The winder is controlled by a single lever which shifts the brushes on the commutator and operates the change-over switch. The commutator motor shares with the three-phase induction motor the disadvantage that for a definite position of the control lever its speed depends on the load in the cage, consequently, the safety devices employed with such a motor are very similar to those used with a three-phase induction motor, and protection is afforded by the release of the emergency brake and the interruption of the supply circuit in case the motor or winder is overloaded, or in any other contingency. The three-phase commutator motor possesses the great advantage over the induction motor that its power factor at full load is about unity and the power factor maintains its high value practically for the whole range of speed regulation, so that the conditions for the electrical supply circuit are very favorable.

The actual full load efficiency of the three-phase commutator motor is about 5% less than that of the corresponding induction motor, but the commutator motor can be started and its speed can be regulated without loss of power, and during braking periods or periods of lowering a load, 70% of the mechanical energy can be returned to the supply system as electrical energy, so that the total efficiency of a winder driven by a three-phase commutator motor can be better than that of a corresponding winder driven by a three-phase induction motor.

As a winder driven by a three-phase commutator motor can be started without loss of power, the power taken by such a motor rises gradually from the

moment of starting to the end of the acceleration period, so that there is sufficient time to enable the generators in the power house to follow the load fluctuations. Such winders, therefore, can conveniently be supplied with current from comparatively small power stations provided that the generating sets are fitted with modern voltage regulators.

The capital cost of a winder provided with a three-phase commutator motor is higher than that of a winder provided with a three-phase induction motor.

The following are some particulars of the largest winders fitted with a three-phase commutator motor which have come to the authors' knowledge:

Depth of wind 1,650 ft.
Weight of load 7,000 ft.
Maximum winding speed 1,575 ft. per minute
Output 94 tons per hour

This winding engine is driven by two 310-hp. three-phase commutator motors, having a synchronous speed of 300 revolutions and a maximum speed of 370 revolutions. This winding engine is supplied from a three-phase, 25-cycle, 500-volt circuit. The authors have no data available regarding the power consumption of this winding engine. A smaller winding engine driven by a three-phase commutator motor gives an average power consumption of 1.4 kilowatt hours per shaft horse-power, which compares very favorably with other electrical systems of winding.

The Zinc Corporation, operating a mine, mill, and a flotation plant at Broken Hill, New South Wales, will double the capacity of its lead mill at a cost of \$248,000. It is intended to construct the plant so that it will be possible to change the process from the treatment of lead ore to the treatment of zinc ore, or vice versa. At present, the Lyster process, a modification of the flotation process, is treating 100 tons of slime per day hitherto thrown away, slime from the treatment of the lead ore as it comes from the mill, high grade and mixed with lead concentrate. The Corporation is now securing nearly 90% of the original lead content of the ore in the form of a high-grade lead concentrate, 7% of the recovery being due to the Lyster process, which costs 96c. per ton of material treated. The Horwood process is being applied to a certain by-product from the zinc concentrator, the said product being in effect a mixed zinc-lead concentrate. This residue is subjected to a slight roast, and upon being treated by flotation it yields, on the one hand, a fine zinc concentrate, and on the other a good lead concentrate. The application of the Horwood process, in respect of the Zinc Corporation's visible supplies of ore and concentrate, represents very nearly one whole year's production of zinc concentrate; the lead is not quite so much.

Lessees at the Standard mine, Bodie, California, covered 282 ft. of development last year, producing 229 tons of ore, paying a royalty of \$16.55 per ton.

Natural Resources Survey of New Mexico

The Natural Resources Survey of the state of New Mexico dates from 1900, and while no funds have been appropriated at the last two legislative sessions, the geological division is still active and doing valuable work.

The act for the establishment of a conservation commission and a natural resources survey provides that three persons, no two from the same judicial district, shall be appointed by the Governor for terms of one, two, and three years, and that reappointees shall hold for three years each. The Governor and the director of the survey, who is the state geologist, are also members of the conservation commission. The chief duties of the commission are to make an inventory of the state's resources and provide for their conservation through conferences with the federal commission and remedial legislation.

The specific objects of the survey are: (1) the study of the structural and economic geology, with special reference to the value and accessibility of the various products for mining and manufacturing purposes. (2) The physical and chemical analyses of soils. (3) The collection of climatological data. (4) The establishment of topographical control with complete survey of irrigation areas. (5) The study of surface and ground water resources. (6) The collection of biological data. (7) The making of such other researches as the board may direct. (8) The dissemination of this information by publication, correspondence, and addresses. (9) The coöperation with the U. S. Geological Survey, Department of Agriculture, Forestry Service, and other federal bureaus wherever benefit may accrue to the state. The head of the geological department of the state university holds the position of state geologist and is director of the resources survey and chief of the division of geology. The divisions of agriculture and mining engineering are controlled by the respective colleges in the state, while the division of water resources and irrigation is in charge of the state engineer. The director and chiefs of divisions constitute the staff of the survey.

Expeditions were made and a brief report printed out of the original fund of \$1500 which was appropriated for the expenses of the commission for the years of 1909 and 1910, but the limited issue is now exhausted. No other report has since been made, but the Governor has renewed the personnel of the commission, who are serving without remuneration.

The state geological survey is coöperating with the U. S. Geological Survey in the collection of non-metallic mineral statistics of the state. It is also occupied from time to time in the classification and valuation of mineral land for county taxes, and in the inspection of deposits on grant lands and elsewhere when the results are more or less of a public benefit. Expenses in these instances are paid by those desiring the services.

Razing the Steptoe Valley Stack

By D. BOYD-SMITH, Jr.

THE STACK (ON THE RIGHT) BEFORE RAZING.

with an inside diameter of 18 ft., the thickness of the walls varying from 13 in. at the top to 50 in. at the bottom as is shown in Table I.

TABLE I

| | | | |
|--|--------|-----------------|--------|
| From base up 40 ft. 30 to 50 in. due to octagonal shape. | | | |
| Next 10 ft..... | 27 in. | Next 10 ft..... | 19 in. |
| " 10 ft..... | 25 in. | " 40 ft..... | 17 in. |
| " 10 ft..... | 23 in. | " 60 ft..... | 15 in. |
| " 10 ft..... | 21 in. | " 60 ft..... | 13 in. |

At the time of its destruction the stack had been eaten away until it was only 190 ft. high with a thickness of approximately 10 in. at the top, and it is quite logical to expect that the same amount of decrepitation had taken place on the inside throughout its entire height. On the south side of the stack and 20 ft. above the concrete foundation, there was an opening 10 ft. wide and 15 ft. high, from the top of which started a series of cracks ranging from 10 to 50 ft. in length and extending to the top. The north and east sides were in approximately the same condition. The west side, however, showed a consid-

TELESCOPING EFFECT PRODUCED BY THE EXPLOSION.

For the past two years the stack for the roaster building of the McGill plant has been in very bad condition due to the action of the acid in the smoke. This action has continued slowly but none the less surely for some time past, and through its eating effect on the brick had caused parts of the stack to fall; in some cases brick fell inside and either stopped the draft entirely or so impaired it that other arrangements had to be made to take care of the smoke until the débris could be removed. Finally the conditions reached that point where it was deemed advisable to build a new stack. This work was started and completed under the direction of S. S. Sorensen, the chief engineer, and under the direct supervision of Alma Ek as engineer in charge. On the completion of the new stack it was decided to destroy the old one, and this work was given to J. D. Watson, civil engineer for the company, under whose supervision the plans were laid and successfully carried out as herein described. The stack was originally 250 ft. in height

COLLAPSE AND REMAINS OF STACK AFTER DYNAMITING.

erably worse condition than any of the other three. On this side small cracks, such as were on the other sides, started at the base and extended upward to within 50 ft. of the top where the largest crack in the stack began. This crack gradually widened until at the top there was an opening from 3 to 3½ ft. wide. Due mainly to this crack on the west side there was a very pronounced swelling in the last 40 or 50 ft. when viewed from the north to south, but not so noticeable from the east and west.

The stack at the time of its destruction was estimated to weigh approximately 2,016,000 lb., and from this weight the following method of dynamiting was decided on by Mr. Watson as that best suited to the conditions. Eleven holes were drilled 7½ ft. above the concrete foundation, as is shown in the sketch, and of the sizes shown in Table II.

TABLE II

| Hole No. | Width, in. | Height, in. | Length, in. |
|----------|------------|-------------|-------------|
| 1 | 11 | 9 | 23½ |
| 2 | 13 | 9 | 24 |
| 3 | 12 | 8½ | 24 |
| 4 | 12 | 8½ | 24 |
| 5 | 24 | 6½ | 24 |
| 6 | 14 | 9½ | 25 |
| 7 | 9½ | 9½ | 22½ |
| 8 | 9½ | 9½ | 23 |
| 9 | 12 | 9½ | 23 |
| 10 | 12 | 7 | 22 |
| 11 | 12 | 6¾ | 23½ |

It was decided that approximately 200 lb. of Hercules E.L.F. 40% would be sufficient to do the work, and how well calculated the amount was is graphically shown by the photographs. The holes were loaded in the following manner. Each hole was first loaded with its apportioned share of powder, in the middle of which was a stick containing an electric detonator with a 35-ft. lead. The detonator was inserted about 3 in. into its stick of powder. After each hole had been loaded in the manner above stated, great care being taken to see that the powder was in

a most compact mass, a black plastic converter mud was used to wad the holes. This was tamped thoroughly around the powder and out to the surface of the stack, making a very solid charge. The amounts of powder placed in each hole, together with the total, are shown in Table III.

TABLE III

| Hole No. | Powder, lb. | Hole No. | Powder, lb. |
|----------|-------------|----------|-------------|
| 1 | 14.0 | 7 | 8.5 |
| 2 | 16.3 | 8 | 12.9 |
| 3 | 13.3 | 9 | 23.7 |
| 4 | 13.8 | 10 | 13.8 |
| 5 | 26.2 | 11 | 13.1 |
| 6 | 34.5 | | |
| | | Total | 190.1 |

PLAN OF STACK SHOWING ARRANGEMENT OF HOLES FOR FIRING.

The electrical connections for firing the blast were made by R. E. Middagh, chief electrician for the company, and were as follows: The eleven holes were connected in series and then to a line running approximately 500 ft. to a switch connected to the 110-volt lighting circuit. This switch was equipped with plug

fuses, which were not put in until the last minute in order that under no condition would there be an accident due to premature explosion.

When everything was ready, on March 1, the word was given and the switch was thrown, setting off one of the most successful shots of its kind ever fired.

The way in which the stack fell is well worth mentioning. From pictures taken at the time, some of which accompany this article, it seems that the shot blew out the entire base above the concrete foundation and up about 30 ft. The stack then fell straight down until its lower edge hit the foundation, at which time it seems to have telescoped on itself, making one of the most spectacular and successful falls on record. It is well to record here that in spite of the apparent bad condition of the stack in general, and the top in particular, that practically no cracks appeared until it had started to telescope; neither was much of the top loosened, although some little of the latter did fall. The entire stack fell in a pile about 50 ft. in diameter, with the exception of a few bricks which scattered to a distance of about 80 ft., due chiefly to the force of the explosion.

The new stack situated 145 ft. west by south and the two oil reservoirs situated 100 ft. north by east were not damaged. Two bricks fell through the roof of these reservoirs and constituted the entire damage done by the shot except for the destruction of some light wires which were in the danger zone and were not attempted to be saved.

Mining in the Choco District, Colombia

The gold-mining district extends from the junction of the Negua and Atrato rivers south to the mouth of the San Juan. Almost all the deposits are alluvial. There is only one large company at work in the field, formed with British capital, which is extensively sampling with drills and tunnels on the Condoto river, an affluent of the San Juan.

Most of the gold and platinum exported is obtained by native women, working two or three hours per day. They use the antiquated ground-slucing process as a preliminary to get rid of the coarser gravels and then with their *bateas* separate the metals from the sand and gravel. The *batea* is a wooden pan, shaped like a very shallow inverted cone 18 in. diameter and 3 in. deep at the centre, with two small handles or knobs on the rim. The women handle the *bateas* with great dexterity, throwing off the gravel and sand by a rotary motion and leaving the gold and platinum dust in the common centre. Another method of mining that is extensively employed by these women is diving into 3 or 4 ft. of water for the sand and gravel containing the metals and bringing it up in the *bateas*. This method is usually more remunerative than the sluicing process.

The gold workings have existed for centuries, but little has been done in the development of the district. The river gravels were being washed by the Indians

long before the advent of the Spaniards, and this region furnished much of the gold that was carried back to Spain. In those days the value of platinum was unknown, and when the Indians brought the metal down to the Spanish headquarters in Quibdo the platinum was thrown away. Large finds of this discarded metal have been made recently in Quibdo, and frequently the earth excavated for foundations has yielded sufficient platinum to pay for putting up the building. The natives were beginning to pan even the streets, thus uncovering large amounts of mud, which was injurious to health. A decree was therefore promulgated in 1913 prohibiting any further washing of earth in the streets of Quibdo.

Besides the *batea*, the only tools used are the *almocafre* and the *barra*. The former is a kind of hoe 4 in. wide, tapering in a curve to a sharp point that extends back toward the operator. The handle is approximately 18 in. long and 1½ in. diameter. This tool costs 80c. to \$2, the price depending upon whether it is made of iron or steel. The *barra*, which takes the place of a pick, is a small iron or steel crowbar, 1¼ in. diameter and 32 to 40 in. long. A *barra* of iron with a point of steel costs \$1.20 to \$2, while one entirely of steel costs \$2.80 to \$3. The price of a *batea* varies from \$1 to \$2. All the tools are locally made except a few of the *barras*. Since every woman in the mining district is a miner, it might be advisable for American tool manufacturers to investigate this market. Better quality tools could doubtless be sold in the Choco at lower prices than those quoted, but the styles offered should be identical with the ones now in use.

By a law that went into effect in 1910, foreigners are not allowed to denounce or purchase mines in the Choco, but mining property can be leased for a long period or obtained on other advantageous terms. It is expected that within a few years mining on a large scale will be begun in this district. Even under the primitive mining conditions of today the Choco stands second only to Russia as a producer of platinum and the prospects under improved methods are considered favorable.

Mining prospectors should come supplied with shovels, picks, tools, canned goods, guns, and ammunition, as it might be difficult to obtain anything but fresh provisions in Quibdo at reasonable prices. Laborers can be hired for 50 to 70c. and canoes for 20c. per day.—*Daily Consular Report*.

Banking and blowing-out iron blast-furnaces have quite different meanings. The former refers to an interruption in the making of pig iron, for a day or a week or two, when the furnace is filled with coke and kept at a red heat by a light blast. This costs only a few hundred dollars. When a furnace is to be idle for a month or more, it is emptied and allowed to get cold. Blowing-out costs several thousand dollars, and every furnace must be blown-out once in three years or so for relining.

Filter-Press Operation

By A. W. ALLEN

The displacement of valuable solution from residue in the operation of a chamber filter-press is generally effected by one of two means. Where all solid plates are low pressure, the outlets are always open to discharge and no drain cocks are necessary. The pulp is forced under pressure into the press and the solution filters through the cloths which hang between the solid plates and the hollow frames. The former have a channeled surface to facilitate the even flow of solution from the filtering area. Cake formation starts over the whole surface of the cloth and continues until the frame is completely filled with caked slime. A distinct line is traceable vertically through the centre of each cake. This line constitutes a zone of division which is noticeable when the presses are being discharged 'dry' by hand. The displacement of residual solution carrying metal is effected by a wash operating through the same channels as those traversed by the pulp and charge solution. The wash solution or water enters the filling port in each frame, traverses the zone of division in each cake, and passes through the cake on either side of the centre line, through the filter-cloth, and thence to the discharge launder. The same system of washing may follow the part filling of the frame so that a clear space is left between the separate cakes formed on each cloth. In this instance, however, the advantages of a slightly higher washing efficiency are more than counter-balanced by the fact that satisfactory removal of the excess wash left in the hollow space is a difficult matter. Compressed air is only partly effective in reducing such moisture content because, however applied, it will find its way through the top of the cake where there is a minimum moisture content to the avoidance of the lower portion where there is an excess. In a dry discharging press this method results in a sloppy residue, and, under any circumstances, an unnecessary loss of wash. In the second method of operation the low-pressure plates alternate with high-pressure plates and the outlets from the latter are controlled by suitable valves. The low-pressure plates, as in the other system, are open to discharge at all times. During filling all discharge valves are open but as soon as the cake is formed the high-pressure plate discharge valves are closed and wash is forced in, through a separate channel, to the high-pressure plates. This solution finds its way through the cloths over the high-pressure plates and diagonally across the cake of slime, through the cloths covering the low-pressure plates, and thence to the discharge launders. Given similar conditions of operation it has been found that the efficiency of operation by either method is dependent on the thickness of the frames into which the cakes are formed, that is, the thickness of the cakes themselves. The cross-washing system, with high-pressure plates, gives excellent results where the thickness of the cake is not too great. On the other

hand, the median washing system is preferable where it is more economical or necessary to form thick cakes. As in all other classes of filters and filter-presses, the efficiency of displacement is largely affected by the thickness of pulp being handled, rapid cake formation being the surest preventative of a segregation of coarser material in the lower portion of the frames.

Hoisting at the Argonaut Mine

By M. W. VON BERNEWITZ

Both steam and electric hoists are operated at the mines along the Mother Lode of Amador county, California, but that at the above property, at Jackson, is of more than passing interest. The main shaft is down 4100 ft. on the incline, from the surface to 1600 ft. being at an angle of 63°, and from 1600 to 3900 ft. it is 58°. The hoist is on the hanging-wall side, and from centres of the drums to the head-frame sheaves is 300 ft., slack in the ropes being taken care of by three sets of grooved idlers. The machine was built by Knight & Co. of Sutter Creek, whose works are about three miles from the mine. It is a geared hoist, the pinions having 22 and the spur wheels 108 teeth, both with 3-in. pitch, with diameters of 21 and 108 in. respectively. The two drums are 6 ft. diameter

SURFACE VIEW OF ARGONAUT MINE.

with a 35-in. face each, and carry 7 layers of 1 1/8-in. diameter crucible-steel rope. There is a post brake on each drum flange, and also brakes on two flywheels on the pinion shaft. Clutches are operated by hand levers.

To drive the hoist, there is in front, to one side, a Westinghouse induction motor, type H.F., of 500 hp., 440 volts, 60 cycle and 3 phase, running at 440 r.p.m. at full load. On its shaft is a 42-in. diameter grooved pulley for twenty 1 1/4-in. hemp ropes, driving a 96-in. diameter wheel on the hoist pinion shaft. These ropes are in reality endless in two sections running over ten grooves each, having the usual tension pulleys on a frame above. They have been in use so far for 2 1/2 to 3 years. The motor is controlled by a master switch and a Westinghouse liquid (2% soda solution) rheostat, and has the usual safety and

recording devices. The ore-skips will hold four tons. The mine is equipped with electric signals and telephones.

In case of mishap to the electric motor, the hoist may be driven by water power, there being a 6-ft. Pelton wheel, operated under a 240-ft. head, from two lines of 18-in. pipe, 1900 ft. in length. A pulley on the Pelton shaft drives another on the hoist pinion shaft by five 2-in. ropes. A chart showing the power absorbed in hauling from various levels was to have accompanied these notes, but on account of changes in the shaft of late, this cannot be procured at present.

A similar although a little more elaborate hoist is used at the South Eureka mine, only instead of there being one motor there are two 400-hp. General Electric motors coupled to the small rope pulley which in turn drives the pinion shaft. Results from this style of power transmission are entirely satisfactory.

Ore and Dump Train Service*

1. All enginemen, firemen, brakemen, switchmen, and others in train service must be familiar with the rules and regulations and the signal rules, color signals, hand, flag, and lamp signals, and engine whistle signals common to general railroad practice, and particularly as prescribed by the Nevada Northern Railway Co., with whose main line the Company's pit, yard, and dump tracks make connection.

2. Enginemen must signal by whistle when approaching track connections, road crossings, and curves where view is obstructed, and also when nearing steam-shovels in pit, and any and all places in and around the workings where men are at work on or near tracks.

3. Never start engine without first ringing bell.

4. Headlight to the front and rear of all engines must be displayed at night.

5. Under no circumstance must headlight be concealed while engine is moving.

6. Any defect or improper condition of the engine must be reported by engineman to the master mechanic, and at end of each shift such repairs as are required must be entered on the work book.

7. Any defect, bad order, or impaired condition of hand-holds, grab-irons, footboards, brakes, or other equipment of cars or engines found or noted by an employee must be reported promptly to his foreman or to master mechanic.

8. Employees must not remove any of the appliances from an engine or car for convenience in switching, or for any other purpose, thereby endangering the safety of themselves and others.

9. Employees must not attempt to make couplings of cars, or engine and car, if coupling apparatus is found out of order. If examined and found in bad order, report same at once to master mechanic.

10. The dangerous and unnecessary practice of trying to make a coupling with the foot, by kicking the drawbar as cars approach, is positively forbidden.

11. Employees are prohibited from going between moving cars to uncouple, open, close, or arrange knuckles or couplers, or for any purpose whatever.

12. In all service stops of car or cars in train on main tracks, sidings, or service tracks, when engine is cut off, all brakes must be set and cars blocked to hold the train.

13. Employees must not stand between the rails and attempt to get on the front or rear end of an engine or the end of a car as it approaches them. All engines and cars are equipped with grab-irons and when necessary for employees to board moving trains they must stand outside of rails and get upon side of car or end of footboard of engine.

14. Employees must avoid walking on tracks, and are hereby warned that they must not rely upon others to notify them of approach of train.

15. To avoid the danger of being struck by rocks, coal, or other article falling from moving cars, employees must not remain near the track when trains are passing.

16. Employees, other than the regular train crews, are prohibited from riding upon ore or dump trains without special permit from the superintendent. And employees so riding on permit are strictly prohibited from jumping on or off trains or engine while train is in motion.

17. Car repairers, trainmen, or other employees, while working under cars, must make it an absolute rule to protect themselves by flag or light.

18. Track foremen are instructed to keep all frogs, switches, and guard-rails properly blocked. It is the duty of all employees, for their own protection, to report promptly the absence of necessary blocking.

Danger From Falls of Rock

By far the greatest source of danger in tunnel work is from falls of rock. These can be prevented in a large measure by promptly and adequately supporting the roof. Insist that necessary timbering be done, and always keep a supply of lumber for this purpose. Timbering is laborious, and it either takes the men of the tunnel crew from their regular work or requires extra men. If extra men are used, they add to the confusion in the heading, and as their work is done at the same time as the other work of the tunnel, it seriously hinders either the drillers or the shovelers, or both. So, although you may suspect that the roof is dangerous, you may be tempted to delay timbering—possibly until an accident brings the necessity forcibly and unavoidably to the front. Remember that all necessary timbering cannot be done too soon, and that any delay seriously jeopardizes the lives and limbs of the men who have to work under a roof improperly supported.—Miners' Circular 13, Bureau of Mines.

*From the book of 'Rules and Regulations' of the Nevada Consolidated Copper Company.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Geology of the Kalgoorlie Goldfield

The Editor:

Sir—In reply to the leading article in the *Mining and Scientific Press* of July 12, 1913, and your request that I should add some remarks to the articles on the 'Geology of Kalgoorlie' by Mr. Maclaren, it is needless to say I have much pleasure in discussing that gentleman's work. But I do so with much diffidence, for I highly appreciate the excellent work carried out by Mr. Maclaren on this field, with which there is nothing to compare. Moreover, I owe much to his courtesy and generosity. As a matter of fact our views coincide very closely. But the work carried out since the publication of my book on the 'Geology of Kalgoorlie' in 1912 has brought to light certain points which do not entirely agree with the views of Mr. Maclaren, if I have read this article and reports correctly, and which I venture to think may be of some importance to the future of this field.

Furthermore, as pointed out in your editorial of July 12, the question of nomenclature is one that requires settling, in the interests of managers, in order that the maps may all have the same set of names for the rock formations in each mine, a factor to my mind of prime importance.

NOMENCLATURE

The importance of this subject has just been referred to, and I think the time is now ripe for a settlement of the question. But unless two authorities agree, or one is entirely accepted, there is no hope of finality being reached. Detailed arguments will be used when discussing each rock, but it is clear that Mr. Maclaren admits the chaotic condition of rock nomenclature, for in speaking of quartz-dolerite (quartz-diabase) he says: "Many pairs of names are now engaged in a battle for existence, and it will be a generation before these struggles are ended." I think this remark could well have been extended, for, apart from pairs of names, the nomenclature of the older greenstones and other rocks will perhaps be several generations before finality is reached. Take for instance the calc-schist. Mr. Maclaren admits, "The name calc-schist has a very general significance and gives no clue to the original character of the rock, which may have been tuffs or ashes or lava flows." (I called the same rock metamorphic tuff). These remarks clearly show the difficulty surrounding the subject. Furthermore, I think all geologists are agreed upon the impossibility of different authorities

giving the same name, though they may agree in every other respect, to highly altered rocks in the Archean Complex.

Quartz-Dolerite.—(My 'quartz-andesite'; Maclaren's 'quartz-dolerite greenstone or chloritic rock with micropegmatite'.) This is Mr. Maclaren's quartz-dolerite greenstone. It forms the country rock of the chief mines on the field, and is in consequence perhaps the most important.

In order to show the diversity of opinion with regard to the name of this rock, apart from the fact that we all agree as to its constituents, I give the following names applied by different authors:

| | |
|-------------------------|----------------------------|
| Maclaren | Quartz-dolerite greenstone |
| Larcombe and Judd | Quartz-andesite |
| Simpson | Prophyllite |
| Gibson | Quartz diabase |
| Card | Acid eruptive |

Mr. Maclaren says: "It has not been found possible finally to determine the original character of the rock from a single specimen, and it is only after the consideration of several hundreds of rock slides that the character of the original rock has been reconstructed. It has, therefore, been necessary to indicate that the freshest rock now to be found is yet a much altered one; and this has been fulfilled by the selection of the term 'quartz-dolerite greenstone'; that is, a somewhat indefinite rock derived from quartz-dolerite and one that would fall into the old, useful, field group of greenstones."

These remarks clearly indicate the difficulty in finding a name. I called the same rock quartz-andesite, and my reasons for doing so are well summed up in the following remarks on page 306 of my book, as follows: "The most important result of the examination of these deep-seated rocks is to show that they are undoubtedly holocrystalline, and contain a very large amount of felspar. It consequently follows that the practically irresolvable base in the specimens from the higher levels is produced by the decomposition of the minerals in the parent rock to carbonates, chlorite, sericite, etc., certain crystals remaining as apparent phenocrysts."

Maclaren says: "It is this porphyritic appearance, together with the destruction of the other original minerals, that has led Judd and others to describe the rock as a quartz-andesite." It therefore appears that I followed the same course as Judd, and being practically the first extensive writer on this field I was at a loss what to call this rock, which I realized was an intermediate stage between quartz-gabbro, quartz-dolerite, amphibolite, and such highly changed rocks as the graphitic slates and quartz-sericite carbonate rocks. Moreover G. W. Card, government mineralogist in New South Wales, repeatedly made use of the terms 'matrix', 'base', 'groundmass', and 'interstitial matter', when describing this rock after a thorough microscopic investigation.

As regard 'quartz-diabase', there is no doubt this name might well be used by the older school. But Harker is now doing away with this name, which I think is a good scheme. He would now say altered-dolerite instead of quartz-diabase. I therefore think if we refer the country rock of the Golden Mile to its original, then the name quartz-dolerite used by Mr. Maclaren is the best, and should be generally adopted.

Bleached Dolerite.—(My 'granophyric-dacite', Maclaren's 'bleached and carbonated rock with micropegmatite.') This is a characteristic pinkish rock, varying in texture from coarse to fine grain. It has practically the same constituents as the quartz-dolerite, but contains less chlorite, often none, and more carbonates and sometimes sericite. I called it granophyric-dacite because the leaching of the chlorite from the quartz-andesite (quartz-dolerite) seemed to show up the granophyric texture. I have regarded this rock as being in part due to a slight differentiation in the original magma, and in part to a process of leaching. Having adopted the name quartz-dolerite I suggest that this particular pink and grey variety might for shortness and convenience be regarded as 'bleached dolerite'. These bleached forms of the quartz-dolerite are very characteristic, and at the same time they have certain economic significance, so that I venture to think this name will be very useful.

Aphanite—(My 'aphanite', Maclaren's 'non-chloritic carbonated and sericitic rocks, with micropegmatite and schistose varieties'). The use of this term has led to a considerable amount of controversy, but continued experience has caused me to adhere to it. When I speak of aphanite I mean the dense, compact greenish rock, which is only an altered form of the quartz-dolerite surrounding the lodes. In boring on the western side of the field it has served as an invaluable indicator of the presence of lodes, particularly in the Great Boulder and Horse-Shoe mines. Of course, all lodes do not have this aphanitic product along their walls especially on the eastern side of the field, but on the western side it may be over 100 ft. thick and is exceedingly characteristic and important.

This rock at deeper levels is indistinguishable from the felsite (albite-porphyry), and its recognition has, I hope, proved of considerable economic importance to the Horse-Shoe mine. For what was apparently taken for felsite, an unfavorable rock as regards lode formations, has proved to be aphanite. As an illustration, the 1900-ft. level of the Great Boulder mine at the main shaft appears to be surely in felsite, but microscopically the evidence is strongly in favor of aphanite or altered quartz-dolerite, probably close to the western or hanging wall of the felsite. For at deep levels the edges of the felsite are often aphanite. The recognition of this fact has considerably reduced the thickness of the felsite.

The word 'aphanite' is often used in an adjectival sense (aphanitic), meaning not apparent to the unaided eye whether crystalline or not. But I see no reason why

the term 'aphanite' should not be applied to a rock wholly aphanitic, for James Geikie uses the term aphanite for a compact diorite and modern text books, such as Iddings, include for field purposes all aphanitic rocks, whose component crystals are so small that they cannot be seen and recognized by the unaided eye, under the general heading of 'Aphanites'.

A study of the Horse-Shoe plans shows the importance of this rock as an indicator in boring, and as it is easily separated from the quartz-dolerite in cores, and as it is the most favorable lode carrier on the field, I respectfully ask for the acceptance of the term aphanite, or a single term that every one will use, for this quartz-sericite-carbonate rock is one of those that may perhaps never receive a place in rock nomenclature.

Slates.—(My 'carbonaceous slates'; Maclaren's 'graphitic slates') There is no difference between Maclaren and myself as far as the name applied to the black bands in the altered quartz-dolerite is concerned, so at this point there is nothing further to be said. But later I shall discuss the different classes of 'slate', their influence on lode formations and the possible origin of the carbon.

Felsite.—(My 'felsite-porphyry', Maclaren's 'albite-porphyry'). This is Maclaren's albite-porphyry and I called it felsite-porphyry because it is essentially a felsite, though at times small crystals of felspar are observable. Continued examination at deep levels convinces me that felsite is the best name, for it is rarely that phenocrysts are observed even with the microscope. I therefore trust that the term felsite will be adopted. On account of the importance of this rock a somewhat detailed account of its occurrence and relation to lode-formations will be given later.

Calc-Schist.—(My 'metamorphic tuff'; Maclaren's 'calc-schist'). As far as the actual nature of this rock is concerned Mr. Maclaren and myself are in accordance, for although he calls it calc-schist he believes it to be metamorphic tuff. The indefiniteness of the name has already been referred to, for Maclaren says: "Calc-schist is an indefinite rock characterized by abundance of secondary carbonates . . . and gives no clue to the original nature of the rock." Furthermore my experience has been that the rock is for the most part massive, and not a schist at all except in local areas. Mr. Maclaren evidently recognized this fact, for he says: "This dike (rock) has been provisionally termed calc-schist though the schistosity is not strongly marked."

I am more than ever convinced that the calc-schist is a phase of the older greenstones, and as first suggested to me by my student, F. W. Rowe, probably represents the altered edge of the fine grained amphibolites along their contact with the quartz-dolerite. Consequently, whatever origin is finally attributed to the fine grained amphibolites must be the same for the calc-schist. Perhaps the original was a tuff though it may yet prove to be a lava flow. However, as the term calc-schist has got such a hold on the mining public of Kalgoorlie,

and it is shorter than metamorphic tuff, I trust the term will be allowed to remain. Its economic significance and position on the field will be again referred to.

PROPOSED CLASSIFICATION

Having regard to the foregoing arguments, I respectfully suggest that mine managers will see their way clear to finally adopt the following amended rock classification, with which it is my earnest hope Mr. Maclaren will agree, as I feel sure he will in the interests of all concerned. I can only once more repeat the concluding paragraph in my book, published in 1912: "It is to be hoped, in the interests of all concerned, that in writing of the Golden Mile, geologists will come to a compromise and agree on a definite name, not only for this rock, but also for each of the other five characteristic rocks on the Kalgoorlie field, and thus prevent the confusion that must otherwise inevitably arise, especially among those who are not familiar with geological nomenclature." If this were done we would be doing much in the interests of all who by their loyalty, energy and enthusiasm are endeavoring to uphold the great mining industry."

AMENDED CLASSIFICATION OF KALGOORLIE ROCKS

| Maclaren. | Larcombe. | Geological Survey. | Amended classification. |
|---|-----------------------|-----------------------------|-------------------------|
| OLDER GREENSTONES | | | |
| Calc-schist | Metamorphic tuff... | Calc-schist | Calc-schist |
| NEWER GREENSTONES | | | |
| Peridotite | Peridotite | Peridotite | Peridotite |
| Pyroxenite | Pyroxenite | Basic amphibolite | Pyroxenite |
| Quartz dolerite greenstone (chloritic rock with micropegmatite) | Quartz-andesite | Quartz-diorite | Quartz-dolerite |
| Bleached and carbonated rock with micropegmatite (granite of the miners at Kalgoorlie).... | Granophyric diorite. | Carbonated-diorite | Bleached dolerite |

Since writing the above it is my pleasing duty to say that Mr. Maclaren has read my statements, and, after conferring on the subject he has asked me to say that he entirely agrees with my amended classification. I think we owe a great debt of gratitude to him for compromising in this way, and I sincerely trust managers and all concerned will adopt the new rock classification. For in years to come, when perhaps trouble may arise, and all maps are colored or marked according to this scheme, geologists will probably be able to give valuable advice.

For many years it has been my ambition to have this matter settled, and personally I cannot thank Mr. Maclaren sufficiently for coöperating with me and thus bringing order out of chaos as far as the Kalgoorlie rocks are concerned, for I feel sure he has thereby materially helped the furtherance of our great mining industry.

C. O. G. LARCOMBE.

Kalgoorlie, January 12.

What Is the Matter With Prospecting?

The Editor:

Sir—In some of the replies to your question, 'What is the matter with prospecting?' there is much food for thought. The subject is one of moment and should be thoroughly gone over and a remedy found. That there are new fields still unexploited, ample proof exists. That the prospector finds it hard to interest anyone, is clear, and just why is the question. Some of the answers seemingly touched lightly upon the most vital point—money for prospects—dismissing the subject by saying there seemed to be plenty for that purpose. Where is it? Just what are the proper methods to apply for it? Where may the prospector apply for it? Since the boom days, prior to 1907, I have found money for opening up a prospect getting scarcer all the time, until at present there seems to be none. Why is this?

I ascribe it to the advent of the automobile as the main reason. The many millions now sunk in the 'auto' once was available for opening a prospect. Prior to the advent of the 'auto' it was no difficult matter to find a man who would 'take a chance with the prospector to open up a property. Surface showings

would induce him to rely upon his own judgment and take a chance. Veins must be exposed, the ground surveyed, tests made, etc., all of which costs money and time, before the big capitalist will listen to the prospector. Then the matter is referred to the engineer who must be able to see and measure, and test. He does not permit romance, adventure, prospector's visions, borne of hope, to enter into his report. Facts, figures, and measurements, make entirely different reading as compared with the prospector's description. The result is that many a prospect is lying idle or going begging. The engineer stands between the prospector and big capital. The automobile has taken the little capital. The old style prospector was useful in his way. True, he had failings, was full of visions, indulged in dreams, but nevertheless furnished a means for capital to work on. In discarding him for the engineer and the geologist there seems to have been a great decline in new discoveries and new fields. Some

of the gentlemen ascribe this dearth to no new fields, territory exhausted, etc. There is ample proof to the contrary. If the prospector could but connect with this 'plenty of money for prospects.' There are many finds laying dormant, for want of capital necessary for first work and clearings, that they may be 'shown' and referred to the engineer for report. The average prospector has no money; he has plenty of time and energy, but it takes tools, powder, and grub to show up a prospect. The man of small capital who would take a chance is no more. Ready market or assistance has been curtailed by legislation, and the automobile. The former has handicapped his flights of imagination, the latter his source of revenue. Big capital must be 'shown,' where it is not controlled by the old spirit of romance and adventure, hopes, and visions. These led the prospector into all sorts of places, and induced the man of small means to 'take a chance.' It depends upon the geologist and the engineer, with their useful scientific knowledge. But I never heard of either class finding anything; it is always the prospector who shows the way. How, then, help the prospector by government aid? This is impractical, and he doesn't need it. Just show him the 'proper channels' mentioned; just let this 'plenty of money for prospects' come out into view; just deal generously with his hopes, make allowances for his visions and dreams. He is useful, in a way; he cracks many a rock, digs many a hole, penetrates into many places that would be considered foolish, and a waste of time and energy, by the capitalist and capital. Led on by these same hopes, visions, and dreams, that have shown where capital might profit, and the world be benefited. Scientific exactitude and efficiency, conservation of time and energy, is no part of his makeup. These can be brought to bear after he has blazed the way to a 'find' which would lay hidden if left to the geologist or engineer. Not that they couldn't find, but they don't. S. A. Knapp covered the subject well as far as he enumerated. He should have added another statement, thus: "It takes money to open a prospect." This is where the big capitalist 'balks.' The prospector would dig to see. The capitalist wants to 'see' first. The prospector does not count time and money wasted if he gets no immediate returns. He is led by hope and faith to repeated effort, undaunted by failure.

A capitalist wants returns, expects and demands them, and cannot tolerate failures very long. I know of one man who had ten outfits out for him, covering a period of 18 months. Eight returned nothing on his investment. One made enough to cover all his expenditures for the entire number. One found, for him, that which yielded a million and a half in money, and still yields rich returns. He had the nerve to stand up under many disappointments. He 'took a chance' and told me he did not consider the eight that yielded nothing as money wasted; on the contrary, it was well spent, and he would do it again, or would have

continued, but felt that he had found plenty for his needs. He did not consider prospectors an unreliable lot, as was stated by one of your correspondents. It is this latter spirit that is killing off the new finds and fields. Another factor which enters largely between the prospector and large capital is the field representative. Some large mining companies have men out looking for properties. They are capable men, but they cannot see any farther into the ground than the engineer or prospector. They are under salary and it does not behoove them to make very many mistakes. If they cannot see, measure, and test, there is little chance to do business. Even then it is sale only—no partnership with the prospector and letting him share with the developments, but outright control, based on developed showing, if any. The prospector's capabilities are limited; were it otherwise he would not need a financier. I have often heard the term 'crazy prospector' applied to them, and it may seem so to the comfortably housed, scientifically regulated person. But he has been a benefit to the world, and is still useful.

There is a wide, deep chasm between the prospector and capital, which is difficult to bridge. The material once used for that purpose is gone; that is, the promoter and the man of small capital and ambitions. The former is active in real estate, where there seems to be no restrictions upon imagination. The latter is with his automobile.

I am a prospector and speak of conditions as I have found them. Immediately following 1907, the prospector fell into disfavor. But mining is coming into its own again. Let us hope the prospector will also—such at least is the hope I cherish.

C. P. GREENE.

Descanso, California, April 3.

The gold production of Nova Scotia from 1862 to 1910 has lately been published by the Canadian Geological Survey. In 1863 the total gold extracted amounted to 14,001 oz. while in 1867, it amounted to 27,314 oz., when the output began to decrease until 1881 it was but 10,756 oz. It again began to increase and high-water mark was reached in 1898 with 31,104 oz. For several years longer, until 1904, the gold output kept up well, but in that year, 1904, it began to drop and in 1910 the output was but 10,325 oz., or one-third its maximum. For the past year or two the gold output has been on the increase, last year, 1913, to a marked degree.

A windmill, with steel sails and mounted on a steel tower, and having a diameter of 50 ft. has started work in Holland on a drainage scheme. It has a capacity of 64,000 to 70,000 cu. ft. (40,000,000 to 43,750,000 gal.) per hour, and is said to be the largest in the world. Gasoline motors took the place of wooden windmills in 1908, but steel windmills have displaced the motors.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Coal production of Ombilien, Sumatra, Dutch East Indies, was 411,083 tons in 1913, against 408,204 tons in 1912.

Permanganate solutions used in the analysis of iron ores is approximately 22.5 gm. of $K_2Mn_2O_8$ to 8000 c.c. of distilled water.

The weight of a cubic foot of air at an altitude of $31\frac{1}{2}$ miles is approximately half of what it is at sea-level. At an altitude of 7 miles it is less than one-quarter.

Small leaks in newly erected steel tanks may be stopped by filling the tank with water and stirring into this a small amount of cement. Leaks in wood tanks may be stopped with sawdust in the same way.

Dredging costs of the Renong Dredging Co., in Siam, are 5.4c. per cubic yard. Other eastern expenses increase this to 8.2c., while taxes, royalty, agents' commission, selling charges, make it 11.2c., and depreciation and London expenses bring the total to 12.8c. per yard.

Uranium ores of Colorado and Utah do not contain pitchblende as a rule, but the brilliant yellow uranium mineral carnotite, according to E. S. Bastin of the U. S. Geological Survey. The only pitchblende production of the United States is from one locality in Gilpin county, Colorado. The only other places in the world yielding this mineral are the Erzgebirge in Austria and Germany, and Cornwall in England.

Box gives the following formula to calculate loss of head in a pipe-line as a result of friction:

$$h = \frac{q^2 \times l}{(3.14)^5}$$

where d = diameter of pipe in inches,

l = length in yards,

h = head of water in feet,

q = gallons per minute.

Paper must be fitted to the purpose for which it is to be used, and this is by no means a simple matter. Recently Arthur D. Little pointed out some of the complexities involved, saying: "A paper for wrapping hardware or a card for mounting silver jewelry may seem to possess every desirable property, and yet be worse than useless because of a trace of sulphur. A printing paper may develop 'whiskers' or clog the type by mineral fillers; a coated paper may pick or develop

odor, a cigarette paper may burn badly, a writing paper may allow the ink to spread because the size has been converted into peptones by overheating, a filter paper may fail to hold a fine precipitate or unduly retard the passage of liquid, and so on."

Taking water from a 'dinkey's' tender for a 70-C Bucyrus shovel, when the supply pump was not working and without delay in digging, has been done as follows, according to the *Excavating Engineer*: Ordinarily the water-supply was pumped through a $1\frac{1}{4}$ -in. pipe-line. Occasionally the supply pump for one reason or another could not be used. A shovel foreman kept his shovel supplied with water without any delay in digging, by taking it from the locomotive's tender. This was done only when loading the car next to the locomotive, the amount in this manner sufficing until the next train of empties arrived. The injector which came on the shovel was found to be big enough for this duty.

It is important that the zinc in precipitation boxes should be evenly deposited in the compartments. To this end the shavings should be spread out into as large and loose a bulk as possible before being packed into the box. If this is not done there is a liability to channeling, especially at the corners. Any short-circuiting will diminish the capacity of the box and will allow the distribution of the deposited metal over a number of compartments rather than the concentration of nearly all the gold and silver in the first compartments. A simple way of finding out as to whether or not any particular compartment has been efficiently packed is to add a few drops of phenolphthalein in alcohol to the solution entering it. Any channeling, as a result of bad packing, will be immediately noticeable by the rapid appearance of a red coloration at the corners of the compartment.

Centrifugal pumps, elevating ore pulp, unless in perfect adjustment and regulated to exactly lift the required amount of pulp, will give an intermittent delivery. This can be remedied in some instances by an alteration in the speed, or by throttling the discharge. The former method is inconvenient, and the adoption of the latter practice results in severe wear at the throttling point. Frenier pumps give a constant and steady discharge if due regard is paid to the principles governing their operation. They are, however, incapable of any adjustment, and to insure satisfactory working the exact amount of pulp required must be provided. Three-throw plunger pumps will give a steady discharge provided that all the plungers are working properly. As soon as one valve works indifferently, the discharge becomes intermittent. The air-lift can be made to give a steady discharge even with a wide variation of feed, provided that there exists ample capacity in the rising main and that the air-supply, both as regards pressure and volume, is not in excess of the required amount.

Special Correspondence

TORONTO, CANADA

CHANGES IN IRON AND STEEL TARIFF.—BENEFITS TO COKE MANUFACTURERS.—FUTURE DUTY ON STEEL SHAPES AND OTHER MILLED PRODUCTS.

On April 6, the Hon. W. T. White, Canadian Minister of Finance, announced a number of minor changes in the tariff, principally affecting the iron and steel industries. The application of the iron and steel manufacturers for a renewal of the bounties on pig iron and steel billets, or a compensating increase in the present duties, was not granted, and the matter of a bounty or other encouragement, for the production of Canadian iron ore, was postponed until next session, the Minister of Finance intimating that in the meantime an inquiry into the iron resources of the country would be made by the Department of Mines. The two most important changes were the reduction of the duty on agricultural implements from 17½ to 12½%, a concession to the demands of the western farmers for free agricultural implements, and the imposition of a duty of \$2.25 per ton under British preferential tariff, and \$3.50 per ton under the general tariff on wire rods formerly free. This is coupled with a drawback provision, under which the manufacturers of the staple gauges of wire fencing receive back 99% of the duty paid on the rods. The wire-rod duty meets the approval of the large manufacturing companies, such as the Dominion Steel Corporation and the Steel Company of Canada, whose rod mills have lately been doing poorly on account of the keenness of American competition, but the smaller plants engaged in rail manufacturing will be injured by an increase in the price of their raw material. Instead of being able to import their rods, they will have to buy from the large manufacturers, against whom they will have to compete in the sale of the finished product. It is predicted that some of the smaller firms engaged in rail manufacturing will be forced out of business. It is not anticipated that the cut of 5% in the duty on agricultural implements will have any serious effect on that industry, which is so firmly established as to be able to export largely, though it will intensify competition in Western Canada with their American rivals, who already supply a large portion of the demand.

The coke manufacturing industry will receive a stimulus from a change in the tariff affecting bituminous coal, which is subject to a duty of 53c. per ton. Proprietors of smelters making their own coke for the smelting of ores previously had a drawback of 99% on the coal duty. This drawback has now been extended to proprietors of coke ovens other than those owned by smelting works when the coke is used for smelting purposes. The Hamilton By-Product & Coke Ovens, Ltd., has for some time had in contemplation the establishment of a large coke-manufacturing plant in Hamilton; but its plans have been in abeyance pending the settlement of the tariff question. Now that they are assured of free coal the erection of a \$2,000,000 plant will be proceeded with at once.

In addition to the changes which go into force at once, the Government is asking for authority to impose at any time, when it considers Canadian manufacturers capable of supplying the market, largely increased duties on the heavier grades of rolled iron or steel angles, beams, channels, and other articles known as merchantable milled products. The lighter products of this sort are well protected; but the tariff on the heavier goods is considerably less because they are not made in Canada to any extent. It is understood that the promised increase of the duty will encourage the Algoma Steel Works and perhaps others to encourage this branch of manufacture.

MELBOURNE, AUSTRALIA

AN OLD VICTORIAN FIELD.—THREE IMPORTANT MINES TO CLOSE.
—MINERAL OUTPUT OF NEW SOUTH WALES AND TASMANIA.
—PAPUA AND THE NORTHERN TERRITORY.

Victoria is promised a great accession of strength by reason of the option that has been taken by the Great Boulder Proprietary company of Western Australia over a number of gold-mining areas in the Stawell district. This is an area where a great deal of remunerative quartz-mining has been done in past years. Perhaps its most famous property was the Magdalacum-Moonlight. The field is traversed by a large dike and it is on the western side of this that the bulk of the work has been done. It is probable that the option-holders will prospect the ground on the eastern side, on

the assumption that there is likely to be an extension of auriferous veins on that side. But presumably the chief attention will be paid to the western ground where the lode channel is about 200 ft. wide and consists of large lenticular masses of quartz. If systematically worked, the large low-grade bodies contained in this channel should be profitable.

The approaching closing down of the Tasmania gold mine at Beaconsfield, Tasmania, will throw 400 men out of employment. The water difficulties, from which the mine has always suffered, have increased of late years, and have been accompanied by an unfortunate decrease in the value of the ore, while also the cost of mining has naturally increased as greater depth has been attained. Twenty years ago the mine was still yielding steadily at the rate of \$20 per ton; now its yield is only about \$8 dwt., and ore reserves are practically non-existent, so that it is not surprising that the directors have decided to close down so soon as the available ore has been depleted. The loss on working for the year ended Sep-

tember 30 last was \$15,000, and cash assets were only \$65,000, and subsequent loss on working has reduced this balance to about \$55,000. The decision to close down has resulted from the report of an engineer deputed by the London board to visit the property. The treatment of accumulated products at the company's reduction works will, however, occupy a period of three or four years and yield a total profit of from \$175,000 to \$200,000.

It is not only in Tasmania that a misfortune has to be reported. Queensland also has its trouble to contend with—indeed, not merely one. First, the Chillagoe company, which has always been in difficulties ever since it came into existence, is once more to the fore. The directors applied to the Queensland government for a loan, but their request was refused, whereupon instructions were given for the closing of the smelting works as soon as the stock of coke on hand was exhausted, and the curtailment of all other expenditure till a supply of coal should be available from the Mt. Mulligan coalfield, which the company has purchased. The trouble between the company and the government has reference to the slow progress in the construction of the Mt. Mulligan railway, and the failure to come to any definite terms regarding the sale of the Chillagoe railway to the government. The company states that the heavy loss it has sustained from the dilatoriness in the construction of the Mt. Mulligan line is such as to warrant its stopping all work rather than continue to go on at a loss.

The other Queensland disaster is the announcement of the approaching suspension of operations at the Great Fitzroy. The falling in price of copper is set down as the principal reason, and it is said that further capital will be required, and that the difficulty of obtaining this is one of the actuating motives for the closing down. The company recently acquired the Lalokie copper mine in Papua, and it seems to be thought that some advantage will accrue through the shutting-down of the Queensland mine until arrangements have been completed for the drawing of supplies of flux from Lalokie. But this reason does not seem to be altogether comprehensible.

The New South Wales statistics for the past year are exceedingly satisfactory, the total value of the mineral output for the year having been \$58,657,000, or nearly 4% advance upon the figures for 1912 which constituted a record for the state. The value of the silver-lead-zinc output has made just about the average increase, standing at \$27,751,000. The advance in copper has been rather more than 3%, and that in tin has been nearly 25%. The coal output was a record, amounting to 10,414,165 tons, an increase of more than 5% over the previous year's total. Gold, on the other hand, dropped a little more than 3%, in common with the decline of this metal throughout all the eastern states.

Tasmania's figures for the past year are also available, but are not of as satisfactory a nature as are those of the 'parent state' [It may be explained by the term 'parent state' that in the early history of Australia, Tasmania and Victoria were subject to New South Wales.—EDITOR], the value of its total output, \$6,866,000, meaning a decline of more than 5% on the 1912 figures. Gold has dropped nearly 12%, copper close on to 15%, and tin over 2%, while silver-lead has increased its output nearly 4%. These are the only four important contributors to the total.

A report has been made to the Austral Malay Tin, Ltd., by J. Malcolm Newman, on the prospects of gold-dredging in Papua. The report, which is the outcome of five months' inspection and inquiry, is anything but encouraging. He discovered no dredgable area of sufficient size to warrant extensive operations, and declares that the reports as to the value and production of various areas are gross exaggeration. He further says: "From conversations held by me, on the occasions of my previous visits to Papua, with

prospectors, business men, and government officials, I formed the opinion that from various economic causes, notably expensive living and geographical and climatic conditions, resulted in the working of only the very richest ground, and limited operations to small portions only of the auriferous country. My investigations now lead me to the astonishing conclusion that, owing to the efficiency and cheapness of the indentured native labor for such work, combined with the suitable topography and plentiful water supply, alluvial ground can be more cheaply operated in Papua than probably in any country in the world. I am confident that in many places in Papua 'ground sluicing' has been carried on in ground yielding less than 12c. per yard, and 'box sluicing' in ground worth no more than 24c. per yard."

Quite a boom is being made regarding the Pine Creek field in the Northern Territory. A former government geologist of Victoria has pronounced the field to be another Bendigo, so far as formation goes—that is to say, the gold-bearing quartz will be repeated in saddle after saddle as sinking is done. The survey being conducted by the geological branch of the administration of the territory confirms this view, and great hopes seem to be entertained in regard to the future of the field. It has, however, to be borne in mind that Pine Creek suffers from its situation, and though it has proved remunerative in its shallow workings, it has a long way to go before it can be considered another Bendigo. If it had been that up to date, its remoteness would not have prevented it from becoming one of the great goldfields of Australia.

PORCUPINE, ONTARIO

DEVELOPMENTS IN THE NORTH THOMPSON AND OTHER PROPERTIES.—ACTIVITY AT PORCUPINE.

The Associated Gold Mines of West Australia is quite satisfied with the results of the diamond-drilling on the North Thompson gold mine. The vein in the shaft is developing well and assays are satisfactory. The Sally Gold Mines Co. has moved its machinery to a property in Turnbull, and is erecting buildings. Some diamond-drilling will be done on this property as well. A good deal of free gold has been found in a vein on the Bradley Fournier claims in Carleton township, and the Jamieson claims in Robb township have created considerable interest owing to the showing of gold recently found in them. About 20 or 30 claims have been staked around Jamieson's property in the past three weeks. The Wittsky-Chiry syndicate, in Whitesides township, is sinking its shaft to 100 ft., when 200 ft. of cross-cutting and driving will be done.

The Porcupine camp is busier than it has been for the past two years, and all promising prospects are being examined with a view to purchase. The McIntyre, in driving the Pearl Lake cross-cut at the 600-ft. level, has driven 100 ft. through a sericite schist without using a drill or explosive of any kind. The schist is so soft that it can be picked down fast enough to keep the trammers busy. An investigation is being held regarding the lack of water during the worst part of the recent severe fire at Timmins, when the Hollinger bunkhouses and several other buildings were destroyed. The origin of the fire is a mystery, but it is believed to have originated in one of the bedrooms of the western bunkhouse.

Over 900 tons of nickel ore was shipped from the Alexo mine in March. Mining is done by an open-cut and drift down so far. Sixteen mines contributed to the March shipments from Cobalt. Ore reserves in the Tough Oakes mine are estimated by F. C. Loring at 15,000 tons, worth a profit of \$48 per ton. Five important veins have been proved, two of which are high grade. Geological conditions are favorable for their extension. Sixty feet below the Cobalt Lake's 225-ft. level, a winze is opening 3 in. of 2000-oz. silver ore.

NEW YORK

MEETING OF THE AMERICAN ELECTROCHEMICAL SOCIETY.—INSPIRATION ORE RESERVES.—FIFTY YEARS' COPPER PRICES.—TONOPAH BELMONT, CHINO, AND RAY REPORTS.

The feature of last week was the annual meeting of the American Electrochemical Society, which was held on April 16, 17, and 18. The headquarters of the society was at the Chemists Club, 52 East 41st street. The topic for Thursday morning, following the annual business meeting (at which the election of officers was as follows: president, F. Austin Lidbury; vice-presidents, Carl Hering, W. D. Bancroft, and William Brady; managers, H. C. Parmelee, W. R. Whitney, and C. G. Fink; treasurer, P. G. Salom; and secretary, Joseph W. Richards) was a symposium on power problems in electrochemistry. C. P. Steinmetz discussed the characteristics of electrical energy as affecting chemical industries, after which the problem of power transmission *versus* utilization in local electrochemical industries was presented by P. Sothman. F. A. J. Fitzgerald described some economies in the use of electric furnaces, and power for electric-furnace work was discussed by W. S. Horry. The power problem in the deposition of metals was discussed by Lawrence Addicks and H. E. Longwell, after which F. D. Newbury outlined the sources of direct current for electrochemical processes. The afternoon session was opened with an experimental lecture by W. D. Bancroft on electrolytic flames, followed by two papers on the use of the electric furnace in steel metallurgy by C. A. Hausen and E. B. Clarke, and two papers on zinc smelting by George C. Stone and W. R. Ingalls. A paper on the advantages of southeastern Alaska for electrochemical industries, by W. P. Lass, was read by title. The address by the retiring president, E. F. Roeber, preceded the smoker in the evening, and he was later presented with a stoneware loving cup of 1½ gal. capacity, signifying his great thirst for knowledge as well as his great capacity. The most amusing feature of the evening was a series of wireless telegrams from 'Carranza Chemico' Bancroft, 'Francisco Villa' Saunders, and 'Victoriano Huerta' Parsons, in regard to the metallurgical treatment to be adopted by a zinc mine which was supposed to have been bequeathed to the society. All day Friday was devoted to a steamer trip to the plants of the American Smelting & Refining Co., United Lead Co., and W. C. Clark Wire Works. Luncheon was served on the steamer and an excellent opportunity for seeing these important plants was afforded. The session on Saturday was held at Columbia University, and chiefly centred around the leaching of copper ores. The progress in leaching and electrolytic treatment of copper ores in South America was described by E. A. C. Smith. A number of papers were read by title, followed by interesting discussion. The dinner at the Chemists Club in the evening concluded the session.

In the annual report of the Inspiration Copper Co., the general manager, C. E. Mills, states that the 600-ton flotation plant which has been in operation for over three months has yielded a concentrate more free from silica than was expected from the results in the 50-ton plant. No figures as to the percentage of recovery attained are given in the report, but they are known to be high, and that the management is highly gratified by the results. The present design of the mill involves a preliminary concentration on tables. The total development work done so far amounts to 110,609 ft., and the total tonnage of ore developed is as follows: 45,000,000 tons of sulphide ore, averaging 2% copper; 28,322,000 tons of sulphide averaging 1.26% copper; 12,500,000 tons of oxidized material averaging 1.34% copper; and 2,876,000 tons of mixed sulphides and oxides, averaging 1.24% copper. An issue of 5% convertible bonds has been authorized, as already noted, in order to provide the additional funds required for a branch railroad, more land, a

steam power-plant, and various other items not included in the original estimates.

Charles F. Brooker, who has been for 50 years connected with the American Brass Co., was the guest of honor at a dinner given by the Copper Producers at Sherry's on April 14. In his 50 years' association with that Company, Mr. Brooker has bought over 2,500,000,000 lb. of copper, at an average price of 14.95c. per pound. The fact is of interest as indicating that the present price level of copper is not below normal, since the present cost of production is much below the average for the half century.

The Tonopah Belmont Development Co.'s report for the year ended February 28, 1914, shows that reserves amount

BELMONT MILL, TONOPAH, NEVADA.

to 517,117 tons of positive, probable, and possible ore. The mill treated 172,646 tons yielding gold and silver worth \$4,199,133. Net earnings were \$2,015,588, and dividends \$1,650,000.

The Chino Copper Co.'s report for 1913 shows that 50,511,661 lb. of copper was produced from 1,942,700 tons of ore. The revenue was \$7,621,419, net operating profits \$3,190,293, and dividends \$1,919,070. Reserves total 90,000,000 tons of 1.8% copper ore.

In 1913 the Ray Consolidated Copper Co. milled 2,365,296 tons of ore yielding 53,745,937 lb. of copper. The revenue was \$7,899,721; net operating profit, \$2,497,219; and dividends, \$1,631,504. Reserves total 80,746,973 tons averaging 2.2% copper.

WASHINGTON, D. C.

CONGESTION OF LEGISLATION THREATENS MANY BILLS RELATING TO MINES AND MINING.—THE RADIUM BILL.—MINING EXPERIMENT STATIONS.—MINERAL ON INDIAN LANDS.—LEASING AND MINE CODE COMMISSION BILLS.

Legislation in Congress is becoming so congested that the likelihood is strong that none but the more important bills will pass at this session, and therefore the minor legislation, such as new mining laws and proposals, stands little chance of reaching the President for his signature. At such times as these a slight obstruction is usually fatal. Legislation by unanimous consent is hard to effect. Of course, such bills go over to the short session, but if a disputed bill cannot obtain favorable consideration at the long session, such as the present one, its chances are very poor in the short session of three months. The proposed mining legislation is about in this boat. Those who are promoting it are naturally optimistic, but one can see from the reports of progress made that the rowing is hard.

The radium bill seems to have more of a chance than the other bills. If a vote can be reached, the bill may possibly pass the Senate. Several senators, however, oppose it on the ground that it is too wide open in character, and is, moreover, "hysterical legislation." The Taylor bill for min-

ing experimental stations, such as those in the Department of Agriculture, is to go on the House calendar with a favorable report from M. D. Foster, of Illinois, who is chairman of the House Committee on Mines and Mining. The plan involves an appropriation, and Congress may be loth to pass the bill on this account. Only as a sop to the mining interests and the desire to favor the popular chairman of the committee is the bill likely to procure an unexpected immediate enactment into law. The bill in the Senate known as S. B. 587, and relating to the disposal of coal and mineral deposits in Indian lands, has been put on the Senate calendar with a favorable report which says that the coal and deposits of other minerals in the lands which the bill will affect belong to the Indians, and the Indians should have the benefit of the proceeds from the deposits, whether such deposits are disposed of by sale or by leasing or by any other method. This, it is stated, will not be merely declaratory of the purpose of the Government to hold such deposits in trust for the Indians, but would also prevent the disposal, inadvertently or otherwise, of such deposits so as to deprive the Indians of the proceeds that are rightly theirs. The bill by Senator Walsh of Montana to encourage and promote the mining of coal, phosphate, oil, gas, potassium, and sodium on the public domain (a leasing bill) has been referred to the public lands committee. Senator Walsh made no objection. He had hoped to retain charge of his own measure as chairman of the mines and mining committee, but the public lands committee, which has been becoming a bit jealous of the inroads on its domain by the mines and mining committee, rose up to assert its prior rights, and the Senator yielded rather than stir up prejudice against his bill. The bill by Senator Smoot of Utah, providing for a commission to codify and suggest amendments to the general mining laws of the land, is to go through the Senate, according to all accounts. It has been put on the calendar. It is announced that mining engineers are for it, although believing that the commission ought to be larger than it is planned to have it. Senator Perkins, of California, has presented to the Senate, petitions of the Chamber of Mines and Oil of Los Angeles, favoring the withdrawal of mineral lands from the present boundaries of the Colorado River Indian Reservation and restoring it to entry under the U. S. mining laws.

GUADALAJARA, JALISCO

REDUCED OPERATIONS AT DOS ESTRELLAS MINES, EL ORO.—THE AGUASCALIENTES SMELTER AND ORE SUPPLIES.—SILVER FOR COINAGE.—OIL DEVELOPMENT AT TAMPICO.

Operations at the Dos Estrellas gold mines, in the Tlalpujahua district of Michoacan, for years the most important producer in Mexico, have been reduced to a great extent, and according to advices from Tlalpujahua more than 1200 men have been dispensed with. Reduced value of the ore and increased expenses, including additional taxes and direct contributions as a result of present conditions in Mexico, are given as the reasons for this step. It is understood that considerable exploration work will be undertaken. For a number of years the Dos Estrellas mines produced approximately \$1,000,000 per month, and half that sum, or \$6,000,000 per year, was paid in dividends. In the early days of Dos Estrellas, only Francisco Fournier, the French engineer who developed the mines, had faith in their possibilities, and Dos Estrellas stock was for sale on the streets of El Oro and Mexico City, and sold at ridiculously low prices. M. Fournier has been the principal Dos Estrellas stockholder since that time, and has received millions in dividends from operations.

The Aguascalientes smelter of the American Smelting & Refining Co. was forced to suspend its limited operations recently, after exhausting its supplies of coke and fuel oil,

but since that time a big shipment of coke has reached the plant, and while there is still a scarcity of fuel oil, operations have been resumed. The smelter management has raised the treatment rates, claiming that it can no longer afford to handle ore and concentrate at the former charges, and existing contracts have been broken. Due to this, and to the uncertainty of operations at Aguascalientes, some of the mining concerns that ordinarily would ship there are arranging for export shipments. The Casados Mining Co., of the Hostotipaquillo district of Jalisco, has made a shipment of high-grade ore to Swansea, Wales, and it is probable that the concentrate of the Cinco Minas Co., of the same district, will go there. The Amparo Mining Co., of the Eizatlan district of Jalisco, continues to ship its concentrate and high-grade ore to the Selby smelter in California. The Amparo dividend rate has been raised from 4 to 5% per quarter, and the disbursement to stockholders this year will be \$400,000, against \$320,000 last year.

The recent arrangement between the Huerta government and the Sociedad Afinadora de Metales, the French refining company of Mexico City, by which the silver bullion received

EL FAVOR PROPERTY, SHOWING WALL BUILT TO KEEP OUT BANDITS.

by the latter was to be delivered for coinage, and a considerable quantity of *tostones* (50-centavo pieces) turned over weekly to the mining companies supplying the silver, did not remain effective long, due to a financial hitch between the government and the refining company. Only two shipments of coin were made to the mining companies interested. Mining companies in various districts still are forced to pay a premium for much silver needed for payrolls.

A great oil development in the Tampico territory during the last few years has finally resulted in a large crop of Mexican oil companies, and at present there is much oil excitement in Mexico City and other cities of the country. Considerable money is being invested in oil stocks. The big gusher brought in recently by the Corona Oil Co., a subsidiary of the Royal Dutch-Shell, is estimated to have a capacity of 187,000 bbl. per day, making it the world's greatest well. The Casiano No. 7 well, of the Huasteca Petroleum Co., one of the Doheny subsidiaries, which was brought in in September 1910, has produced to date nearly 29,000,000 bbl. of oil, which gives it the world's record for production.

The No. 7 level of the Mololoa mine, in the Hostotipaquillo district, on the Soledad orebody, has been opened. In January this mine produced 651 tons of ore worth \$25,100, returning a profit of \$14,048 from treatment at El Favor, in the State of Jalisco.

A 20-ton concentrating plant has been ordered by La Dicha Mining & Milling Co. for the old Dolores mine, in Ixtlan del Rio district of Tepic. W. H. Hackett is manager.

General Mining News

ALASKA

A shipment of 250 tons of copper ore from the Mother Lode copper mine, near McCarthy, has been sent to the Tacoma smelter. It will average nearly 60% copper. A lot of 198 tons in April returned 59.83%, netting \$147.41 per ton, and after freight was deducted, \$24,363. A branch line from the Copper River & Northwestern railway to the mine is needed badly. The United Copper Exploration Co. has copper properties near the Kuskulina glacier, and along Porcupine creek on Copper mountain, and T. W. Lynch has arrived to conduct prospecting during the season.

FAIRBANKS

At a depth of 60 ft., Tyndall and Finn have opened 4 ft. of ore, worth up to \$1000 per ton, from their Bondholder claim at the head of St. Patrick creek. A good number of prospectors have been busy in this area.

JUNEAU

The following new electrical machinery is to be installed in mines in this district: Two 18-ton bar-steel locomotives for underground and surface haulage for the Alaska Gastineau Mining Co. These locomotives were especially designed for a low height in order to permit them entering the mine. One 5½-ton storage-battery locomotive for 30-in. gage, equipped with two V-50 motors and 68 cells of A-10 battery, for the Alaska Juneau Mining Co. These will be supplied by the Westinghouse Electric & Manufacturing Company.

KNIK

The 900 tons of Matanuska coal mined for the U. S. Bureau of Mines was delivered to a good landing above Old Knik on March 6, and is ready for shipment south for testing. J. Dalton and 10 men did this work of transporting the fuel. He estimates the cost of mining and freight at about \$65,000. The coal was mined last summer under the management of George Evans.

NOME

The annual dog-team race for the All-Alaska Sweepstakes, from Nome to Candle and return, 412 miles, was won on April 16 by Johnson in about 81 hours.

The Behring Dredging Co. recently closed a contract with the Union Construction Co., of San Francisco, for a 2½-cu-ft. close-connected bucket-dredge, to be erected on its property on the Kougarok river, where heretofore over \$750,000 has been spent for mining machinery in an unsuccessful attempt to handle the ground. Engine distillate will be used as fuel on the boat, which will be equipped with two Western gas-engines, and a gas-engine-driven electric lighting set. One of the salient features of this installation will be the arrangement of the screen and flume, by which the amount of water necessary to be pumped for washing purposes is reduced to a minimum and allowing the gold-saving tables being kept under lock and key, thus obviating the necessity of keeping a man in the flume to move the large boulders. This design is featured exclusively by the Union Construction Co. The dredge will be shipped to Davidson's landing on the Seward Peninsula this summer, and hauled over the ice during the winter. In this way everything will be on the ground ready for erection in the early spring of 1915, and practically a full season's operation will be obtained the same year.

PORT WELLS

A clean-up of the Granite Gold Mining Co.'s 7-ft. slow-speed Lane mill, from a 12-day run, about 200 tons, yielded gold worth \$8500. The mine is on Hobo bay in this district. The

ore was mined from an adit and shaft 190 ft. below the surface. The ore-shoot is 7 ft. wide in the shaft. Thirty men are employed.

ARIZONA

GILA COUNTY

(Special Correspondence.)—Two furnaces are running at the Old Dominion plant. The basic converter, which is handling all the matte from the furnaces, has made over 23,000,000 lb. of copper without any lining repairs being necessary, and it is still in good condition. The concentrator is milling up to its full capacity. In the construction department, work on two big concrete slime-thickening tanks has been completed, and a Dorr thickener installed. A pump station, to contain two 1200-gal. per minute Aldrich quintuplex electric pumps, is being cut on No. 18 level of the mine. Equipment for motor haulage on No. 12 is nearly complete, Globe, April 18.

(Special Correspondence.)—Concreting the main east shaft of the Inspiration mine is well under way, the work being started at the 400-ft. level.

Miami, April 18.

GREENLEE COUNTY

The original plans of the Arizona Copper Co.'s concentrating plant called for a capacity of 3000 tons per day; but it has been decided to increase this by another 1000 tons. The present tonnage is about 2000 per day, and in July the new plant should be finished.

PINAL COUNTY

(Special Correspondence.)—The Reymert, now being developed by the Gunn-Thompson interests, is 8 miles southwest from the Magma. It is located on a large, well defined and continuous vein, from which a good deal of silver-lead ore was extracted in early days. A 20-stamp mill remains on the property. The vein is from 10 to 60 ft. wide, is highly silicious, and its loose, leached structure indicates an oxidized zone of considerable depth. For this reason, the development of the vein wholly by hand work has not yet been productive of definite results, but it is believed that there may be a large sulphide zone beneath. Several weeks ago the shaft had reached a depth of about 350 ft., and because of the vertical position of the vein, material from the lode was being taken from the bottom. This vein material indicated that the oxidized condition of the surface virtually obtains unchanged at the depth so far reached. The superintendent, Thomas Tighe, is optimistic about the mine at depth. Because of the open nature of the large vein, former miners would select a portion containing several stringers of rich silver ore, and drive along this ore; but at the present price of silver, such work would not be profitable.

Superior, April 16.

The Magma Copper Co., at Superior, is to install nine A.C. squirrel-cage motors, totaling 267 hp. and 90-kva. transformer capacity, for operating the copper concentrating mill being built by the General Engineering Co. An interesting point in connection with this installation is that the energy for operating the motors, of Westinghouse make, will be supplied from the Roosevelt Dam power scheme.

YAVAPAI COUNTY

(Special Correspondence.)—About 100 men are examining the placer ground located east and northeast of the Hassayampa river from the 'Garden of Allah.' The area covers about 72 square miles. Past work and the prospects of good returns are encouraging.

Wickenburg, April 16.

YUMA COUNTY

(Special Correspondence.)—There has been a lively rush of miners to a gold discovery made by E. Osborne at Mineral Hill, about 20 miles northeast of this place.

Bouse, April 16.

CALIFORNIA

AMADOR COUNTY

The new tailing disposal scheme of the Kennedy company, at Jackson, is in full operation and giving satisfaction. In

TAILING WHEEL HOUSES FOR THE KENNEDY SCHEME.

another issue of this journal, full details of the plant will be given, and also the tailing problem of the district generally will be discussed.

LASSEN COUNTY

Mining around Doyle is increasing in activity. Rich ore is coming from the Lakeview claim of Truscott and McNab. The Martin claims are showing copper, lead, and silver. Those owned by Daly and Bruce were sold to Nevada people.

MARIPOSA COUNTY

(Special Correspondence.)—L. A. Schrowen, of Los Angeles, and David Upton returned from Mt. Pinoche, on the south fork of Merced river, where they have been for several days sampling the Little Wonder group of 14 gold-bearing quartz claims, owned by Messrs. Kylburg, Caterwood, and Blair. They brought in several large sacks of samples. The bonding price is \$45,000.

Clyde S. Longyear, representing the E. J. Longyear Co. of Minneapolis, Minnesota, who are manufacturers of diamond core-drills, was in Mariposa recently consulting owners of a copper property who contemplate using core-drills for determining its deposits at a depth of 2000 ft. Core-drills have been used in the Green Mountain district. David Ross, of Stockton, was in Mariposa recently, securing an extension of 60 days on his option bond to purchase a group of copper claims. There are about 600 acres of copper claims with gossan and surface indications promising a large deposit of copper. This property is situated two miles southeast of Mariposa, where there are sites for adits which will give them 600 ft. of backs. The Mariposa Mines Development Co. has taken a bond on the Dribz, Spencer San Log, and W. Y. O. D. quartz mines owned by S. J. Harris, the county surveyor; also the Breen claim owned by G. J. Bertken and the Mountain Queen and Number Three, quartz mines owned by D. E. Johnson. They will put a pump in the winze and sink on the ore-shoot, which is 20 in. wide and showing 12 in. of high-grade ore. This mine was worked by the former owners in a dilatory fashion, the walls were porphyry, and probably \$60,000 was mined from pockets.

The Original Mining Co. of Merced, which is successfully operating its mine and mill, situated below El Portal on the Merced river, under the management of Frank X. Egenhoff, has taken over two new groups of claims, the Golden Rule and Moon Stone, and have a day shift working on each group. Local stockholders at Merced think highly of the property and management. There are many other rich farming towns whose citizens could be successfully operating a good gold

mine in Mariposa county. There are plenty of good mines here awaiting intelligent development.

The Mt. Gains mine, near Hornitos, is under bond and being pumped out by Los Angeles and Denver people under the management of A. M. Gillespie. The surface equipment and machinery on this property is in good order. The Mary Harrison was pumped out and sampled last week, the samples being forwarded to San Francisco. There are seven men developing the Bondurant property near Colterville. This property is on the east or slate belt, from which millions have been mined in Mariposa county. The most notable mine on this belt in Mariposa county is the John Hite, at Hite Cove, on the south fork of the Merced river. This mine is credited with between \$3,000,000 and \$4,000,000, and while it is now idle, there is no doubt that the right man will some day open this mine and get good returns. It is 1555 ft. deep, operated by water-power, and the vein is 14 ft. wide at the 1500-ft. level. J. L. Dearborn, of Richmond, California, has become interested in the Judkins and Weston property, and has arranged to buy the 10-stamp mill from the Joshua Hendy company and settle the lumber bills accrued by the Los Angeles people in building this mill. They have 100 tons of ore which will be milled as a test. The Joshua Henry company will send a millman, and this test run will be watched with unusual interest owing to the fact that the former operators made a complete failure. Judkins and Weston are first-class miners and Mr. Dearborn is an experienced business man well up on ore treatment, and it is expected there will be an agreeable surprise in store for some of the Mariposa people when the clean-up is made. C. F. McElligott, of Princeton, is running 10 stamps on a waste dump of the Princeton mine.

Mariposa, March 26.

Some remarkable specimens of leaf gold in quartz have been found in a cross-vein at a depth of 150 ft. in the Bondurant mine, near Colterville. The other ore in the mine is 'spotty' in character. There is a mill of 10 light stamps on the property, which is owned by A. L. Adams. The Cemet Mining Co., of Los Angeles, owning a mine at Jerseydale, will start work and mill 1000 tons of ore as a test. Sampling the mine averaged \$12 per ton. The vein is from 30 to 36 in. wide, and between two adits there is estimated to be 7400 tons. The old Merced group, near Colterville, is opened to about 1000 ft. Eastern people are said to have secured an option on the claims. Lessees at the Pine Tree mine have had the following returns: 128 tons yielding \$575, 24 tons for \$365, 15 tons for \$720, and 18 tons for \$160.

NEVADA COUNTY

The North Star shaft has reached a total depth of 6000 ft. on the incline, or about 2250 ft. vertical. The first clean-up of the Golden Center mine yielded \$5000, and a shipment of selected ore was worth \$528 per ton. The Brunswick Consolidated company is to install three 100-kva. oil-insulated, self-cooled transformers of Westinghouse make.

SHASTA COUNTY

The Guggenheim interests have bonded 1400 acres of gold-bearing ground south and west of Igo, 900 acres from the Happy Valley Land & Water Co., and 500 acres from C. A. Russell and partner. The new owners are preparing to prospect the ground, with a view of putting in a dredge.

Porter and Thompson spent \$21,000 in building and installing a dryland dredge. They operated it a month or so, but it was found that the cost of operation was more than the profits. Their dredge is under attachment.

At a depth of 700 ft., and in an adit 3700 ft. long, a large electric hoist is being installed in the Gladstone mine in the French Gulch district. Mining is being done at a depth of 1100 ft. below this station.

SISKIYOU COUNTY

The Great Northern mine, on Humbag creek, is to be re-

opened by A. C. Kaiser. Rich ore is being extracted from the Carson-Kradel claim in the Oro Fino district. The Onyx jade mine, near Happy Camp, has been sold by D. C. Collier and S. Ferry to the Californite Company of San Diego.

COLORADO

EAGLE COUNTY

Developments in the Eagle district are said to be distinctly promising. The Lady Belle and South Dakota have been shipping good silver ore; lessees in the former have recently cut what is thought to be the main ore-shoot; the Lady Belle No. 4 is producing from a good vein; the Extension will soon make shipments; work has been resumed at the North Dakota; the Best Chance and Dakota Extension are busy on development, the former having opened ore; the Eagle King incline shaft is to be sunk deeper, the bottom being in low-grade ore just now; and steady prospecting is being done at the Montana.

It is reported that a mill and cyanide plant will be erected at the Lady Belle mine, there being enough ore opened to justify this step.

GILPIN COUNTY

The property of the 50 Gold Mines Corporation at Black Hawk has been acquired by a Colorado syndicate headed by John B. Selvidge. The new concern is known as the Fifty Consolidated Gold Mines Co. The claims include the Bobtail, Fiske, Gregory, Pederson, and Cook, which have been opened to 1300 ft. and have produced a large quantity of gold, silver, and copper. Extensive development is to be done by the new Company. The Continental Mines, Power & Reduction Co. has driven its Lombard adit about 3000 ft., to cut several veins. A modern 20-stamp mill is ready for work.

LAS ANIMAS COUNTY

On April 20, at Trinidad, there was a collision between coal miners and the state militia, resulting in 30 of the former being killed.

LAKE COUNTY (LEADVILLE)

This district is producing an average of 2200 tons per day of all classes of ore; of which 25,000 tons per month goes out of the camp for treatment. Good progress is being made at the new zinc smelter. With the advent of spring, prospectors are preparing to start work in the district.

From 6 to 36 in. of ore has been opened in the Little Johnny, and a carload returned 18 oz. gold per ton.

TELLER COUNTY (CRIPPLE CREEK)

A shipment of ore from the Cresson mine, worth about \$40,000, was recently sent to the smelters under an armed guard.

THE SAN JUAN

Silverton people expect a busy season this year. The Sunnyside mine has resumed work since the fire and snowslide last December. Nothing is being done at the Buffalo Boy, both sides to the dispute mentioned in this journal of July 19, 1913, being inactive. Nearby is the Intersection, which is producing 30 tons per day of ore averaging \$16.48 gold and \$3.10 silver per ton, which is treated in a 10-stamp mill. At Middleton the Hamlet mill will start in a week or so. The S. D. & G. Leasing Co. is milling ore from the Silver Lake mine at the Iowa mill. The railway to Gladstone will soon be opened.

IDAHO

BLAINE COUNTY

The Wilbert mine, on the Little Lost river, is developing into a good one. Eight feet of 35% lead ore has been opened by an adit. The mill is at present shut down.

CUSTER COUNTY

The ore deposits in the northwestern part of this county

are thoroughly described by J. B. Umpleby in *Bulletin* 539 of the U. S. Geological Survey.

SHOSHONE COUNTY

The Idora Hill mine and mill, on Sunset peak, near Wallace, is shut down owing to shortage of funds to continue work. The debt is \$30,000. The new mill at the Frisco mine is treating zinc ore during one shift per day. Copper glance has been opened in the National mine, near Mullan, which contains both native copper and native silver.

The long raise from the lower adit of the Bunker Hill & Sullivan mine, connecting with the Caledonia workings, was completed on April 15. This will greatly aid mining in the latter mine. The unit of the Bunker Hill & Sullivan mill which is being repaired for use of the Caledonia company is almost completed, and it is anticipated that operations at the mine will be commenced in a few days. Net earnings of the Interstate-Callahan company in March were \$34,000.

MONTANA

SILVERBOW COUNTY

For driving mine-ventilating fans, the Anaconda company has ordered 14 alternating-current motors, totaling 290 hp., from the Westinghouse Electric & Manufacturing Co. The Amalgamated Copper Co. will pay a dividend of \$1.50 per share on May 25. At 2400 ft. in the Tuolumne mine the shoot is 140 ft. long, showing at each end, respectively, 18 in. of 12% copper and 12 oz. silver, and 72 in. of 5% copper and 12 oz. silver ore.

During March the Butte-Duluth leaching plant produced 75,000 lb. of copper. The new 1000-ton per day crushing plant may be completed in 30 days.

MISSOULA COUNTY

After several years of litigation, Spokane men are planning to reopen the old Amador mine at Iron Mountain, in the east Coeur d'Alenes. It is said that about \$750,000 was spent for a 50-ton smelter, 10-mile railway, large water-power plant, and developing an orebody to 750 ft. Stock boomed to \$4 per share, heavy assessments were made, and litigation resulted. A concentrating plant may be erected. E. V. Lambert is president of the company.

NEVADA

ESMERALDA COUNTY

There is more activity in the Cuprite district, 14 miles south of Goldfield, than for some time past. The Jupiter claims have given good assays of copper-silver ore. Other claims being prospected are those of the Kurien-Smith-Evans syndicate.

HUMBOLDT COUNTY

At a depth of 260 ft. from the surface, high-grade ore has been opened in the Buckskin National mine.

LINCOLN COUNTY

The mines at Pioche produced about 2000 tons of ore worth \$30,000 last week. The Prince Consolidated contributed 1400 tons, while the Mendha-Nevada, Providence, Exploration lease, Day-Bristol, Amalgamated Pioche lease, Oregon Short Line lease, and Nevada Mark made up the balance.

MINERAL COUNTY

The Goldfield Consolidated Mines Co.'s option on the Aurora Consolidated's mines expired on April 18, and no business resulted, according to Jesse Knight of Utah.

NYE COUNTY

The Pioneer Consolidated Mines Co. will install a 6-ft. Huntington mill in its 10-stamp mill in the Pioneer district. According to the consulting engineer, J. K. Turner, the present plant is treating 30 tons of ore per day with 82% recovery. The slime contains \$2 in gold per ton, and efforts are being made to increase the saving to 90%. Twelve feet of

ore is being mined in a raise above 256 ft. The annual report of the North Star Mining Co. for 1913 shows the following: Development, 2963 ft., at \$6.76 per foot; ore mined, 3225 tons, value \$58,966; mining costs, \$2.56 per ton; sinking, \$22.72 per foot; and net profits, \$45,845. The American Carrara Marble Co., of Carrara, sent a carload of marble, containing 200 cu. ft. to Los Angeles. This is its first shipment. The Tonopah Extension company's revenue in February was \$48,081, and expenses \$40,070. March returns are as follows: Belmont, 15,294 tons, yielding 340,878 oz. bullion and a profit of \$153,611; Tonopah Mining, 11,793 tons, yielding 227,375 oz. bullion, 126 tons of concentrate, and a profit of \$128,120; Jim Butler, 2870 tons for a profit of \$34,580. A tube-mill head broke at the West End mill last week, resulting in a shut-down for 4½ days.

TENNESSEE

POLK COUNTY

(Special Correspondence.)—F. R. Carter, of Chattanooga, who owns 160 acres of land, presumably copper bearing, about

COPPER DEPOSITS AT DUCKTOWN. THE ARROWS INDICATE DIP OF THE LODES. (AFTER U. S. G. S.)

a mile northeast of the Ducktown Copper, Sulphur & Iron Co.'s plant at Isabella, has formed an exploration company and is prospecting the property by diamond-drilling. No results have yet been published. The property is only about a half-mile southeast of the East Tennessee mine of the Ducktown company, but it may be too far to the east to be within the known ore-bearing zone.

Ducktown, April 15.

UTAH

BEAVER COUNTY

The Sheep Rock mill is to be enlarged by the Sheep Rock Leasing, Mining & Milling Co. The March return was gold worth \$3000. The main shaft of the mine is down 200 ft. A recent sampling of the ore opened returned good assays.

UTAH COUNTY

High-grade gold-silver ore is being mined from 700 ft. in the Grand Central mine at Tintic, that at present averaging 2 to 4 oz. gold and 80 to 200 oz. silver per ton with a little lead and copper. An option has been taken on a tailing dump of over 200,000 tons, at the Eureka Hill mine by Brayton Campbell and C. M. Dull. A cyanide plant will probably be erected to treat 200 tons per day. The tailing assays 5 oz. silver, 0.05 to 0.06 oz. gold, 1% lead, and 0.01% copper.

SALT LAKE COUNTY

The Utah Copper Co., at its Magna mill, is to install four 15-hp. slow-speed vertical D.C. motors for direct connection to agitators used in experimenting with the oil-flotation process. This is a new application especially developed by the Westinghouse Electric & Manufacturing Co. after considerable testing. About 50 tons of low-grade copper ore, containing a good percentage of iron, is being mined daily from the Commercial mine at Bingham. A raise from the Niagara adit level to the old workings of the Commercial will greatly improve ventilation.

WASHINGTON

CHELAN COUNTY

(Special Correspondence.)—The Golden Eagle company's mine and mill has been leased by F. Le Roi Thurmond, who will start operations at once. It is proposed to change the name of Blewett to Phoenix.

Blewett, April 7.

FERRY COUNTY

Extensive development of the Anchor, Curlew, and Panama groups of 19 claims, situated two miles north of Curlew, is to be done by the Phoenix Gold & Copper Mining & Milling Co. The main adit is in 900 ft. Ore has been opened in three places in the first 500 ft. of the lower adit, and a large vein 40 ft. wide was opened at 500 ft. At 820 ft., 5 ft. of shipping and 20 ft. of milling ore was also cut. At about 1500 ft. another vein should be opened.

CANADA

According to the manager of the Canadian Klondyke company, Charles Boyle, 300 to 400 men, about the full complement for the operating season, are now employed at the various properties. No. 4 dredge was expected to start about March 24, and the others soon after. The Yukon Gold Co. has begun preliminary work for the season. The annual report of the territorial assayer at Whitehorse, William Sime, covers the twelve months up to March 1, 1914. A total of 885 samples were sent in from 13 different districts, and 1082 determinations made. The most development done in any lode mine was in the Pueblo, 7 miles from Whitehorse, and owned by the Atlas Mining Co. From the 6, 130, and 200-ft. levels, 36,662 tons of copper ore was sent to the smelters. The shaft is down 365 ft., and 28 prospect holes were drilled totaling 3796 ft. An average of 100 men was employed. The Humper claims in the Windy Arm district, Whirlwind, Tally-Ho, Buffalo Hump in the Wheaton River district, and at several in the Mayo and other districts, were actively prospected.

The Yukon Gold Co. has taken options on eight or nine miles of ground along the Sixtymile valley, lying in a continuous tract, mostly between the mouth of Glacier and the mouth of Twelvemile creeks. Two drills are being taken out over the winter road to prospect the ground immediately. C. A. Thomas is manager for the Company.

COSTA RICA

February operations at the Abangarez Gold Fields mine resulted in the treatment of 5323 tons of ore, yielding bullion worth \$29,007. There was a loss of \$20,246, making the \$8,761 for the two months of the current year.

Personal

THEODORE HOOVER has gone to Burma.
ROSS B. HOFFMAN is back from London.
WILLIAM DE L. BENEDICT is in San Francisco.
H. L. HOLLISTER was in San Francisco this week.
LEWIS A. WRIGHT was in San Francisco last week.
C. W. PURINGTON has returned to London from Italy.
LIONEL LINDSAY of San Francisco leaves for London, May 1.
WILLIAM KNOX returned to San Francisco from London this week.
FRED J. SIEBERT of Reno, Nevada, will leave soon for Santiago de Chile.
H. B. BARLING was at Salt Lake City last week on his way to Ely, Nevada.
J. H. MACKENZIE visited the Buckskin National Gold Mining Co.'s property recently.
REIJI KANDA is examining a gold deposit in Korea for the Hasami Gold Mining Company.
DAVID HOFFMAN has returned to Butte, Montana, after an absence of two years in the Congo.
Mail for CHARLES NOURSE, L. C. MOTT, and F. C. MOORE is waiting for American address at our office.
J. D. HUBBARD of Chicago, vice president of the Goldfield Consolidated Mines Co., is in San Francisco.
J. H. HARTLEY, of Berkeley, California, is examining properties in Plumas and Sierra counties, California.
J. A. UDDEN has been visiting Alabama, Pennsylvania, and other eastern states, but will soon be back at Austin, Texas.
VICTOR ZIEGLER has accepted a position as assistant professor of geology and mineralogy at the Colorado School of Mines.
E. F. GRAY, general manager of the Consolidated Copper Mines Company, at Ely, was at Salt Lake City last week on his way to London.
Z. B. HARTLEY, formerly with the Aguacate Mines Co. of Costa Rica and the Cacamuya Mines Co. of Honduras, sailed for Ecuador, S. A., last month.
N. M. WADE has been appointed general manager, and JOHN H. EGGERS superintendent, for the Rochester Mines Co., Rochester Weaver M. Co., and Nenzel Crown Point M. Company.
GEORGE H. GARREY, recently connected with the American Smelting & Refining Co. as chief geologist, has opened an office as consulting mining geologist and engineer at 115 Broadway, New York City.
B. BRITTON GOTTSBERGER, general manager of the Miami copper mine, gives the following names as members of the staff in 1913: F. W. MACLENNAN, assistant manager, in charge of mining; F. W. SOLOMON, mill superintendent; and RALPH P. YERXA, assistant mill superintendent.
Among those registered at the New York convention, American Electro-Chemical Society, were: LAWRENCE ADDICKS, C. L. BRYDEN, A. S. DWIGHT, CARL HERING, J. B. HERRESHOFF, L. D. HUNTOON, W. MCA. JOHNSON, R. L. LLOYD, D. A. LYON, H. C. PARMELEE, CHARLES L. PARSONS, THOMAS T. READ, G. A. ROUSH, W. O. SNEILING, H. N. SPICER, BRADLEY STOUGHTON, G. C. STONE, and JOSEPH STRUTHERS.
COLUMBIA UNIVERSITY will celebrate the fiftieth anniversary of the founding of the School of Mines on May 28 and 29. There will be a great gathering of engineers. On the morning of May 29, in the gymnasium, there will be a meeting at which honorary degrees will be granted and there will be talks on modern engineering by well known engineers. In the afternoon will occur the first lecture in the 'Chandler Foundation' by a distinguished chemist, and the celebration will close at night with a banquet at the Waldorf Astoria, where eminent alumni will speak.

Society Meetings

| Name. | Date. |
|--|--------------|
| MAY | |
| American Iron and Steel Institute | 22 |
| Chemical, Metallurgical and Mining Society of South Africa, Mining Exhibition, Johannesburg..... | 19-29 |
| Geological Society of America (Cordilleran Section), Seattle | 21-23 |

Schools and Societies

The CHEMICAL, METALLURGICAL, AND MINING SOCIETY OF SOUTH AFRICA will visit the De Beers diamond mines, at Kimberley, early in July.
The MICHIGAN COLLEGE OF MINES held a class-day address to graduates of 1914 on 'Mining Coal Above the Arctic Circle,' by the Hon. John Munro Longyear, on April 16. Work at the mines on Spitzbergen, north of Europe, was covered by the speaker.
The CHICAGO ENGINEERS' CLUB had a membership of 386 on March 1, 1914, of whom 301 are resident members. The revenue during the year ended February 28, 1914, was \$31,671, including \$1772 from the previous year. The term ended with a balance of \$543. A number of lectures and excursions were held.

The Metal Markets

LOCAL METAL PRICES

San Francisco, April 23.

| | |
|--|------------|
| Antimony | 9 — 9½ c |
| Electrolytic copper | 15½—15¾ c |
| Pig lead | 4.05— 5.00 |
| Quicksilver (flask) | \$38.50 |
| Tin | 40½—42 c |
| Spelter | 6½— 6¾ c |
| Zinc dust, 100 kg. zinc-lined cases, 7½ to 8 c. per pound. | |

EASTERN METAL MARKET

(By wire from New York)

NEW YORK, April 23.—All metal markets are quiet and weak. Copper has declined every day, lead remains the same, while spelter is slightly below last week's quotation. Copper stocks continue to puzzle speculators. Amalgamated copper is the strongest stock on the Exchange at present. American Smelting & Refining shares rose from 65 to 66 on news from Mexico. It is said that the Anaconda Copper Mining Co. has offered to purchase the assets and business of the International Smelting & Refining Co., and to exchange its stock for stock of the International on a basis of 3.33 shares of Anaconda for one share of International, upon condition that the International will immediately call a special meeting of stockholders to take action upon the proposal to sell its assets to the Anaconda company and liquidate. The International has a smelter in Utah and is erecting another in Arizona. Its present indebtedness is \$9,000,000, and this would be increased to \$11,500,000 by the new plant, necessitating the issue of stock to clear the debt and provide additional capital. Tin is irregular at 35.15 to 35.60c. per pound. The trouble in Mexico affected stocks in London and Europe, there being heavy trading. Bar silver is steady at 26.93d. per ounce. Copper and tin were firm at £61 6s.3d. and £161 5s. per ton respectively.

SILVER

Below are given the average New York quotations in cents per ounce, of fine silver:

| Date. | | Average week ending | | |

| June | 59.03 | | Dec. | 57.73 |

Pixley and Abell, of London, writing on April 2, state that they are glad to be able to announce that the whole of the silver, amounting to about \$14,500,000, which was taken over by the syndicate formed for that purpose on the failure of the Indian Specie Bank early in last December, has now been sold. Had this syndicate not been formed, and had all this silver been thrown on the market by forced sales, the result would have been disastrous not only to producers and others connected with the metal, but to all merchants trading with China. Without the huge holdings of the Indian Specie Bank, the market has during the past four months acquired a healthier and more normal tone, and, with a very small speculative account open, the general position is far sounder than it has been for some years past.

LEAD

Lead is quoted in cents per pound or dollars per hundred pounds New York delivery.

| Date | | | Average week ending | |
|-------------------|------|--------------|---------------------|--|
| Apr. 16..... | 3.80 | Mch. 11..... | 4.00 | |

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

| Week ending | | Apr. 9..... | 39.00 |
|-------------------|-------------|-------------|------------------|
| Mch. 26..... | 39.00 | " 16..... | 39.00 |

Zinc sulphide ores, at Joplin, Missouri, are now selling for \$35 to \$40 per ton, basis of 60% metallic zinc, compared with \$40 to \$44, basis, for the corresponding period of 1913. Lead ore brings \$45 per ton, basis of 80% metallic lead, compared with \$52.50 a year ago. Cadamine brings \$16 to \$19, basis of 10% metallic zinc, compared with \$19 to \$20 a year ago. The average shipments of sulphide ores for 1914, to date, are 1920 tons per week, cadamine 329 tons, and lead 910 tons. The average weekly valuation of all ores is \$240,000.

TIN

New York prices, control in the American market for tin, since the metal is almost entirely imported. San Francisco quotations average about 5c. per lb. higher. Below are given average monthly New York quotations, in cents per pound:

| Monthly averages. | | | | |
|-------------------|-------|-------|------------|-------|
| | 1913 | 1914 | | 1914 |
| Jan. | 50.45 | 37.85 | July | 40.70 |
| Feb. | 49.07 | 39.76 | Aug. | 41.75 |
| Mch. | 46.95 | 38.10 | Sept. | 42.45 |
| Apr. | 49.00 | | Oct. | 40.61 |
| May | 49.10 | | Nov. | 39.71 |
| June | 45.10 | | Dec. | 37.55 |

Silver output of the Kongsberg mines, Norway, during the year 1912-1913 was 8459 kg. (270,680 oz.) fine metal, and 1137 kg. (36,180 oz.) in ore, the whole worth \$183,000.

Pig iron production of the United States in March was 2,317,867 tons.

UNITED STATES OF THE U. S. Steel Corporation on March 31 were 1,653,255 tons, against 7,468,556 tons a year ago.

PYRITE AND SULPHURIC ACID PRODUCTION IN 1913

The production of pyrite in the United States in 1913, according to W. C. Phalen of the U. S. Geological Survey, was 341,338 long tons valued at \$1,286,084. For 1912, the output amounted to 350,928 long tons valued at \$1,334,259, a decrease for 1913 in quantity of 9590 long tons and in value of \$48,175. The production in the leading states—Virginia and New York—diminished slightly; in California there was an increased production; and in Wisconsin, the output also continued to increase. The imports of pyrite for consumption during the calendar year 1913 were 850,592 long tons valued at \$3,611,137. These figures show a notable decrease in quantity. According to actual returns for the year 1913, the production of sulphuric acid in the United States was 3,538,980 short tons of 50° acid, valued at \$22,366,482. This output does not include a small amount of fuming acid, but does include by-product acid, that is, acid obtained in the smelter industry. The acid produced at copper and zinc smelters in 1913 amounted to 790,296 short tons of 50° acid, valued at \$4,346,272. These figures are final, so far as the Survey's present information goes.

MINERAL PRODUCTION OF TASMANIA IN 1913

The past two years' production of this Australian state shows the following:

| Product. | 1913. | 1912. |
|----------------------|---------|---------|
| Bismuth..... | £1,627 | £2,646 |
| Coal..... | 25,367 | 24,568 |

PETROLEUM PRODUCTION of the Dutch East Indies, mainly Borneo and Sumatra, was 1,503,660 tons in 1913.

Company Reports

SUDAN GOLD FIELD COMPANY, LTD.

This Company has a large concession in the Sudan, 30 miles of light railway, a 10-stamp mill and cyanide plant. Development in 1913 totaled 5304 ft. Ore reserves are estimated at 42,862 tons, an increase of 15,862 tons. About 1600 tons of high-grade ore was opened in a folded portion of the vein. The plant treated 17,049 tons of ore yielding \$190,000. The year's profit was \$29,000, from which \$24,000 was written off for depreciation and other work.

BARRAMIA MINING & EXPLORATION, LTD.

This Company's property is situated between the River Nile and the Red Sea in upper Egypt. The mine is characterized by small rich pockets of ore, one in 1913 producing 59 tons with 480 oz. gold, and another 84 tons yielding 1192 oz.; but there were few opened during the past year. Ore reserves are estimated at 16,500 tons averaging \$10 per ton. The mine is opened to 503 ft. below the adit level. The 10-stamp mill crushed 4300 tons in 1913, yielding gold worth \$85,000. After deducting royalty, the profit was \$15,000, and a dividend of \$11,500 was paid.

CORDOBA COPPER COMPANY, LTD.

This Company operates in Spain, and has a complete reduction plant, including the Murex magnetic process. In 1913, development totaled 12,955 ft., and ore reserves show an increase, now amounting to 206,489 tons of 3% ore. At 1410 ft., the lowest level, higher grade ore has been opened than above. The shaft is being sunk to 1545 ft. Ore mined amounted to 119,069 tons, yielding 3500 metric tons of blister copper. Sales realized £231,451, and the net profit was £83,321. Dividends totaled £40,000. Results were considerably above those of the previous term.

RIO TINTO COPPER COMPANY, LTD.

During 1913 this great mine in Spain produced a total of 1,859,571 tons of 2.19% copper ore. Metal output at the mines was 21,062 tons, while the total sent to market as copper and in pyrite was 36,320 tons, or 81,356,800 lb. The net profit was £1,673,372, of which £1,487,500 was paid in dividends, and £185,872 was carried forward to the current year. Strikes interrupted the work, reducing the ore mined by 547,398 tons, and copper yield by 3500 tons. The average price received for the metal was £68 5s. 9d., against £73 1s. 3d. in 1912. Shareholders got 75s. per share instead of 90s. for the previous term.

RICO-WELLINGTON MINING COMPANY

This Company operates at Rico, Dolores county, Colorado, with headquarters at Provo, Utah. The report for 1913 shows that the remodeling of the Pro Patria mill was completed, with an auxiliary power-plant. Since starting it, 5178 tons of lead-zinc ore has been milled, with 92% extraction. Development totaled 4132 ft., making 12,963 ft. to date. A complete survey was made of the surface of the claims, and this has been checked with the mine workings, and will help underground work. The physical condition of the mine has been improved, and the future is encouraging. Besides the lead-zinc ore, there was produced 786 tons of lead and 4804 tons of copper ores. Ore sales realized \$152,271. Costs totaled \$5.83 per ton.

BROKEN HILL SOUTH SILVER MINING COMPANY

The second half-year's work of this Australian company enabled two dividends, amounting to £140,000, to be paid, and a balance of £142,523 carried forward. Development in

the mines totaled 9036 ft., including 4317 ft. of diamond-drilling. Filling distributed underground amounted to 54,951 cu. yd. at a cost of 80c. per yard of filling, and 25c. per ton of ore mined. The 725-ft. level contributed 12.6% of the 170,080 tons of ore raised; 6% from 825 ft., 33.5% from 970 ft., 40.2% from 1070 ft., and some from 625 and 1170 ft. Ore reserves above 1170 ft. are 3,350,000 tons. The mill treated 168,957 tons averaging 14.7% lead, 7.3 oz. silver, and 14.5% zinc, according to the report of the manager, W. E. Wainwright. The revenue from all sources was £354,786. During the period, the rainfall was 3.93 in., and water consumption 30,107,000 from various sources. Details of costs and other work will be given in another issue of this journal. There were 1387 men employed.

ONTARIO SILVER MINING COMPANY

This Company operates at Park City, Utah, and the report deals with work done in 1913. All of the development consisted of opening and prospecting old stopes and adjacent ground on and above the 1500-ft. or drainage level. A good deal of ore was opened in one of the three stopes. Connections have been made between this and the 1500 to the 1100-ft. levels. Ore was to have been shipped to the Daly West mill, but it was destroyed by fire at the end of the year, and work will not be resumed to any extent for several months. Ore mined was 1184 tons, returning \$16,359. The Mines Operating Co. has a lease on part of the mine above the 900-ft. level, and last year's work was not very satisfactory. The Ontario company's revenue was \$47,324, and expenditure \$49,011. Cash assets total \$338,678.

SENECA-SUPERIOR SILVER MINES, LIMITED.

The annual report of this Cobalt company contains the following information for 1913: Development totaled 5653 ft., and 4200 cu. ft. of stations, according to R. H. Lyman, the manager. The No. 2 shaft was sunk to 200 ft., affording good ventilation. On No. 3 and 4 levels the east and west drifts were driven 270 and 210 ft. respectively on the vein. A cross-cut at 100 ft. depth opened high-grade ore. The consulting engineer, W. E. Segsworth, states that there are four levels opened in rich ore, and on No. 2 level, 440 ft. has opened 3 in. of 3500-oz. ore; No. 3 level averages 2300 oz. per ton over 2½ in.; while at 334 ft., or No. 4 level, the vein is 1½ in. wide averaging 960 oz. per ton. Ore reserves contain about 3,460,000 oz. silver. The output during the past 11 months was 1,085,774 oz. The cost was 13.2c. per ounce, of which 6.92c. was for mining; 5.58c. for surface, and 0.7c. for depreciation. The profit for the year was \$288,954, of which \$263,136 was paid in dividends. The balance carried forward, including that brought forward, was \$85,290.

AMERICAN ZINC, LEAD & SMELTING COMPANY

This Company operates mines at Joplin, Missouri; Mascot, Tennessee; and in Wisconsin, and zinc smelters at Caney and Dearing, Kansas, and at Hillsboro, Illinois. The report covers the year 1913. The president, H. S. Kimball, reported that the condition of the zinc industry was extremely unsatisfactory. Average prices of spelter at St. Louis in 1912 and 1913 were 6.93 and 5.5c. per pound respectively. At the beginning of 1913 the Caney and Dearing smelters were operating at 83% capacity, and the Hillsboro had just been started. The stock of ores at these plants was 11,506 tons, costing \$500,669, being purchased during the period of high prices in 1912. This stock was written down at a heavy loss. No profits resulted from the Hillsboro smelter for many reasons. A falling-off in demand for spelter caused an accumulation of stocks at all plants. In June 1913 the Kansas plants were reduced to 33% capacity, and shut down in December. The Joplin mines are low grade, and could only be operated at part capacity, against a good profit made in 1912. The Wisconsin mines, in which the Company holds 60% interest,

made a fair profit. Developments in the Tennessee mine were satisfactory; and during the last quarter of 1913 the mill treated over 1000 tons of ore per day. The tailing finds a ready market for railroads and farms. The year resulted in a loss of \$304,630, though a dividend of \$85,600 was paid. Cash and liquid assets total \$1,709,870, and liabilities \$2,061,145, apart from property account and capital stock.

THE WOLFRAM MINING AND SMELTING COMPANY, LTD.

This Company owns 11 concessions, with an area of 1257 acres, and equipment, situated about five miles from Silvares in the province of Beira Baixa, district of Astello Branco, Portugal. The report for the year ended September 30, 1913, gives the total amount of ore broken as 22,909 tons. Shipments realized \$120,000 less than in the previous year, due to a slight decline in the output, owing to flooding during the greater part of the year, of No. 10 vein at Panasqueria, where the richest ore is recovered. Another reason was the presence of tin in ore mined at Barroca Grande and Panasqueria South, which, up to the time of closing the accounts, could not be dealt with. A quantity of tin and wolfram concentrates accumulated and it became necessary to purchase a magnetite separator for the separation of these two minerals. This machine was put into commission during the latter part of the last month of the financial year and is working satisfactorily. The balance available for distribution was \$34,000, out of which a dividend of 5% for the year, was paid on January 31, 1914.

SHANNON COPPER COMPANY

The mines and reduction works of this Company are at Metcalf and Clifton, Greenlee county, Arizona, and the report covers the 16 months ended December 31, 1913. The general manager, J. W. Bennie, states that development totaled 13,600 ft. There were no new developments during the year at the Shannon mines proper. An important discovery, however, was made at one of the Company's outside claims, known as the Alaska mine, about half a mile from the Shannon mines. The discovery was made by the Arizona Copper Co. through one of its mines which adjoins the Alaska. As far as developed, the ore is 30 ft. wide, averaging for the full width over 8% copper. Although this new shoot is of important size, and will probably furnish a substantial tonnage of high-grade ore, more development will be necessary to determine its extent or value. At the other outside claims, from which the ore shipped averaged much lower in copper this financial year, as compared with the preceding year, higher-grade ore is again showing in the lower workings, which will, in the near future, tend to increase the average copper yield of the shipments from that property.

The Company is still carrying on its leaching experiments, and, although encouraging, the process cannot yet be considered commercially a success. It is hoped that leaching in some form will become adaptable, not alone in treating the Shannon tailing, of which there are over a million tons containing over 20 lb. of copper per ton, but also in treating at a profit from one to two million tons of semi-oxidized ore carrying 2 to 2½% copper, which can be mined from the Shannon Hill at a low cost.

The mines at Metcalf produced 364,584 tons of ore, of which 361,084 tons was treated, with 73,223 tons of ore from outside properties, yielding 18,793,724 lb. copper, 3412 oz. gold, and 169,197 oz. silver. Net profits were \$476,440, from a revenue of \$3,153,412 and profit of \$33,829 from the Shannon Arizona Railway Co. A dividend of \$150,000 was paid in January 1913. Net current assets over liabilities are \$381,236, exclusive of \$284,000 railway bonds purchased. Costs were higher than before by 20c. per ton. There were no changes at the smelter. Basic converters have been used for nine months during the term.

Decisions Relating to Mining

NO TITLE TO WATER UNDER MINING LOCATION

The location of a mining claim on land in which a spring arose will give the locator no claim to the water flowing from the spring in a natural channel as against an appropriator; for title to such flow in the state of Nevada can only be acquired by appropriation and application to a beneficial use.

Campbell v. Goldfield Consolidated Water Co. (Nevada), 136 Pacific, 976. December 12, 1913.

IMPROPER VERIFICATION

Verification of an application for patent cannot be made outside of the land district wherein the claim sought to be patented is situated, and a notary public who is also acting as attorney for the applicant in the patent proceedings is disqualified to attest such verification. Entry will be denied for non-compliance with these rules.

Home Mining Company (Land Department) 42 Land Decisions, 526. November 12, 1913.

MINING CLAIM—DEFECTIVE PATENT PROCEEDINGS

Where the notice of an application for patent under mining laws as published and posted, embraces a tract not covered by the application, the notice and all proceedings had thereon are null and void as to that tract; and the defect cannot be cured and the entry permitted to stand by subsequent amendment of the application to include the omitted tract.

Pocatello Gold and Copper Mining Co. (Land Department) 42 Land Decisions, 550. November 5, 1913.

MINERAL SURVEY—TIE LINE—TWO-MILE LIMIT

Paragraph 135 of the mining regulations contemplates that each individual claim of a contiguous group embraced in the same survey shall be connected with a public survey corner of the United States location monument not more than two miles distant; and where only one claim of such group is connected to a public survey corner within the two-mile limit, and the remainder are connected by tie-lines more than two miles in length, an entry allowed for such group may be permitted to stand only as to the claim within two miles of the public survey corner and will be rejected as to the others.

Lloyd Searchlight Mining and Milling Co. (Land Department) 42 Land Decisions, 485. September 8, 1913.

SURFACE AND MINERAL TITLES—ADVERSE POSSESSION

The surface of the earth and the minerals underneath the surface may be severed by a deed, or reservation in a deed, and when so severed they constitute two distinct estates. The mineral interests being part of the realty, the estate in them is subject to the ordinary rules of law governing real property. The presumption that the party having possession of the surface has the possession of the subsoil containing the minerals does not exist when these rights are severed. The owner of the surface can acquire no title to the minerals by exclusive and continuous possession of the surface, nor does the owner of the minerals lose his right or his possession by any length of non-user. He must be disseized to lose his right and there can be no disseizin by any act which does not actually take the minerals out of his possession. The owner of the surface can acquire title against the owner of the minerals underneath by no acts or continuous series of acts that would not give title to a stranger.

Hoilman v. Johnson (North Carolina), 80 Southeastern, 249. December 10, 1913.

This gives the results of researches on cobalt and cobalt alloys, conducted at Queen's University, Kingston, Ontario, and may lead to the recovery of these minerals from ores at Cobalt.

MINERAL RESOURCES OF THE UNITED STATES, 1912. Part I. Metals. P. 1079. Ill, index. U. S. Geological Survey, Washington, 1913. This volume includes details of metal production which were published in pamphlet form during the past year and were extensively quoted in this journal from time to time. The authors who contributed are as follows: E. W. Parker, W. T. Thom, J. P. Dunlop, E. F. Burchard, D. F. Hewett, H. D. McCaskey, B. S. Butler, C. E. Siebenthal, A. H. Brooks, V. C. Heikes, C. G. Yale, C. W. Henderson, C. N. Gerry, W. C. Phalen, Frank L. Hess, J. S. Diller, and David T. Day.

U. S. Bureau of Mines publications, Washington, 1913 and 1914:

REPORT of the Director of the Bureau, Joseph A. Holmes, for the year ended June 30, 1913. P. 118. Map. This volume deals with the work of this department since its establishment, and progress of investigations during the past fiscal year. These covered mine-rescue work, saving mineral waste, mine explosions, fuels, petroleum, gas-producers, the laboratories, smelter fume, electric smelting of ores, the staff, and many other subjects, which are published in the technical press from time to time.

UTILIZATION OF PETROLEUM AND NATURAL GAS IN WYOMING. Preliminary report by W. R. Calvert. Also a discussion on the 'Suitability of Natural Gas for Making Gasoline,' by George A. Burrell. Technical paper 57, petroleum technology 13. P. 23.

PRODUCTION OF EXPLOSIVES IN THE UNITED STATES, 1912. Compiled by Albert H. Fay. Technical paper 69. P. 7. A table from this paper was published last week.

PERMISSIBLE EXPLOSIVES. By Clarence Hall. Technical paper 71. P. 12. Contains tabulated matter showing explosives tested prior to January 1, 1914.

COAL-MINE FATALITIES IN THE UNITED STATES. December 1913. With revised figures for preceding months. Compiled by Albert H. Fay. P. 28. There were 425 more men killed during 1913 than in 1912.

THE SAMPLING AND EXAMINATION OF MINE GASES AND NATURAL GAS. By George A. Burrell and Frank M. Seibert. Bulletin 42. P. 116. Ill., index. Describes the apparatus and methods used in this important work. The chemistry of these hydro-carbons is somewhat complex.

HYDRAULIC MINE FILLING. Preliminary report on its use in the Pennsylvania anthracite fields. By Charles Euzian. Bulletin 60. P. 77. Ill.

ELECTRIC SWITCHES. For use in gaseous mines. By H. H. Clark and R. W. Crocker. Bulletin 68. P. 38. Ill. The design and use of switches in such mines is very important, and details are given of tests made.

Industrial Progress

CHALMERS & WILLIAMS have taken a contract to build a large modern concentrator for the Daly West at Park City, Utah.

THE CENTRAL FOUNDRY Co. has issued a special booklet descriptive of the valve service and roadway boxes made by that firm.

The MOUNTAIN COPPER Co. will use two 8 ft. by 36 in. cyl. herringbone-gear driven Hardinge mills in the new concentrator at Keswick in Shasta county, California.

A 'Manual of Electrical Testing' has been issued by the WAGNER ELECTRIC MFG. Co. which describes the instruments, sources of error, and methods of testing alternating and direct current motors, generators, and transformes.

The CHICAGO PNEUMATIC TOOL Co. bulletins for February and March are devoted to descriptions of the 'Chicago Slugger' drill, the Duntley electric tools, and the Duntley Electric sensitive drilling stand, well known specialties of this firm.

The DEISTER MACHINE Co. catalogue of concentrating machinery now available, contains descriptions and illustrations of both the single and double deck concentrators made by this Company, and the multiple deck tilting slimer and the cone baffle classifier recently put on the market.

THE NATIONAL TUBE Co. is distributing bulletin No. 11-B, the history, characteristics, and advantages of 'National' pipe; and special circulars on the differences between iron and steel boiler tubes, and a discussion before the Boilermakers' Association committee on iron versus steel tubes.

Catalog 'D' of the ENGLISH IRON WORKS contains complete descriptions of the various Sampson hoists made by that firm in both large and small units, steam or electric driven. It also contains useful tables of horse-power required for lifting various loads, and rules for finding horse-power.

The Bearing, a little monthly published by the ALBANY LUBRICATING Co., devotes its March number to lubrication in connection with mining machinery. A number of detailed statements are given of tests on the relative efficiency of machine oils and Albany grease at various European plants, which show a marked saving in favor of the grease.

THE LIDGERWOOD MFG. Co. reports that Charles H. Locher has handled 6,235,000 cu. yd. of material with Lidgerwood cableways while connected with various contracting firms as partner. This represents a mass three times as large as the concrete placed by Lidgerwood cableways in the Gatun locks at Panama, the largest mass of concrete in existence.

The Isthmian Canal Commission has awarded to the INGERSOLL-RAND Co. the contract to furnish three large direct-connected electrically driven air-compressors of the duplex type, embodying the new Ingersoll-Rogler valve. The combined capacity of these units will be 10,000 cu. ft. They will be placed at the Balboa shops, where the air will be used for general repair work in the shops and also on the new dry dock.

The A. S. CAMERON STEAM PUMP WORKS announces the following assignment of managers to the branch houses: Birmingham, Ala., American Trust Bdg., H. M. Perry; Chicago, Ill., Peoples Gas Bdg., M. P. Frutchey; Cleveland, Ohio, Williamson Bdg., W. A. Armstrong; Duluth, Minnesota, Providence Bdg., S. H. Hill; Houghton, Mich., Thomas F. Lynch; Knoxville, Tenn., Holston Nat'l Bank, L. F. Thompson; Los Angeles, Cal., W. A. Townsend; Philadelphia, Pa., Arcade

Bdg., Phil. Weiss; Pittsburgh, Pa., Farmers' Bank Bdg., W. B. Brendlinger; St. Louis, Mo., 300 N. Broadway, A. A. Bonsack; Seattle, Wash., Colman Bdg., R. W. Douglass.

The LINK BELT Co. is now distributing a data book designed to enable users of power to select the correct silent chain drive for their work and to figure exact costs from the price lists published in the book. Besides engineering tables of great value in this connection, the book describes and illustrates many uses of the silent chain. Link-Belt silent chain is a series of links connected by joints which consist of segmental case hardened bushings and case hardened steel pins. The chain is held to be as flexible as a leather belt and as positive as a gear. Its rated efficiency is 98.2% on actual test. It is claimed that it will transmit any amount of power quietly. Over 200,000 installations, we understand, were drawn upon for the information contained in this data book, which may be obtained free from the Company.

The Nome Tramway

In *Leschen's Hercules* for April there is an interesting description of the wire rope tramway used for unloading freight and passengers at Nome, Alaska, and based upon notes furnished by A. H. Kellogg, manager for the John J. Sesnon Co., which owns and operates the tramway. The description in part follows.

Nome lies on the beach of the Bering Sea, but absolutely unprotected from the many storms that occur there during the open season, which is about from June 10 to October 31, and moreover, there are at times strong northerly and north-east winds which reach the velocity of gales. These winds blow the water a great distance out, causing extremely low water and making it absolutely impossible for lighters to get to shore. Owing to the fact of Nome being an unprotected harbor, and Bering Sea shallow, none of the larger vessels can come closer than within two miles of shore, so all of the discharging is done onto lighters from ships.

In order to overcome the danger and difficulty of getting the lighters unloaded, a cableway was built during the winter of 1906-7 and started operation with the first boats of 1907. This has a span of 1400 ft. The shore or head tower is 125 ft. high and the sea tower is 80 ft. high. Both towers are of frame construction, but the sea tower is built on a concrete caisson which is submerged in the water. The caisson was constructed of wooden framework, which was taken out over the then frozen Bering Sea for a distance of about 900 ft., requiring 32 horses to haul it. A hole was cut in the ice and the frame was sunk down into the ice and filled with concrete, and on top of this foundation the tower was built. This caisson is the only thing that has successfully stood up against the violent storms in the Bering Sea during the open season and the action of the frozen sea during the winter months.

In addition to human freight, material of all kinds is handled which includes express, gold bullion, baggage, and the United States mail. During last season nearly 12,000 tons of coal alone was handled. Each season from 30,000 to 50,000 tons of freight is handled and in the neighborhood of 5000 passengers use the cableway for reaching shore. Ordinarily, loads of from three to five tons are handled, but in emergencies as high as 12 tons have been lifted. Freight and passengers are discharged from the ship to lighters two miles from shore, and the lighters are towed under the cableway, which then picks up the loads and takes them ashore. Leschen rope is used on the falls, haul lines, button lines, and slugs and is giving entire satisfaction. Since the construction of this cableway there has practically been no delays in unloading vessels. After the violent storm of October 6, 1913, work of discharging the steamship *Victoria*, which was in the roadstead, was commenced within a few days.

Mediation in Mexico

Mediation in Mexican affairs by the A B C countries of South America is most timely and appropriate. It may not result in settling the points at issue, but that will detract nothing from the courtesy of the attempt, and substantial good will have been accomplished, whether or not the mediation be successful in itself. Despite the insistence of those who have it that order cannot be restored in Mexico except by annexing that country to the United States or establishing a formal protectorate, public sentiment here is adverse to any extension of our boundaries so as to include a Latin American people. This is not generally believed in Central and South America, but it is none the less true. Possibly we deserve no credit for it, since mixed with the idealism that is a real, though often unregarded, factor in American public policy, there are many practical and selfish motives. The sober sense of the American people recognizes that we have not made a conspicuous success in handling the great race problem that we already have, and there is everything to lose and nothing to gain by permitting another such problem to arise. To add to our population 17,000,000 Mexicans would give us a race problem of first magnitude, especially since the addition would necessarily be the result of war and accompanied by much bitterness. Whether the Mexicans be better or worse than the people of the United States does not enter into the problem: there can be no absolute standard for comparison of various races and nations. It is sufficient to know that they are different: different, as Caesar said, in institutions, language, and laws. They do not understand us, and we by no means, as a nation, understand them. We wish them well, but even as neighbors the gulf between their habits of life and thought and ours, has proved to be too deep for any crossing of the people *en masse*. Happily, as always, individual Mexicans are thoroughly liked and appreciated in the United States, and, we believe, individual Americans are equally *persona grata* in Mexico.

A democracy such as the United States, requires for its successful operation a reasonable homogeneity of ideals on the part of those who compose its rank and file. Otherwise the strong few dominate, and it becomes an oligarchy. We have absorbed many alien strains and we shall doubtless continue to do so. Men

of any race or people are welcome so long as they do not come in such numbers as to constitute a threat to our institutions. Many Mexicans live in the United States, especially in the Southwest, and they contribute greatly to its prosperity and are helping to make that part of the country as thoroughly orderly and civilized as any; but it would be a radically different thing to absorb the whole Mexican nation, and none know this better than the people of the United States.

On the other hand, it is equally out of the question for the soldiers of the United States to police permanently an alien country. That is as foreign to our ideals and purposes as to take into our sisterhood of states others dominantly populated by another race. From our own point of view, and disregarding for the moment all questions of right, we are not willing to impose ourselves on an unwilling people. Such sentiment in that direction as was called into being by the Spanish-American war has largely disappeared before the actual difficulties of the situation in Cuba and the Philippines, and in Cuba at least we were not unwelcome. If the American people could be convinced that the Filipinos would maintain a strong, independent, and just government, our forces and officials would be withdrawn instantly. They stay because there is doubt on that point. In nothing does Mr. Wilson better reflect the deep underlying sentiment of the average American home than in his statement that the United States wants no conquests. We do want peace and order. We do want our people, our flag, and our rights as strangers in a foreign country, to be scrupulously respected, and our troops are in Mexico to secure these things. If they go beyond this and 'intervene' it must be to secure for the Mexicans what they themselves want. We cannot stay in Mexico except to execute the Mexicans' will, and, fundamentally and finally, the Mexicans must determine what they will have and then maintain themselves in it. What the Mexicans really want is none too apparent. Seemingly, as in other countries, different Mexicans want different things, and not all can be accommodated. It is by no means certain that either the people or the government of the United States correctly interprets public opinion in Mexico. Such mistakes have been made. It should be remembered that when King Peter came to the throne in Servia he was not recognized by any of the great powers of Europe for more than a year, because of the manner of his accession. Eventually it appeared that he really did represent the hopes and aspirations of Servia. Possibly Huerta represents what Mexicans want, but we doubt it. We must assume that Mr. Wilson has sources of information not open to his vociferous critics of the street corner and country store, and there can be no question of his unselfish and disinterested purpose to live up to the highest ideals of America. If he is in error in thinking it worth while to strive for a larger measure of democracy in Mexico, to set his face against the anachronism of dictators in

Latin America, to hold that it is possible to use even force and retain the friendship of the Mexican people, if, we say, these ideas prove to have been too idealistic for the twentieth century, his effort is none the less honest and commendable. Speaking for ourselves, we do not believe the effort foredoomed to failure, and it is to be remembered that the whole of the President's plan is not yet known. Enough has developed to make it clear that it is his purpose to avoid war by every honorable means, and therefore mediation by Brazil, Argentine, and Chile is welcome. These great countries have passed through many such a crisis as now confronts Mexico. There is a kinship of experience, and with Chile and the Argentine, of race and language, between Mexico and the mediating nations. It is reasonable to assume that if we in our reputed 'duller' Anglo-Saxon manner have misinterpreted conditions, the diplomats of these countries will be able to see the facts and present them to us. It is also possible that the Mexican officials will accept unpleasant truths from those they hold as kinfolk better than from us. In any event, the most hopeful effort at peaceable settlement of the matter will have been made and in event of war the United States will stand in better light before our South American neighbors, a most important matter.

But why war? Mexicans must some day learn to govern themselves. They must give up the easy way of permitting dictators to follow each other in endless succession and impoverish the country. There are able Mexicans and many of them, but they, in the main, stay out of politics. The situation is not greatly different from that in the worst days of boss-ridden American cities. The best men and the average citizen neglected civic duties and a few of the worst ruled. Mexicans are properly unwilling that a foreigner should rule them, but submission to irresponsible local despots is not only as bad in itself, but it may force the very foreign domination that Americans as well as Mexicans are anxious to avoid.

Stripping Frozen Gravel

In gold dredging in the Far North, the cost of stripping is most important. The success or failure of a company may be determined by this important factor. The handling of frozen ground in stripping operations is the subject of a most interesting article by Mr. E. E. McCarthy which appears in *The Mining Magazine* for April. Mr. McCarthy, by reason of long experience in Alaska, is especially fitted to write upon the dredging problems of that country, and he has performed a real service in setting forth in detail the actual experience of the Yukon Gold Company with thawing by stripping. The Canadian Klondyke officials expect to thaw ground at a cost of 10 cents per yard or less. Mr. McCarthy believes them over-optimistic and gives reasons for the doubt that he entertains. The present method of removing the frost from creek gravels, one which has come to be standard practice,

is by the direct introduction of heat by means of steam, except in small workings where the scope of operations will not warrant a steam plant and the ground is thawed by fires. In the *Mining and Scientific Press* of January 17, Mr. Arthur Gibson described this method as used at Nome and analyzed the costs.

At a recent meeting of the Northwest Corporation, Limited, it was reported that 2,000,000 cubic yards of gravel had been stripped, thawed, and made ready for dredging at a cost of 8 cents per cubic yard, and also in the report of the proceedings of the Granville Mining Company, Limited, that the total estimated cost of thawing and dredging the gravels is 10 cents per cubic yard, which is pointed out in marked contrast to the Yukon Gold Company's average cost of over 30 cents for doing a similar work. The proposed method for preparing the ground for dredging is not new, having been tried in both the Klondike and the Forty Mile district, and elsewhere. It consists in removing all trees and brush, and from one to two feet of moss and vegetation which overlies the 'muck'—a mixture of organic material, sand, and silt cemented by ice. For removing this frozen material, the water from the creek is brought to the dredging site by ditches and then allowed to cut through the frozen formation in a series of diagonal or cross ditches and thus sluice away the 'muck.' Sometimes the entire creek is diverted into the frozen ground. The cutting action of the water may be augmented by the use of 'giants', which keep the channels open and wash down the 'muck' as thawed. In this manner the latter is removed to the level of the creek gradient. When the 'muck' overlying the gravel has been removed, the gravel is thawed by exposure to the heat of the sun and in this manner is made ready for dredging.

This apparently simple method of preparing the ground for dredging is not free from difficulties. The moss and vegetation which overlie the 'muck' must be removed, as it will not float, and when it gets into the channels it prevents the water from cutting away the overburden. To get the best results, the course of the creek must be straightened in order to obtain the maximum gradient and most efficient cutting action. The strata of fine sand often found in the 'muck' stop the cutting action of the water in the ditches, and when these strata are thick, plows and scrapers must be used to remove the sand. In no case can the overburden be removed below the creek gradient, and, since as the stripped area increases the grade of the cross-ditches decreases, the carrying power of the water diminishes and more hand labor is required. The supply of water must be abundant.

The experimental work that the Yukon Gold Company conducted on a large scale in 1906-1907 and 1909 was conducted, as pointed out by Mr. McCarthy, under favorable conditions. Nevertheless, difficulties were numerous, and it was demonstrated that stripping and natural thawing could not be relied upon for large-scale operations. The result of this experiment by

the Yukon company, in addition to proving to their satisfaction that the actual stripping operations were fraught with difficulties, showed that the natural thawing of the underlying gravel was by no means satisfactory. Practically all of the ground had to be thawed by steam before the dredge could operate, although the gravel was exposed for almost a season. Gravel which was exposed for more than a season was found to be only about fifty per cent thawed when reached by the dredge. It is not possible to state from the data available what percentage of the thawing was due to stripping operations and how much was naturally thawed before operations began. The belief of the superintendent is that the thawing due to stripping was altogether disproportionate to the expense of the work accomplished. Figures presented by Mr. McCarthy would show that if the Yukon Gold Company had used the natural thawing method in 1913, to strip and prepare the ground for the year's dredging in a season of 120 days, it would require 2360 miner's inches of water daily. With the available supply this work would have required approximately twelve years.

In making a comparison of dredging costs by different companies it is exceedingly difficult, if not impossible, to draw parallels and make deductions as to relative efficiency of methods from the cost per cubic yard of material handled. Local conditions are, of course, the all-powerful factor in working placer properties, and any analogy which does not allow this feature due consideration is ridiculous. One might compare the cost at the Lena Goldfields of about \$8 per cubic yard with that at Natoma of 4½ cents and deduce a relative efficiency of operations which would be absurd. Tabulation of costs of working placer deposits in different parts of the world illustrates the wide range of conditions rather than economy in operation.

Representative recent figures are quoted below:

| | Per cubic yard. |
|---|-----------------|
| Bright district, Victoria, Australia..... | 5.57 cents |
| Dawson district, Klondike | 29.53 cents |
| Iditarod, Alaska | 64.33 cents |
| Natoma, California | 4.50 cents |
| New Zealand dredges | 4 cents and up |
| Oroville, California | 6.78 cents |
| Philippine dredges | 4 cents and up |
| Tin dredges in Siam | 5.4 cents |
| Yuba Consolidated, California | 4.70 cents |
| Lena Goldfields, Siberia | \$6 to \$8 |

There is no standard scale of cost for doing this work. The variation in local conditions is also reflected in the working time. In 1913 the Yukon Gold at Dawson worked 163 days, and at Iditarod 203 days. The Canadian Klondyke company, in the Dawson district, operated 268 days. The difference in working time of the Dawson companies would indicate a marked dissimilarity of local conditions even in the same general district. This spring the Canadian company had been operating for several weeks before the Yukon company began operations.

THE COMMONWEALTH MILL.

Milling Operations at the Commonwealth Property

By E. H. LESLIE

The mine and mill of the Commonwealth Mining & Milling Co. are situated at Pearce, in Cochise county, Arizona, on a branch railroad of the Southern Pacific which extends from Cochise to Gleason, and is connected at Courtland with the El Paso and South-western Railway, which has Douglas as its terminal. The property consists of 10 patented mining claims and two millsites, which with an additional leased mill-site of 20 acres, makes the property comprise a total of approximately 230 acres. The operating company is controlled by the Montana-Tonopah Mining Company.

History of the Property

Ore was discovered here by the Pearce brothers in 1894 and in 1896 when the workings had reached a depth of 50 ft. the property was sold for \$275,000 and ore was shipped to El Paso and Pueblo. At this time a 200-ton pan-amalgamation mill was built, which was destroyed by fire in 1900. An 80-stamp mill was then erected on the site of the old mill which continued in operation until 1904, when in December of that year a cave-in at the mine resulted in the suspension of operations. The tailing was then leased by Messrs. Swatling and Smith, and a year later the mine was also leased by these gentlemen and a period of prosperity was entered upon which resulted in a production of approximately \$10,000,000. In 1909 a renewal of the lease was refused by the owners and Messrs. Swatling and Smith bought a controlling interest in the plant and after considerable experimental work decided to remodel and enlarge the milling equipment. At this time, due to defective wiring, the mill was again destroyed by fire and the new owners, having exhausted their resources in the purchase of the property were not in a position to rebuild and the property later passed into the control of the Montana-Tonopah Mining Co. The condition of the property at this time was reported by Llewellyn Humphreys to the Montana-Tonopah Mining Company.*

The new Company has spared no expense again to

place the property upon a dividend paying basis and toward this end has improved the mining equipment and method, and erected a new mill, after considerable experimental work, for the treatment of the Commonwealth ores. The mill which was placed in commission last year is at present going through the process of being 'tuned up', and complete metallurgical results are not available for publication. It is anticipated, however, that the near future will see those details of the practice, which go to produce the most efficient results, perfected and a most economic treatment established.

Hoisting Equipment

The fairly low-grade oxidized ore, which is being mined by a shrinkage-stope method, is delivered at the surface through a new three-compartment inclined shaft, which is 5 by 17 ft. in dimension, in 3-ton skips manufactured by the Denver Engineering Works Co. The hoist is an Allis-Chalmers slow speed and double drum type gear connected with a 100-hp. motor. The drums are 54 in. diameter and 36 in. wide, using a $1\frac{1}{4}$ -in. rope with a rope speed of 400 ft. per minute. The total unbalanced load is 10,000 lb. The motor is the 3-phase type and operates on a 440 volt, 110 amperes, and 60 cycle circuit at 695 r.p.m. The drums are arranged for balanced or independent hoisting. Double deck cages, as shown in B, Fig. 11, of special design are used for the handling of men, these man-cages being capable of hoisting 18 men at a time. The head-frame is of the 'A' type as shown in A, Fig. 1, and built of structural steel. The frame which was designed for the new 60° incline shaft is 45 ft. high and weighs 37,000 lb. The diameter of the sheaves is 6 ft. The 3-ton skips are 3 ft. by 3 ft. by 7 ft. 5 in. with a 41-in. gage and are fitted with safety catches for 6 by 6 in. guides.

Built in the head frame are two bins for ore and waste which will be seen in the illustration, above which is a 'butterfly' for diverting the material into either of the bins as required. Both bins have inclined bottoms, the waste bin having a capacity of 38 tons and the ore bin a capacity of 21 tons. The waste is discharged through two 24 by 30 in. gates into steel in-

*The Commonwealth Mine, by Llewellyn Humphreys. *Mining and Scientific Press*, June 8, 1912.

dustrial cars and trammed to the dump. The ore is discharged from the bin through two air-actuated ore-bin gates 24 in. wide with a 28-in. lift, into a 2-ton wooden ear, which is saddle shaped and self-dumping. When the car is filled it is removed by a C. W. Hunt automatic railway, shown in C, Fig. 1, which has an outside gage of 21 in. The car passes over a 4-ton weighing scale and is automatically discharged into a circular steel ore-bin of 650 tons capacity. The track over which the automatic tramway operates is 148 ft. long and is supported on a wooden trestle and the ore-bin. The ore-bin is 24 ft. in diameter and 29 ft. high and built of $\frac{1}{4}$ -in. steel plate. This bin serves as a storage and feed bin for the preliminary crushing house, which is at a lower level than the bin and being a hill-side site permits of the gravity handling of the ore.

The ore is drawn from the bin through a 3 by 5-ft. 'finger' gate, which is made of seven wooden fingers with steel lining, and discharged on the feed floor of the No. 6, style 'K', Gates gyratory crusher. One man a shift tends the 'finger' gate and gyratory feed. The crusher discharges into a Gates iron frame revolving screen, which is 40 in. by 12 ft. and makes 18 revolutions per minute. The material passing through the screen, which is through $1\frac{1}{2}$ in., drops into a wooden hopper and thence through a launder chute upon the belt conveyor to the mill bins. The oversize from the screen is discharged into a steel hopper with a deflector arrangement by which the oversize material may be fed into one or both of two No. 4 style 'K' Gates gyratory crushers which reduce the oversize to through $1\frac{1}{2}$ inch. The discharge from the No. 4 crusher is to the same belt conveyor as the undersize from the screen, and the entire product is elevated to the sampling plant and mill bins. The preliminary crushing plant is driven by a 100-hp. motor.

Sampling Plant

A Stevens-Adamson conveyor is used to elevate the ore from the crushing house to the mill. The conveyor is 274 ft. long and 18 in. wide and operates on a 20° incline. Power for the conveyor is supplied by a 15-hp. Allis-Chalmers, 3-phase motor operating on a 440-volt circuit with 19 amperes and making 1150 r.p.m. The discharge is into a hopper at the bottom of which a No. 2 Vezin sampler cuts a $\frac{1}{10}$ sample. The Vezin makes 18 r.p.m. The reject then falls upon another conveyor which delivers it to the bins. This conveyor has a length of 95 ft., is 18 in. wide, and is fitted with an automatic self-propelling and reversing tripper. The speed of the belt over the bins is 300 ft. per minute.

Returning to the sampling plant the cut taken out by the Vezin sampler is discharged into a 30 by 14-in. pair of crushing rolls, making 100 r.p.m., the product of which is through $\frac{3}{8}$ in. The discharge from the rolls passes to a revolving drum mixer, the dimensions of which are 30 by 36 in., and operates at 15 r.p.m. The discharge from the mixer passes to a No. 1 Vezin sampler which makes a $\frac{1}{10}$ cut, two cuts for each revolution, and revolves at a rate of 25 r.p.m. The sample so taken passes to a second set of rolls which are 18 by 10 in. and reduce the sample to $\frac{1}{8}$ in. These rolls operate at 150 r.p.m. From the rolls the crushed product is discharged into a second drum mixer of the same dimensions as that mentioned above, the discharge from which passes to a No. 1 Vezin sampler which cuts $\frac{1}{20}$ th part of the discharge for the sample. This Vezin makes 25 r.p.m. The sample thus taken is discharged on the quartering floor, where it is reground in a small gyratory grinder, the sample quartered and sent to the assay office. The reject from the various Vezin samplers is discharged through chutes

FIG. 1. A, HEAD-FRAME; B, MAN CAGES; C, HUNT AUTOMATIC TRAMWAY.

to the foot of a bucket-belt elevator which raises it 52 ft. and discharges upon the belt conveyor which conducts the ore to the mill storage-bins. The elevator is 8 in. wide, fitted with 72 buckets, and has a belt speed of 1400 ft. per minute.

The battery bin is of the standard type and the dimensions are 16 by 16 by 60 ft., with a storage capacity of 800 tons. The ore is discharged at the bottom through six, 24 in. by 4 ft. 4 in. gates to the stamp batteries. The stamp batteries are fed by six suspended Challenge ore feeders. The ore from the feeders passes over 2 by 3-ft. shaking screens with hoppers for the undersize material which is through 3/16-in. holes. This undersize material is by-passed through an 8-in. pipe through the stamp foundations and joins the battery discharge at the front of the mortar box, solution

FIG. 2.

being added to this undersize material as it drops into the by-pass. The arrangement of the feeder, screen, and by-pass is as shown in Fig. 2.

The oversize is fed with solution into the mortars of three 10-stamp batteries, the weight of the stamps being 1550 lb., each of which drop 7 in. and make 100 drops per minute. The three batteries are driven by individual Allis-Chalmers 40-hp. motors which operate on a 440-volt and 52-ampere circuit, and make 575 r.p.m. The motors are belt connected to a countershaft which in turn is connected by pulleys and belts with the regular idler pulleys to the cam shafts. The countershaft pulleys are 30 by 17 in. and the cam shaft pulleys are 72 by 17 in. Each battery of ten stamps is operated by two separate camshafts with their individual pulley and belt connections with the countershaft drive. The by-passing of the undersized material amounts to about 10% of the total feed, and thereby

effects an increase duty. The batteries were built by the Allis-Chalmers Co. and are most efficient both as to construction and operation.

Battery Foundation

The foundations are adopted from the South African practice, and method of anchoring motor boxes and frames are as shown in Fig. 3. The anchor bolts pass vertically through 2½-in. pipes into the man-way through the centre of the foundation and are thus easily accessible. The mortars of each battery are in this manner rigidly connected with the concrete foundation by 28 anchor bolts. The thickness of the stamp foundation which is between the base of the mortar and the man-way underneath, is 5 ft. For handling the batteries a traveling crane with block and

FIG. 3.

tackle has been placed over the stamps. The battery guides are of the 'Ideal' type, which are proving most satisfactory, and 'fingers' are provided for hanging up individual stamps. Four-mesh screens are employed on two batteries and two-mesh screens on the third battery. It is, however, proposed to change all screens to two-mesh. Battery screen analysis on discharge through the four-mesh screen shows the following results.

| | |
|------------------------------|--------|
| + 20-mesh test screen | 35.5% |
| + 30-mesh test screen | 10.3% |
| + 60-mesh test screen | 9.5% |
| + 100-mesh test screen | 14.0% |
| - 100-mesh test screen | 31.2% |
| | <hr/> |
| | 100.5% |

Screen analysis of discharge through two-mesh battery screen was as follows:

FIG. 5. A. STAMPS AND HARDINGE MILLS; B. HARDINGE MILL DRIVE; C. TUBE-MILLS AND DORR CLASSIFIERS.

| | |
|-----------------------------|--------------|
| + 20-mesh test screen | 43.5% |
| + 30-mesh test screen | 9.5% |
| + 60-mesh test screen | 8.5% |
| +100-mesh test screen | 12.0% |
| —100-mesh test screen | 27.2% |
| | <hr/> 100.7% |

The estimated stamp duty on the four-mesh batteries was 9.3 tons, which will be materially increased when replaced with two-mesh. The discharge, together with the by-passed material from the stamp batteries, is conducted by launders to three 5-ft. Caldecott cones. The underflow from these cones supplies feed to three 8-ft. by 30-in. Hardinge mills, while the overflow is by-passed and joins the discharge from the Hardinge mills and goes thence to three Dorr classifiers. A cross-section of the Caldecott cones as used in this installation is shown in the accompanying diagram, Fig. 4.

Coarse Grinding Equipment

The Hardinge conical mills are driven by individual 50-hp. Allis-Chalmers motors making 680 r.p.m. The mills operate at 28 r.p.m. Nine hundred pounds of

in this mill, a representative screen analysis of the feed and discharge shows the following results:

| | Feed. | Discharge. |
|-----------------|--------------|-------------|
| + 20-mesh | 41.5% | 6.5% |
| + 30-mesh | 11.0% | 5.5% |
| + 60-mesh | 10.5% | 10.0% |
| + 80-mesh | 14.5% | 21.5% |
| +100-mesh | 4.5% | 6.5% |
| +120-mesh | 5.0% | 8.5% |
| +200-mesh | 4.0% | 7.0% |
| —200-mesh | 9.5% | 33.5% |
| | <hr/> 100.5% | <hr/> 99.0% |

The discharge from the Hardinge mills together with the overflow from the Caldecott cones unite and are re-distributed through a system of launders as shown in Fig. 5, C to three duplex Dorr classifiers. These classifiers are driven from a long countershaft, seen in the halftone, by one 5-hp. Allis-Chalmers motor which is operated on a 440-volt circuit at 1150 r.p.m. The three classifiers and three tube-mills, shown in Fig. 5, C, work in closed circuits. The coarse material from the Dorr classifiers is picked up by a scoop feed and discharges into the tube-mill. It is proposed, however, to alter the tube-mill feeding device and to substitute a spiral screw feed for the present arrangement. The work being done by the tube-mills is shown by the following screen analyses of the tube-mill feed and the slime discharge from the Dorr classifiers which goes to the first set of Dorr thickeners.

Tube-Mill Feed

| | Dec. 20. | Jan. 22. |
|-----------------|-------------|--------------|
| + 20-mesh | 11.5% | 9.5% |
| + 30-mesh | 9.0% | 7.0% |
| + 60-mesh | 14.5% | 11.5% |
| + 80-mesh | 33.5% | 23.5% |
| +100-mesh | 8.5% | 12.0% |
| +140-mesh | 7.5% | 14.5% |
| +200-mesh | 4.5% | 9.5% |
| —200-mesh | 10.0% | 13.5% |
| | <hr/> 99.0% | <hr/> 101.0% |

The Dorr classifier slime or the product of the tube-mill shows the following screen analyses:

| | Dec. 20. | Jan. 22. |
|-----------------|--------------|-------------|
| + 60-mesh | 0.5% | |
| + 80-mesh | 9.0% | 0.5% |
| +100-mesh | 5.5% | 2.5% |

From these two analyses it will be seen that the degree of fine grinding is variable but a mean between these two analyses given would be about the normal practice. At the present time the management is contemplating an increase in the tube-milling capacity by the addition of an extra mill which it is believed will materially increase the present capacity of the plant, which is about 280 tons per day, and will also improve the metallurgical results.

FIG. 4.

Danish pebbles are used in the three Hardinge mills per day and an equal amount are used in the tube-mills. The Caldecott cone feed, motor connections, and gear drive, together with the foundations and arrangement of these mills are as shown in Fig. 5, A and B. The Hardinge mill as a coarse grinding machine has proved a most efficient means for the reduction of ore

FIG. 6. A, POWER PLANT; B, OLIVER FILTERS; C, PRECIPITATION PRESSES AND SMELTING FURNACES.

Dorr Thickeners

The fine material separated by the Dorr classifiers goes to the first set of two Dorr thickeners. These vats are made of California redwood and are 38 ft. in diameter and 12 ft. high. The two thickeners are driven by one 3-hp. motor which operates at 1130 r.p.m. Lime is added in the feed launders of the Dorr thickeners at the rate of about 13 lb. per ton of ore. The NaCN consumption is about $\frac{3}{4}$ lb. per ton of ore treated.

The overflow from the Dorr thickeners is conducted to a 20 by 10 ft. mill solution return sump, while the thickened discharge is elevated by two air-lifts which are respectively 6 and 8 ft. to the Pachuca vats. The air-lifts are made of 4-in. pipe with $1\frac{1}{4}$ -in. air inlets. It is proposed to replace these air-lifts by diaphragm pumps, as they are not giving the best results. As an emergency pump a 4-in. direct driven centrifugal slime pump for a 20-ft. head driven by a 10-hp. motor at 680 r.p.m. is used. The thickened products are thus elevated to the first two of a battery of 9 Pachuca vats. Seven of these vats are 38 ft. high and 12 ft. in diameter and two are 36 ft. high and 12 ft. in diameter. Continuous circulation of the pulp is maintained through eight of these vats, the other being kept as a reserve. The air for the vats is furnished by a steam driven Ingersoll-Rand compressor with an 18 by 14-in. air cylinder and 12 and 19 by 14-in. steam cylinders. The compressor has a capacity of 1500 cu. ft. of free air per minute which is compressed to 20 lb. pressure. The exhaust steam from the compressor is circulated through coils in the first four of the series of Pachuca vats, the greater number of coils being in the first two vats. In this manner the temperature of the pulp which is being agitated is raised to approximately 85°F. In passing the pulp from one vat to another the cut is taken close to the discharge of the air lift and the launder connection with the next vat discharges at the top and close to the periphery of the following vat in the series. In the operation of these vats no sleeves are used on the air valves.

The discharge from the last of the battery of Pachuca is conducted to the first of two sets of two Dorr thickeners each. These thickeners are made of California redwood and are 42 ft. in diameter and 12 ft. in height. The rabbles are driven by a 3-hp. Allis-Chalmers motor operating at 1130 r.p.m. on a 440-volt circuit. One revolution of the rabbles is made every eight minutes. The overflow from these first two Dorr thickeners is conducted by launders to a 20 by 12-ft. overflow rich solution sump. The feed to this first set of two Dorr thickeners, which is the slime from the Pachuca vats, enters at about $2\frac{1}{2}$ parts moisture to 1 of solids and the thickened discharge from the same contains $1\frac{1}{2}$ moisture to 1 of solids. This thickened discharge is elevated by two air-lifts, these lifts being 6 and 4 ft. respectively and made of 4-in. pipe with $1\frac{1}{4}$ -in. air inlet. After being elevated it is diluted with barren solution to $2\frac{1}{2}$ parts moisture to 1 of solids,

which in turn is thickened in a second set of two Dorr thickeners.

This second set of thickeners is identical in size and equipment to the first set previously described. The slime is thickened in this second set from $1\frac{1}{4}$ to $1\frac{1}{2}$ of moisture to one of solids and is discharged as such into the filter tanks of four Oliver filters, seen in Fig. 6, B. The overflow from this second set of Dorr thickeners is conducted to a 20 by 12-ft. overflow sump for poor solution. Both this and the rich-solution sump are made of California redwood. The solution from the poor-solution sump is pumped by a 4-in. direct-connected Buffalo centrifugal pump against a 60-ft. head to the mill solution return sump. This pump will handle 300 gal. per minute and is driven by a 15-hp. motor operating at 1150 r.p.m. on a 440-volt circuit. A similar pump is held in reserve for the same purpose. It is believed that with the substitution of diaphragm pumps for the air-lifts for elevating the thickened discharge from the Dorr thickeners, a more satisfactory operation of this department will be obtained.

Filtration Plant

The Oliver filters are built in units of two each. The two filters, comprising one unit, revolve in opposite directions, thus bringing the tailing discharge into one launder, which is between the two filters of each unit, through which it is sluiced to the tailing pond. These filters are 11 ft. 5 in. long by 18 ft. diameter, and make $1\frac{1}{7}$ r.p.m. The power for driving them is furnished by a 15-hp. 3-phase Allis-Chalmers motor making 1150 r.p.m. operating on a 440-volt circuit. The capacity of the individual filters is from 90 to 100 tons each. Moisture in the discharge is about 3%. The filters are of the most modern Oliver type and are fitted with the jet atomizers for washing and have both mechanical and air agitation equipment in the bottom of the V-shaped steel filter-tanks. The vacuum of the filters is furnished by a 20 by 12-in. duplex belt-driven dry vacuum pump making 125 r.p.m. The drive for this pump is a 35-hp. motor making 680 r.p.m. and operated on a 440-volt circuit. As a reserve there has also been installed a 14 by 14-in. belt-driven rotary vacuum pump. This pump makes 300 r.p.m. and by shifting the belting is driven by the same motor as the duplex vacuum pump. The filtered solution is drawn into a 36 by 96-in. receiver, from which it is pumped by a 3-in. direct-driven centrifugal pump to the poor-solution sump. This pump is driven by a 5-hp. motor making 1150 r.p.m. and operating on a 440-volt circuit. An identical pump is held in reserve for the same purpose in case of a breakdown.

The solution from the rich solution sump is pumped by a 4-in. direct-driven Buffalo centrifugal pump to two Merrill clarifying presses. These presses are made up of 36 by 36-in. frames and have a capacity of 750 gal. per day. The clarified solution from these presses flows to a 16 by 10-ft. storage tank and from thence is pumped by a Buffalo single acting triplex pump with $8\frac{1}{2}$ by 8-in. cylinders and making 45 strokes per

FLOW-SHEET OF COMMONWEALTH MILL.

minute. This pump will operate against a 120-ft. head and has a capacity of 300 gal. per minute. The pump is driven by a 15-hp. Allis-Chalmers motor making 860 r.p.m. operating on a 440-volt circuit and 19.5 amperes. An identical pump is held in reserve to be used in case of a breakdown of the one in operation.

Precipitation

Zinc dust is added to the solution at the suction end of the triplex pumps and is fed into the solution by means of an improved Merrill zinc-dust feeder fitted with a screw feed. The zinc-dust feeder is operated by a belt connected with the triplex pump, and the pump is automatically started and stopped by means of a float valve in the rich-solution sump which starts the motor when a specified amount of solution has collected in the sump.

The rich solution is thus pumped to two Merrill precipitation presses which are situated in the smelting house, an interior view of which is shown in Fig. 6, C. These presses are made of 38 by 52-in. frames and have a capacity of 750 gal. of clarified solution per 24 hours. The precipitate collected in these presses is removed twice a month and dried in a 6 by 10-ft. steam dryer which consists of a sheet iron pan with steam coils underneath and a screen top which is attached with padlocks. The precipitate, when dry, is fluxed and smelted in two Donaldson tilting crucible furnaces, No. 275, and the bullion cast in bars for shipment.

Power Plant

The power plant, which supplies power for both mine and mill, consists of a battery of 9 boilers, 5 of which are Woods safety tube boilers, manufactured by Fraser & Chalmers. The engine room, shown in Fig. 6, A, contains a 600-kw. generator which is driven directly by an 800-hp. compound Corliss engine. The mine compressor is compound condensing of the Imperial type, with a capacity of 1700 cu. ft. of free air per minute at sea-level.

The crusher house, mill building, store rooms, power plant, melting house, machine shop, and hoist house are all frame structures with concrete foundations and galvanized corrugated iron sidings and roof. Every effort has been made in the construction of the entire plant to minimize the fire risk and so avoid any possible repetition of the two previous disasters. The hillside millsite has permitted of the utilization of gravity to a large extent in the handling of mill products, while an incline railway is maintained for the handling of mill supplies. The cost of mill construction, as itemized in a recent company report, shows the total amount to have been \$335,271.

From a mechanical standpoint the conduct of milling operations is as near automatic as modern practice has developed and local conditions permit. From a metallurgical standpoint, with increased grinding capacity and a final adjustment of the details of operation, a greater tonnage and increased efficiency is anticipated.

The accompanying flow-sheet presents graphically an outline of the treatment, the equipment, and general arrangement of the mill.

54. Battery tanks with conical bottoms.
55. Steam driven Ingersoll-Rand Compressor.
56. Water tanks.

A 95-ton steam-shovel which has been used at Panama is to be dismantled and shipped to the Brooklyn navy yard, where it will be re-erected and advertised for sale in the United States. Almost all the smaller steam-shovels retired from the canal work have already been disposed of by the Commission on the Isthmus; but it is anticipated that the larger size shovels can be sold to better advantage in the United States.

The top-slicing system has been adopted throughout for mining the Daly vein shoots, in the Daly-Judge mine, Utah, in all of which the ground is exceedingly heavy, often carrying water. All drifts and raises are run in the footwall. The method has given complete satisfaction; the mining has been clean and no ore is lost.

The Portland Canal Tunnel

By LLOYD C. WHITE

The driving of the Portland Canal tunnel was not an important operation either as to costs established or rate of progress; but, on account of its being the largest undertaking of its kind in the district, the methods and costs may be of interest. The work was carried on by the Portland Canal Tunnels, Ltd., a company with head offices at Victoria, British Columbia. The power-plant of the Portland Canal Mining Co. was leased for the work, and this expense is not included in the following costs. Also the underground equipment is entirely written off.

Purpose of the Tunnel

The portal of the tunnel is situated about $3\frac{1}{2}$ miles north of Stewart, British Columbia, and is 300 ft. above sea-level. The objects of the tunnel are to provide a working entry to the mines located in the Portland Canal fissure zone, and to provide a means of further exploring veins in this zone; also to develop water power.

The heading, $7\frac{1}{2}$ by 8 ft. in the clear, was driven a distance of 2916 ft. at an average rate of 8 ft. per day. The best weekly record was 67 ft., and the best monthly 271 ft. Two 8-hr. shifts per day were employed, consisting of four machine-men and three shovelers. After the 1000-ft. mark was passed, four shovelers were employed. Compressed air at 100 lb. pressure was supplied by a water-driven, 520-cu. ft., Rand class D-2 compressor, and delivered into the tunnel through a 4-in. pipe. Two $3\frac{1}{4}$ -in. Ingersoll-Rand E-44 drills, mounted on a 7-ft. single screw bar were used. Miners and shovelers started work together. The bar was set up above the rock pile, and from 10 to 12 holes were drilled from this position. By this time the rock was out, the bar was lowered, and three lifters were drilled. The first 1600 ft. of the tunnel is in greenstones, while the remainder is in argillites, quartz, and porphyry. With but two exceptions during the entire work, a round was drilled every shift. Five-foot rounds were drilled, but seldom 'bottomed.'

Three 20-cu. ft. cars were used, and tramming was done by the shovelers. The track, of 20-lb. rails, 18-in. gage, and $1\frac{1}{2}\%$ grade, was laid on the left-hand side of the tunnel. One switch, about half way in, was used; the empty incoming car was taken off the track near the face to allow the loaded one to pass. At a point 730 ft. from the portal an 80-ft. adit was run, opening into a cañon. This not only made an excellent dumping place, but shortened the tramming distance by 750 ft. The shovelers laid and leveled the track. The floor from within 3 ft. of the face to 40 ft. back was covered with steel plates before blasting. A drain 12 in. deep was made on the right side of the tunnel, the lifter being drilled low for this purpose.

Ventilation was provided by two Schutte & Koerting blowers. The ventilating line consisted of 10-in. diameter, 24-gage, galvanized pipe. The pipe was made in 10-ft. lengths, with riveted joints, painted with tar, and wrapped with muslin. The compressor was run two hours after blasting to clear the tunnel. After the 2000-ft. mark was reached, more or less trouble was experienced with the ventilation, especially in rainy weather. Except in a few places the tunnel was dry, and after the first 140 ft. required no timbering. The writer, who had charge of the work, was the only boss. The tunnel is still being driven, but only as a 5-ft. drift and secondary to exploration on veins found in the tunnel.

Time and Cost of Operations

AVERAGE TIME OF OPERATIONS

| | Hr. | Min. |
|-----------------------------------|-----|------|
| Picking down -Setting up | 1 | 00 |
| Drilling from upper set-up | 4 | 30 |
| Shoveling back—Lowering bar | 0 | 30 |
| Drilling from lower set-up | 1 | 15 |
| Tearing down | 0 | 10 |
| Blowing out holes | 0 | 5 |
| Loading | 0 | 15 |
| Total | 7 | 45 |

DETAILED SUMMARY OF COSTS

| | Total cost. | Cost per foot. |
|--------------------------------|-------------|----------------|
| Labor: | | |
| Machine men | \$11,526.00 | \$3.953 |
| Shovelers | 10,711.00 | 3.673 |
| Timbering | 753.17 | 0.258 |
| Drainage | 123.00 | 0.042 |
| Ventilation | 224.50 | 0.077 |
| Ties and wedges | 394.60 | 0.135 |
| Compressed-air line | 210.00 | 0.072 |

| Powder | \$ 7,469.25 | \$2.562 |
| Fuse | 391.50 | 0.134 |
| Caps | 92.00 | 0.032 |
| Candles | 421.90 | 0.145 |
| Blacksmith coal | 364.50 | 0.125 |
| Machine drills and parts | 1,464.77 | 0.503 |
| Drill steel | 343.57 | 0.118 |
| Timbers | 150.00 | 0.052 |
| Repairs on compressor | 77.40 | 0.027 |
| Oils | 97.00 | 0.031 |
| Miscellaneous | 216.00 | 0.073 |
| Total | \$11,087.89 | \$3.802 |
| Equipment | | |
| Muck sheets | \$ 110.00 | |
| Steel rails | 1,290.00 | |
| Ventilators | 225.00 | |
| Ventilating pipe | 960.00 | |

| | | |
|---------------------------|-------------|-------------|
| Compressed-air line | 1,070.00 | |
| Cars | 400.00 | |
| | | <hr/> |
| Total | \$ 4,055.00 | \$1,391 |
| Length of tunnel | | 2916 ft. |
| Total cost | | \$48,584.01 |
| Cost per foot | | \$16.661 |

All supplies were bought at Vancouver, British Columbia, and came north by steamship. The prices of some of the more important supplies at the tunnel were as follows: 40% dynamite, \$0.134 per pound; 60% dynamite, \$0.159 per pound (powder was used in about the proportion of 30% of the former to 70% of the latter); 20-lb. steel rails, \$72.24 per long ton; blacksmith coal, \$27 per ton. The scale of wages is as follows: machine men, \$4; shovelers, \$4; blacksmith, \$5; compressor men, \$5.

Lead Smelters and Refineries in the United States

By C. E. SIEBENTHAL

The following list of lead smelters and refineries was compiled in connection with the statistical work of the U. S. Geological Survey.

Arizona:

Mowry—Consolidated Mines, Smelter & Transportation Co.¹

California:

Keeler—Four Metals Mining & Smelting Co.

Needles—Needles Mining & Smelting Co.²

Selby—Selby Smelting & Lead Co.³ Refinery also.

Colorado:

Denver—Globe plant, American Smelting & Refining Co.

Durango—Durango plant, American Smelting & Refining Co.

Leadville—Arkansas Valley plant, American Smelting & Refining Co.

Pueblo—Pueblo plant, American Smelting & Refining Co.

Salida—The Ohio & Colorado Smelting & Refining Co.

Idaho:

Clayton—Red Bird Smelting Co.

Enaville—North Fork Smelting & Mining Co.

Ponderay—Idaho Smelting & Refining Co.

Sea Foam—Greyhound Mining & Milling Co.

Wardner—Bunker Hill & Sullivan Co. (Malm dry chlorination process.) Under construction.

Illinois:

Aurora—Aurora Metal Co.⁴

Chicago—Goldsmith Bros.' Smelting & Refining Co.⁴

Chicago—Great Western Smelting & Refining Co.⁴

Chicago—National plant, American Smelting & Refining Co. Refinery only.

Collinsville—St. Louis Smelting & Refining Co.⁵ Refinery also.

Federal—Federal Lead Co.³

Granite City—Hoyt Metal Co.⁴

Indiana:

East Chicago—International Lead Refining Co.⁶ Refinery only.

East Chicago—United States Reduction Co.⁴

¹Not operated for several years.

²Subsidiary of United States Smelting, Refining & Mining Co.

³Subsidiary of American Smelters Securities Co.

⁴Smelters of secondary materials, but treating some lead ore.

⁵Subsidiary of National Lead Co.

⁶Subsidiary of International Smelting & Refining Co.

⁷Subsidiary of American Smelting & Refining Co.

Grasselli—United States Metals Refining Co.² Refinery only. Betts electrolytic process.

Iowa:

Dubuque—J. W. Watters.¹

Kansas:

Galena—Galena Smelting & Manufacturing Co.

Missouri:

Desloge—Desloge Consolidated Lead Co.

Granby—Granby Mining & Smelting Co.

Herculaneum—St. Joseph Lead Co.

Joplin—Picher Lead Co.

Valle Mines—Valle Mining Co.¹

Webb City—Webb City Smelting & Manufacturing Co.

Montana:

Cooke—New World Smelter & Mining Co.

East Helena—East Helena plant, American Smelting & Refining Co.

Nebraska:

Omaha—Omaha & Grant Smelting Co.¹ Refinery only. Betts electrolytic process.

Nevada:

Nelson—Santa Barbara Searchlight Mining Co.

Spruce—Black Forest Mines & Smelting Co.

New Jersey:

Newark—Balbach Smelting & Refining Co. Refinery also.

Perth Amboy—Perth Amboy plant, American Smelting & Refining Co. Refinery also.

New Mexico:

Deming—National Mining & Smelting Co.¹

Pennsylvania:

Carnegie—Pennsylvania Smelting Co.

Texas:

El Paso—Kansas City Consolidated Smelting & Refining Co.¹

Utah:

Midvale—United States Smelting Co.²

Murray—Murray plant, American Smelting & Refining Co.

Silver City—Tintic Smelting Co.

Tooele—International Smelting & Refining Co.

Washington:

Keller—Keller & Indiana Consolidated Smelting Co.¹

Tacoma—Tacoma Smelting Co.³

Wisconsin:

Dodgeville—Blue Mounds Mining & Smelting Co.¹

Waukesha—Northern Smelting Co.¹

LEAD SMELTERS AND REFINERIES IN CANADA

British Columbia:

Trail—Consolidated Mining & Smelting Co. of Canada (Ltd.). Refining also. Betts electrolytic process.

Ontario:

Kingston—North American Smelting Co. (Ltd.).

Of these the following were not operated in the years 1911 to 1913, inclusive: Con. M. S. & T. Co., Four Metals, North Fork, Idaho S. & R. Co., Greyhound, Walters, Valle, New World, Santa Barbara Searchlight, Black Forest, National, Tintic, Keller & Indiana, Blue Mounds, and Northern Smelting Company.

To obtain an estimate of the value of cyanide bullion at the Lake View mill, Kalgoorlie, the specific gravity of the bars is determined by the following means: a vessel 6 in. square by 10 in. deep, with an overflow spout at the top, is filled with water till it is just overflowing. The bar is then placed carefully in the vessel and the water displaced is collected in another tin and weighed. From the calculated specific gravity, and knowing the approximate composition of the base metal present, the value of the bullion may be determined very closely.

Gold Dredging at Surinam, Dutch Guiana

By J. B. PERCIVAL

The gold gravel deposits in Surinam present many obstacles to the usual methods of mining by means of dredges or hydraulic apparatus. In general, the bucket dredge has given the best results, although lack of capital and the problem of handling the clay caused the temporary failure of three dredges which were in operation on Sara creek, the Saramacca river, and the Gross Concession. A fourth dredge arrived a few months ago, and is now being operated on the placer owned by the Guiana Gold Mining Company.

The boat on the Gross concession was in operation for several months, and produced in January and February 1910, 40 oz. of gold. It has buckets of 2 cu. ft. capacity. Sub-lessees are now at work washing the dredge tailing with 'long-toms' to make estimates of the gold recovery of the dredge. This boat is now situated in the richest part of the gravel deposit in the valley, but the gravel which will be dug later does not contain so much gold. Should this dredge prove to be successful it will afford much useful information to other dredging companies, both with respect to the methods of operation, costs, and recovery.

The dredge of the Guiana Gold Mining Co. was erected near the Colonial Railway to dredge a gravel deposit which lies between the railway and the settlement of the Guiana placer. The ground was prospected, and a map made of about 50 acres of the gold-bearing gravel area. The dredge is now close to the railway in a part of the gravel deposit that prospecting has shown to be the poorest of all the area examined. If satisfactory results cannot be obtained in this place, it will be an easy matter to transport the dredge to another part of the valley. Near the settlement the creek valley becomes narrower, the width being about 70 metres, and here the working places of the sub-lessees began. From this point upward the richness of the creek gravels seems to be assured. There is a quantity of gravel along the creek bed, not less than four kilometres in length and about 50 metres in width, which contains at least 0.1 oz. of gold per cubic metre. The height of the gravel banks is estimated to be one metre. These gold gravel deposits continue westward along the railway, but they have not yet been prospected on account of the lack of a cheap and efficient method of drilling applicable to Surinam conditions. The usual method of digging pits is not applicable here, for the ground is too sticky. The presence of large quantities of clay is a serious obstacle for prospecting and dredging in this and other districts.

In dredging it has been found that no type of bucket exists that is able to dig some varieties of the clay overburden of the Surinam gravel deposits. It is said that in Siam clay has been a serious obstacle in digging operations, but the trench experts overcame this diffi-

culty by lining the buckets with wood. This method did not prove to be very successful when applied to the removal of the clay overburden on the Guiana placer. It was then suggested that automatically discharging buckets should be used and this proved to be a simple and satisfactory remedy. The clay overburden is removed and discharged behind the dredge before the gravel is attacked. The solution of the clay problem greatly helped matters, although it took some time before a practical construction was obtained. It is not expected that the clay will be so tough everywhere, but at any rate it is now known that almost any kind of clay can be dug. In this respect the Surinam dredging industry has overcome a great difficulty, and the way seems open to profitable operations.

The problem of handling the gravel on the dredge was worked out after numerous experiments. At present a gravel-disintegrator (log-washer) and common sluices are in use. The disintegrator consists of a wooden sluice in which the gravel is broken up by means of a revolving axle with fins. In addition a small crusher was used for handling the cemented gravel. Trommels are not satisfactory because the boulders and masses of clay slip through the trommel without being washed or crushed. An experiment of this kind on another dredge proved to be an utter failure. With the machinery and methods in use at present on the Guiana placer a recovery of 1.5 grams of gold per cubic metre is obtained from gravel which in place carried 2.5 grams, according to the prospecting tests.

Dredge Requirements

From the experience obtained by dredging operations in Surinam, it has been found that it is necessary for dredges to be designed to suit the peculiar conditions. The boats must be provided with large buckets in order to remove the overburden at small expense. The overburden should not be raised very high. A low hanging ladder and tumbler is used, and the clay is transferred by a belt conveyor to a distance of 15 or 20 yards from the dredge. The material to be removed by the stacker consists of two-thirds clay and one-third gravel. Relatively small quantities of gravel are handled because the dredging must be done with so much care that the buckets are seldom filled to their capacity. As the upper tumbler is low, the gravel is discharged into a hopper, whence it is carried up to the necessary height by a bucket-elevator. The gravel is thus dug up and dumped twice before the extraction of the gold begins, thus facilitating the disintegration. A crusher must be used for the cemented gravel. To disintegrate the gravel a log-washer is necessary, under which may be placed a trommel. The lumps of clay ejected by the log-washer roll through the trommel and over the tables. The bed-rock clay must be caught and subjected to a special treatment for which purpose a small washing machine may be constructed. The success of the dredging operations will largely depend upon the extraction of gold from this bedrock clay.

Bauxite Deposits of France

By AN OCCASIONAL CONTRIBUTOR

Several important companies in France are engaged in the production of aluminum in large plants in Savoy, and another plant is being built for the same purpose. The mineral bauxite (which owes its name to Baux, where it was discovered by the chemist Berthier in 1822) is found in many parts of the world. There are deposits in Hesse and Nassau, Germany; at Neustadt, in Austria, where it was exploited for some years; and the mineral has likewise been found at Carniole and in Styria, at Prichora in particular. A quantity of Dalmation bauxite is exported to Germany from the port of Almissa. The mineral has also been found at Strain, in County Antrim, Ireland, and the British Aluminum Co. works the deposits at Glenravel. Deposits have been found in Australia, New South Wales, and in the United States, where they are being actively worked, as in Alabama, Arkansas, Georgia, and North Carolina.

All the deposits outside of France, says a French authority, are of inferior quality to those of France. French deposits are found chiefly in the Department of Languedoc-Provence (Herault, Bonches-du-Rhone, Var), where they form a band almost parallel to the shore of the Mediterranean. Bauxite has been found also in the Eastern Pyrenees, in the Ariege and in Auvergne.

Bauxite, which is hydrated aluminum oxide mixed with certain impurities such as silica, iron oxide, titanic acid, and carbonate of lime, occurs in numerous varieties even within limited areas. The two principal varieties are red bauxite and white bauxite. The red or ferruginous is compact, pisolitic, and granular. Because of its low content in silicon it is the variety chiefly used for making aluminum. The white bauxite is very silicious, is found in compact masses, and breaks easily. It is chiefly used for making alum and firebricks, for it is infusible at very high temperatures.

The aluminum content of red bauxite sufficiently pure for industrial purposes varies between 57 and 60%, with 2 to 4% of silicon. That of the white bauxites varies between 58 and 70% aluminum, 2 to 3% of iron, and 12 to 15% of silicon. Of red bauxites an excess of silicon over 3% reduces its value by about 2 francs (38c.) per ton per unit.

Bauxite in Provence and the Languedoc

In Provence and in the Languedoc the bauxite deposits are worked in open quarries and sometimes by underground mining, but it is rare that the depth is more than 50 metres from the surface. The exploitation of the Languedoc deposits was begun in 1873, but does not appear to have been carried on at first with great success. However, later, Mr. Auge discovered in the Saint-Porgoire at Villeveyrac (Herault) a heavy bed of white production of bauxite and shortly after the Auge Company was formed for the produc-

tion of firebricks and alum. Afterward the increase in silicon content forced the Auge Company to look for fresh deposits, and thus the fine bed of the Var was discovered, where the silicon does not often exceed 3% of the total. The rapid growth of the aluminum industry is causing increased production of bauxite.

Not much need be said of the bauxite deposit in the Eastern Pyrenees. This discovery was made in the year 1906 by an engineer named Helson. He found the mineral in the Saint Antoine de Calamus chain of hills which extends parallel to the Rivesaltes-Quillain line, several kilometres distance from it. The deposits are found in the Queribus and the Calamus gorges on the southern slope of the chain. It would appear that erosion has removed the bauxite from the northern slope. These deposits are unfortunately found to be too rich in silicon to be of great industrial use. It is believed, however, that they might be utilized for the production of firebricks and perhaps also for alum, but they are not over promising at present.

The following table of analysis of French bauxites has been prepared by Francis Laur:

| | Water content, % | Silica, % | Titanic acid, % | Iron oxide, % | Lime, % | Aluminum, % |
|------------------|------------------|-----------|-----------------|---------------|---------|-------------|
| VAR | | | | | | |
| Red | 12.90 | 1.75 | 21.38 | 3.21 | ... | 60.70 |
| Rose | 14.70 | 19.13 | 5.11 | 3.52 | 0.52 | 56.96 |
| Lilac | 15.09 | 8.11 | 3.07 | 2.85 | ... | 70.80 |
| White | 16.10 | 21.06 | 3.47 | 0.95 | 1.80 | 53.59 |
| BOUCHES-DU-RHONE | | | | | | |
| White | 19.80 | 12.30 | 3.45 | 3.70 | ... | 60.20 |
| Red | 19.80 | 2.20 | 14.00 | 2.50 | ... | 61.30 |
| HERAULT | | | | | | |
| White | 15.10 | 1.60 | 0.67 | 3.80 | ... | 78.53 |
| Red | 12.50 | 5.25 | 24.21 | 2.28 | ... | 55.51 |
| Rose | 15.60 | 5.95 | 5.09 | 2.39 | ... | 70.82 |
| ARIEGE | | | | | | |
| Rose | 14.79 | 12.02 | 4.71 | 3.32 | traces | 64.80 |

These figures are generally correct for average material. The iron oxide may sometimes make up 60% of the bauxite against only 1/2% at times, and the silicon also varies in similar degree. The one or the other may disappear altogether, but they are never both absent from the ore. There is a remarkable similarity between the bauxite deposits of the Var, and certain deposits of the region of Loupian (Herault) remarkably resemble deposits that have been observed in Algeria, at Rouma, and near Oran. It is therefore presumed that bauxite may have a similar origin to iron. Stanislas Meunier believes that bauxite is due to the action of chlorides resulting from the decomposition by heated sea water of the ferruginous clays, but this hypothesis would not apply to the laterites. Like iron, bauxite occurs at various geological horizons.

Washing Gravel at the Mineral Slide Mine

The accompanying illustration shows the method of arrangement of the feed hopper and sluice-box for washing gravel at the Mineral Slide mine near Magalia, Butte county, California. The property is a drift-gravel mine and the material as delivered at the surface through the adit is dumped in the wooden hopper shown in the half-tone, through which it is fed into the

HOPPER AND SLUICE-BOXES.

sluice, where the gold is collected in the riffles in the usual manner. At the present, the operators are washing the gravel down underground with water under pressure and subsequently running it through the sluice-boxes. The method of mining and treatment of the gravel is an experiment at this property, but appears to be promising as a cheap and efficient method for handling the material.

Shipbuilding in the principal countries of the world in 1913 was as follows:

| Country. | Vessel. | Tonnage. |
|----------------------------------|---------|-----------|
| United Kingdom and colonies..... | 737 | 2,203,529 |
| Germany | 201 | 618,783 |
| United States | 222 | 288,042 |
| Holland | 104 | 107,371 |
| France | 102 | 251,986 |
| Italy | 63 | 104,166 |
| Denmark | 35 | 41,682 |
| Russia | 17 | 30,684 |

With the exception of the United States, which showed a decrease of 60,000 tons, all showed an increase over 1912.

Gold output of Charters Towers, Queensland, in 1913 was \$1,470,000 from 78,911 tons of ore.

Tin From Scrap Tin-Plate

Tin is recovered from scrap tin-plate by three methods in Germany, namely, mechanical, chemical, and electrolytic.

In chemical separation, the tin-plate waste is treated at a low temperature with diluted hydrochloric-acid, nitric acid, or sulphuric acid solutions and the dissolved tin drops out with the zinc. Other dissolving agencies have been experimented on with varying success. Much more important than either the mechanical or the chemical process is the electrolytic method of detinning. As a rule, hot caustic soda (liquid) is employed as electrolyte (6 to 7% Na_2O). Loosened chips of tin plate packed in wire baskets act as anodes, while the iron bath walls or iron plates suspended therein serve as cathodes. The average tension is said to be 1.5 volts. When separated, the tin is 'spongiform.'

In other processes acid electrolytes are employed. Thus in the older Siemens & Halske process, chips of tin plate, packed in wood-latticed baskets, serve as anodes, the cathodes consisting of tinned copper. The electrolyte is made up of a solution of 1 part of 60% sulphuric acid and 9 parts of water. The density of the current is about 100 amp. per square meter (10.764 sq. ft.) Recently, Siemens & Halske have also been employing an alkaline electrolyte that offers great advantages over the acid electrolytes formerly used. At any rate, it may be safely stated that the electrolytic methods utilizing acid and ferrosulphate electrolytes have not been shown to possess any practical value.

By far the greatest amount of tin-plate waste is now being detinned by the chloride method that Lambotte, of Brussels, was the first to apply on a large scale. (Imperial German letters patent No. 32517.) The principal requirements for a successful application of this method are absolute exclusion of moisture during the process of detinning, avoidance of an unduly high temperature, and proper washing of the detinned waste. The process is protected by Imperial German letters patent No. 176457, 176456, and 188018. Tin plate contains about 2.5% metallic tin. -*Daily Consular Report.*

Dredging at Iditarod, Alaska

The Yukon Gold Co. has a dredge working at this place, and in 203 days of 1913 handled 496,756 cu. yd. of gravel yielding \$1.67, at a cost of 64.33c. per cubic yard. From the beginning of operations this dredge worked under difficulties. The principal causes of the low yardage and high cost may be summarized as follows: steep grade, $6\frac{1}{2}$ to 10%; large boulders; heavy granitic sand from workings above; scarcity of water for flotation, due to the unusually dry season; and the presence of strata of 'gumbo' clay. The grade and sand were the greatest obstacles. A series of dams had to be built, both before and behind the dredge, which greatly increased the expense. The dredge is now down to where the grade is less and the operation more nearly normal.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

The Rand Banket

The Editor:

Sir—I observe that a misprint appeared in my communication in the April 11 number of the *Mining and Scientific Press*. Equation (3) should read:

$$v/v' = g'm/m'g.$$

J. S. HOOK.

Ithaca, New York, April 15.

Prospecting and Government Aid

The Editor:

Sir—There is so much sound sense mingled with genial constructive criticism in the letter from F. Sommer Schmidt, published under the above heading in your issue of April 4, 1914, as to deserve thoughtful consideration.

With his plea for more scouting work by the government geologists and for the maintenance of closer touch between them and current conditions in those mining districts on which reports have already been published, I am in hearty sympathy; although he perhaps does not fully appreciate the variety and broad value of certain of the other kinds of work in which the United States Geological Survey is engaged, and is apparently not aware that some progress has already been made along lines which he advocates. For example, during the past year or two a special effort has been made to cover in a reconnaissance way, and to issue brief reports on, those metal mining districts in the western states for which no geologic information was available. It is intended not only to present this information promptly, in brief reports, but to utilize it in general summary volumes on the geology and ore deposits of each state. Such a summary has been published for New Mexico, and others for Utah, Idaho, and Arizona are in various stages of preparation. The new district of Rochester, in Nevada, was visited by a geologist within a few weeks of its discovery and a brief account of the geology and of the character of the deposits was furnished to the press before the geologist returned from the field. His full report is now ready for publication.

Requests for geologic information from groups of prospectors working in undeveloped districts are receiving special consideration, and whenever possible a geologist is sent to examine and report on their district. Such a request was received from Arizona only a few weeks ago, and a geologist is already on the ground.

Old districts are being re-studied in the light of later

developments, these investigations ranging from such a complete re-study as was made of Cripple Creek some years ago, or of Leadville (now nearly ready for publication), to brief notes on new developments, such as are embodied in the Bisbee folio, now being reprinted. Some of the results of a careful re-study of the Tintic district have already been published and the complete report will soon be ready for the printer. Provisional plans for the coming field season include a detailed re-examination of the Mother Lode region, California, with special attention to the problems now confronting the miners along that belt; a visit by a geologist to Eureka and to some other old districts, together with considerable scouting among comparatively undeveloped districts.

The great difficulty, of course, which confronts the Survey in attempting to do all that is expected of it, is want of sufficient funds. The geology of metalliferous districts embraces only a part of the varied activities of the organization, and the territory to be covered is so vast that it is impossible with the present appropriations and staff for the Geological Survey to keep in close touch with all that is being done in the mining districts of the West.

In conclusion, let me heartily subscribe to Mr. Schmidt's belief that the Survey will work in closer and closer touch with the mining men as time goes on. The members of that organization would soon cease to be useful if they lost their capacity for learning any lesson that may make for increased efficiency in the service of the people. Neither they nor mining engineers should forget, however, that one great factor in such usefulness is the opportunity to carry out thorough and comprehensive scientific investigations. When that opportunity is denied and the spirit of scientific research quenched, then the type of men who can be retained in the government service will no longer be such as the Geological Survey has hitherto been able to command. The sound practical application of geology to mining must rest upon a solid substratum of scientific research, and demands such training as rigorous scientific investigation can alone supply.

F. L. RANSOME.

Washington, D. C., April 13.

[We are glad to present this letter regarding the purposes and work of the Survey in the West, from the geologist who is in direct charge of the section of metalliferous deposits.—EDITOR.]

Decline of the Rand

The Editor:

Sir—H. S. Denny's article, 'The Decline of the Rand,' which appeared in your issue of January 3, contains the following: "The Rand, since the introduction of the cyanide process in the early days, has done practically nothing to add to the glory of engineering achievements. It has rather followed a policy of sticking to the one old principle and developing the details

of that principle to the last limit. In my opinion, and I share this with a great many other engineers, the Rand might have saved itself a large amount of capital outlay if it had adopted, immediately after the war, for the treatment of its unusually simple clean ores, what has been accepted all the world over in the past ten years, namely, the one-product one-treatment method."

Mr. Denny's opinions may be shared, as he asserts, "by a great many other engineers," but I venture to say, on equally good authority, that there are many engineers and metallurgists of good repute who do not share them. Mr. Denny's is not a novel or an especially disturbing point of view. He is simply reiterating a somewhat time-worn sentiment—I use the word advisedly—which so long as the Rand continues to exist as a mining field, will make its perennial appeal to metallurgical faddists and extremists the world over, and encourage machinery men and inventors to hope for better times. Popular fallacies die hard; but none seems to exhibit a more enduring vitality than the belief that there is something radically wrong with Rand metallurgical practice. One might suppose, after reading this oracular utterance from overseas, that the metallurgists and engineers of the Rand had resolved themselves into a kind of close corporation for the exclusive purpose of nursing and perpetuating obsolete ideas, and jealously opposing the intrusion of up-to-date principles and methods. Even if this were true, it is difficult to see how Mr. Denny's remedy would have helped the industry. In his opinion, all would have been well if the Rand "had adopted, immediately after the war, for the treatment of its unusually simple clean ores, what has been accepted all the world over in the past ten years, namely, the one-product, one-treatment method." This method (by which I understand the writer to mean the reduction of ore to one product and its treatment as such) has not been adopted on the Rand for the simple reason that nothing would be gained by using it. As a pioneer in the introduction of 'all-sliming' in Nevada in 1905, and a strong advocate of its adoption in certain isolated cases where it was applicable, I came to the Rand greatly impressed by its advantages. But I was soon to be impressed in a different way: I was astonished at the effectiveness and low cost of methods which I had come to look upon as old-fashioned or obsolescent. The huge slime and sand plants spread over acres of ground, certainly did lack the neat and desirable compactness of the modern all-sliming plant. Here, at first glance, appeared a most alluring field for the ambitious innovator. It seemed a tempting opportunity to introduce the latest and newest thing with which one was familiar: in other words, to revolutionize Rand practice and become famous! But I must confess that my ardor soon evaporated in the light of incontestable facts. I could not see that anything was to be gained by 'all-sliming,' or by any other radical sweeping change in local practice. Indeed, the arguments against all-

sliming on this field at the present time are irrefutable. The total extraction being what it is—ranging from 94% in the older plants to 97% in the newer—could only be very slightly increased by fine grinding or sliming the sand, since the coarse sand is the poorest product in the plate residue, and the cost of regrinding this material, as experiments have conclusively shown, would leave an exceedingly problematical net gain. Mr. Denny's allusion to capital expenditure does not apply to the plants of more recent construction, where the amortization of initial cost is by no means the serious item he imagines. And even supposing it were, the "one-product, one-treatment method" would hardly appeal to the practical man as an effective remedy. An all-sliming plant on this field, with the huge tube-mill and filtering additions required, would be an extremely expensive installation. Without recourse to a comparative estimate, it is obviously impossible that the mere elimination of sand plant should offset the cost of the additional fine-grinding and filtering equipment required.

The survival of the old system of separate sand and slime treatment on the Rand is easily explained: it has persisted because it is so admirably adapted to the unique local conditions. At all events, nothing better has been found to take its place. Yet in spite of this safe conservatism, which critics often mistake for stagnation, the metallurgy of the Rand has in recent years made solid and distinct progress. The introduction of tube-mills, heavy stamps, vacuum-filtration, and air-lift agitation, are notable among a host of lesser innovations; but it is significant that every deliberate attempt to effect radical changes in our metallurgical system has met with disastrous failure. This is not due, as is popularly supposed, to any niggardly or obstructive policy on the part of the mining houses. Vast sums have been willingly spent on fanciful installations and processes which have lamentably failed, and it is only fair to those companies who have suffered through their amiable credulity, to state their attitude, in the face of overwhelming losses, has usually been most patient and generous. I venture to say that at the present time there is no mining field in the world where more enthusiastic interest is evinced in innovations of real value. But the Rand mining companies, after many costly experiences, have become wary; like the Missourian, they must be 'shown.'

F. L. BOSQUI.

Johannesburg, March 17.

The Strassburg hospital and university some time ago bought 200 milligrams of radium at \$76 per milligram, and has bought 100 milligrams more, which will cost at present prices \$98 per milligram, or at the rate of \$3,000,000 per ounce troy.

Gold received for coinage at the Australian mints during 1913 was as follows: Melbourne, 555,321; Perth, 1,490,933; and Sydney, 540,283 fine ounces.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Opal mined in New South Wales in 1913 was worth £29,493.

Steam-shovel work at the Nevada Consolidated Copper mines cost 17.75c. per ton in 1913.

Mining costs in the Flat River lead district, Missouri, average 85c. per ton.

Ore mined at Broken Hill in 1913 was 1,744,177 tons, an increase of 104,518 tons over 1912.

The first run at the new Cam & Motor 500-ton mill in Rhodesia, resulted in the treatment of 10,693 tons yielding \$7.58 per ton.

Dredges in New South Wales in 1913 recovered gold and tin worth £104,177 and £239,958 respectively. Since 1900 the totals have been £3,097,977 and £1,513,026.

An unusual arrangement of shafts is at the Messina copper mine, Transvaal. For several reasons, two main shafts have been sunk within 50 ft. of one another.

Gasoline is extracted from natural gas by two stages of compression of the gas to 350-lb. pressure, the yield being from 1½ to 4 gal. per 1,000 cu. ft. of gas treated.

Ore broken in the Broken Hill South mine in the latter half of 1913 was 97.3% by contract, 0.2% by wages, and 2.5% by development work. Miners earned from \$4 to \$4.76, and trammers from \$3.20 to \$3.46 per 8-hr. shift.

Actual Recovery at the sand and slime plants of the Ooregum mine, India, in 1913 was 70 and 95% respectively. Consumption of cyanide was 0.48 and 0.78 lb.; caustic soda, 0.71 lb., and zinc, 0.08 and 0.21 lb. per ton respectively.

Analysis of crude oil refined by the Midwest Oil Co., at Casper, Wyoming, is as follows: gasoline, 18.92% at 62°B.; naphtha, 2.75% at 52°B.; kerosene, 24% at 43°B.; mineral seal, 3% at 37°B.; gas oil, 17.5% at 35°B.; wax oil, 15% at 30°B.; and tar 16 per cent.

Reverberatory furnaces at the Steptoe Valley plant, Nevada, had a capacity of 481 tons of charge per day in 1913, against 371 in 1912, and 262 in 1911. The larger furnaces have not shown a reduction in the oil ratio, but show better costs on account of a large tonnage and less labor required.

Many miners and millmen have an idea that the porphyry copper ores of the great American mines con-

tain no precious metals. In treating such large tonnages, these certainly add to the revenue. During 1913, the Nevada Consolidated treated 3,139,137 tons of ore averaging 0.013 oz. gold and 0.034 oz. silver per ton. The recovery was 12.32c. per ton for both metals, with an extraction of 43.87 and 57.83% respectively. The total revenue from gold and silver was \$557,987.

Several methods are available for the purpose of preventing bullion from adhering to the ingot mould into which it is poured. The mould may be oiled with a light oil and any excess wiped away, or the inside of the mold be chalked. Perhaps the surest and simplest way is to invert the mould and rest the extreme edges on a couple of bricks, and light a small wad of oily waste underneath. In a short time the inside of the mould will be evenly coated with lampblack, which forms an excellent protection against adhesion of metal to the mould.

Ordinary valves or cocks are unsuitable for use in connection with the regulation of the underflow of settlers or classifiers. A preferable arrangement is to follow a valve, capable of opening to the whole width and shape of the discharge pipe, with a Bunsen valve. This latter consists of a short length of rubber-canvas hose fitted with a clamp. During operation the main valve is open and the rate of flow regulated by the Bunsen valve. In reducing the flow by means of the latter contrivance the hose is restricted in cross-section, but no sharp edges are formed which would, if present, favor the accumulation of solid material and possibly result in a chokeage of the outlet. The main valve is useful at times when it is necessary to entirely close the underflow for the purpose of repairing the Bunsen valve, or for other reasons.

A transparent liquid, having a specific gravity which may be regulated, and which may be made to exceed that of quartz, is of value in the preliminary work which is incidental to the treatment of most ore. Such a liquid may be made by saturating a small amount of water with potassium iodide. Mercuric iodide is then added in small quantities at a time, and as long as it dissolves. When a point of saturation is reached with the mercuric iodide, the solution is again in a condition to take up more potassium iodide. The addition of potassium iodide and mercuric iodide is then repeated in the sequence described until the desired specific gravity is reached. A sample of the ore under examination, and ground to various degrees of fineness, may be tested in a small test-tube with the liquid described. If the solution is correctly proportioned, the quartz will float on the surface of the liquid; middling containing, say, quartz and pyrite, will remain suspended according to specific gravity; and the heavier mineral will sink to the bottom. A magnifying glass will then afford a means of rapidly arriving at a conclusion with regard to the probable effect of finer crushing, and a reliable forecast of concentration results may be made.

American Electrochemical Society Meeting

[For metallurgists interested in copper, perhaps the most significant paper read before the recent meeting of the American Electrochemical Society was the address by Mr. Smith, in which was discussed frankly and fully the negative as well as positive results of the work done in perfecting a leaching process at Chuquicamata. The mine has already been described in the *Press*. We give below, with only incidental condensation, Mr. Smith's paper discussing the metallurgy.—EDITOR.]

LEACHING AND ELECTROLYTIC PRECIPITATION OF COPPER AT CHUQUICAMATA

By E. A. CAPPELEN SMITH

The Chuquicamata copper mine is at Chuquicamata, a station on a branch of the Antofagasta and Bolivia railroad, in the province of Antofagasta, Chile, between 22 and 23° south latitude. Chuquicamata is 165 miles by railroad from Antofagasta, and 82 miles in a straight line from the coast, at an altitude of 9500 ft. above sea-level. The deposit has long been known as the atacamite deposit of Chile, and for many years past has been mined by the natives. As evidence of their operations, there are found in the old workings many stone utensils such as hammers, and even mummies.

The deposit consists of brochantite, contained in the cleavages of granodiorite, mixed in part with chalcantite and to some extent with atacamite, and associated with a deposit of salt. A small amount of *caliche* containing nitrates is also present in the upper layers of the orebody.

The so-called *Ilampera* orebody extends for a distance of approximately 8000 ft., with an average width of about 500 ft. Throughout the whole length of the deposit numerous adits have been run and a very large quantity of ore has been left on the dumps from these tunnels. From the adits, raises have been made almost to the surface, leaving in places a shell over the workings 8 to 12 in. thick. A few shafts have also been sunk in the ore deposits, the deepest one to a depth of 110 metres.

ACQUISITION AND DEVELOPMENT OF THE PROPERTY

The property was acquired by Albert C. Burrage, of Boston, who, in connection with the firm of Messrs. M. Guggenheim's Sons, formed the Chile Exploration Co., which Company now owns the property. The property has been explored by churn-drilling, which has developed an orebody in excess of 200,000,000 tons. Most of the drill-holes, however, were stopped while the bottom of the hole was still in ore.

The general strike of the orebody is north and south. Lately a number of drill-holes have been sunk at a considerable distance west of the *Ilampera*, and after going through from 300 to 400 ft. of capping chalcocite, and chalcopyrite have been found, giving indications of a very materially increased tonnage over that reported up to date. In the *Ilampera* zone, of the 200,000,000 tons of ore so far developed, approximately two-thirds is brochantite and one-third sulphides. No change in the formation has been shown, even in the deepest drill-holes, the ore still appearing to be in the cleavages of the granodiorite. The lower drill-holes show primary ore. From the amount of ore developed and indicated, it appears that the Chuquicamata mine is probably the largest copper deposit known today.

It was generally assumed that this large and well-known deposit of ore was atacamite, and as such could not be treated at a profit by any of the established methods: first, on account of the highly silicious nature of the ore and the absence of sulphides and water, and, second, on account of the volatilization of the copper chloride in smelting. It was demonstrated that the mineral was not atacamite (oxy-chlo-

ride) but brochantite (oxy-sulphate), and that mixed with the brochantite in the upper parts of the orebody was a deposit of salt. The brochantite, being an oxy-sulphate of copper, is insoluble in water, but very readily soluble in dilute sulphuric acid. It was therefore evident that the way to treat the brochantite orebody would be by wet methods.

PRELIMINARY EXPERIMENTS

About 600 tons of the oxidized ore, representing, as nearly as could be judged, a fair average of the oxidized orebody, have been shipped to New York for experiment on a small scale. At first, tests were run on a very small scale, and gradually—as promising results were obtained—on a somewhat larger scale, treating about two tons of ore per day. The average content of the ore thus treated was somewhat in excess of 2% copper. The main problems which presented themselves for solution were: (1) the solubility of the copper minerals in sulphuric acid; (2) the amount of chemicals required as dissolving agents; (3) the amount of impurities which would enter the solutions; (4) the precipitation of the copper from the solutions obtained.

The principal developments in the solving of these problems may be briefly summarized as follows:

1. *Solubility of the Mineral*.—Experiments conducted on a small scale disclosed the fact that the copper-bearing mineral was very readily soluble in a cold dilute sulphuric acid solution, and that only comparatively coarse crushing would be required.

2. *Chemicals Required*.—After prolonged experiment, it was found that the ore yielded enough sulphuric acid, from the decomposition of the copper sulphate present in the brochantite, to more than make up the losses in sulphuric acid in the operation. The losses of acid occur mainly in two stages—first, the loss due to dissolving other components besides copper from the ore; and, second, due to wasting of solutions through discarding of the tailing.

3. *Impurities Entering the Solutions*.—Experiments extending over a long period of time have shown that no deleterious amount of impurities will accumulate in the solution, other than the chlorine derived from the salt deposit mixed with the mineral in the upper parts of the orebody.

4. *Precipitation of the Copper*.—The experiments conducted in our experimental plant have shown conclusively that electrolytic copper of the highest grade can be produced from the sulphuric acid solutions obtained.

EXPERIMENTAL LEACHING

After completing a number of leaching tests on a laboratory scale, and after running a number of tests with 100 kilos of material each, experiments were made on a larger scale, and a plant was built of sufficient size to treat two tons of ore per day. In this plant there have been treated 131 charges of ore, and it has been run entirely as a self-contained unit; leaching the ore, washing it, purifying and electrolyzing the solutions obtained, and leaching the following lots of ore with the electrolyzed solution from previous charges.

In this plant were treated ores representing the general character of the oxidized orebody at Chuquicamata; some high in copper, others low in copper; some high in impurities, others low in impurities; and enough runs were made to test the method on both high and low-grade ores, and on ores containing large amounts of salt as well as smaller amounts of salt, this being the principal impurity in the orebody. The salt deposit, however, is confined to the upper 50 ft. of the orebody, and principally to the first 25 feet.

In order to make sure that the method should be tested under the most adverse conditions, the same solution was used

over and over again for the treatment of the 131 charges of ore, only setting aside enough solution to allow for the excess acid. A complete analysis of this solution was then made and showed the following contents:

| | Grams per litre. |
|--|---------------------|
| Cu | 50.44 |
| Fe | 3.71 |
| Mn | 0.07 |
| P | 0.06 |
| As | nil |
| Sb | nil |
| CaO | 0.80 |
| MgO | 3.32 |
| Al ₂ O ₃ | 1.61 |
| Na ₂ O | 21.60 |
| K ₂ O | 5.00 |
| SO ₃ | 122.75 |
| Cl | 11.52 |
| Free acid (as H ₂ SO ₄) | 28.00 |
| Total solids on ignition | 189.40 |
| Nitric acid | 4.00 |

The results obtained when using the solution which had previously treated 131 charges of ore were just as good as the results with the solution made from sulphuric acid and water. In other words, the accumulation of impurities has been proved to have absolutely no effect whatever on the results obtained. The average extraction obtained in this 2-ton plant was 90.99 per cent.

Following the experiments in the 2-ton plant, a leaching tank was built of concrete, lined with mastic asphalt, having a cross-section of 4 by 6 ft. and 15 ft. deep, holding 15 tons of ore, this allowing the use of the full height of ore column since adopted for the plant now building at Chuquicamata. [See *Mining and Scientific Press*, April 11, 1914, p. 620.] The question to be decided was whether it was feasible to leach the ore in tanks of this depth. Extensive experiments gave results confirming those obtained in the smaller tanks.

A wooden filter bottom with cocoa matting on top has been employed in the 2-ton tanks and in the 15-ton tank, although a great number of tests were made without any filter bottom, simply placing a piece of cocoa matting over the outflow pipe. All tests were made without applying any extraneous heat. The washing of the ore was by the so-called 'piston' method, with a final water wash, and the tailing discharged contained an average of about 12% moisture, and about 0.04% water-soluble copper.

EXTRACTIONS OBTAINED

The leaching results obtained up to date are as follows:

| | Per cent. |
|---|-----------|
| The average extraction while treating the ore in lots of 100 kg. each was | 90.62 |
| The average of 131 charges treated in the 2-ton plant shows an extraction of | 90.99 |
| The average extraction obtained in the 15-ton tank, while treating 25 charges leached to date, has been | 90.96 |

These results are based on the weight and sampling of the ore as charged into the tanks, and the weight and sampling of the residue discharged from the tanks.

By combining all of these results and taking the copper content based on the weight and sample of the ore treated, as against the copper produced in the electrolytic tanks in the form of cathode copper, together with the copper held in solution as copper sulphate, the extraction was 89.6%.

AMOUNT OF CHEMICALS REQUIRED

After having supplied the amount of sulphuric acid required to start the operations, it was found that not only was no further acid required, but that excess acid was produced from the sulphuric acid contained in the ore itself, to such an extent that an actual gain is shown of approximately 9 lb. of

acid (H₂SO₄) per ton of ore treated. In other words, it will be necessary to discard an amount of solution equivalent to this gain in acid in order to prevent the acid from accumulating in the process. This gain in acid was made while treating an ore averaging a great deal higher in salt than even the average of the upper layers of the orebody at Chuquicamata will show. As the greatest loss of acid is in forming sodium sulphate, I believe that a still larger gain in acid will be shown when treating the average orebody.

IMPURITIES IN SOLUTION

Of the impurities accumulating in the solution, the principal elements, outside of the chlorine present, are nitric acid, alumina, iron, and alkali salts. After more than a year's work with the same solution, discarding only enough solution to take care of the excess acid, the following impurities were present:

| | Grams per litre. |
|--------------------------------------|---------------------|
| Fe | 3.71 |
| Mn | 0.07 |
| As | nil |
| Sb | nil |
| CaO | 0.80 |
| MgO | 3.32 |
| Al ₂ O ₃ | 1.61 |
| Na ₂ O | 21.60 |
| K ₂ O | 5.00 |
| Nitric acid | 4.00 |

This amount of impurities is insignificant so far as their effect upon the leaching and electrolysis is concerned. The main impurity in the solution is the chlorine obtained from the salt in the upper part of the orebody. It was at first thought desirable to electrolyze direct the solution containing the chloride, and it was found perfectly feasible to do this in covered electrolytic tanks, maintaining a slight vacuum so that the chlorine gas was all drawn off through fans. However, it was also proved that only a part of the chlorine was eliminated in this manner and that an appreciable quantity was deposited with the cathode copper in the form, probably, of cuprous chloride.

Various methods of precipitating cuprous chloride were tried, and finally shot copper, placed in a revolving drum, was adopted as the most satisfactory method. The cuprous chloride, forming on metallic copper, sticks tightly to the copper shot, and it was found necessary to present continuously clean surfaces of copper in order to maintain an effective precipitation. After trying out several methods, it was decided that the best apparatus for this purpose would be revolving drums similar to tube-mills, through which the solution would be passed in contact with the shot copper contained in the drums, as in this way the copper, rubbing against itself, continuously presents a clean surface. Precipitation with cuprous oxide was also tried and worked very well except that the efficiency of the copper in this form as a precipitating agent was found to be very much lower than that of metallic copper, even allowing for the theoretical difference.

The cuprous chloride produced may be treated in several different ways. It is now intended to filter-press the settled cuprous chloride, mix the filter-press cakes with limestone and coke, and smelt the product thus obtained, producing metallic copper and calcium chloride as a slag. A number of experiments have been conducted with this mixture to establish the reaction, and it has been found that a very liquid slag of calcium chloride is produced containing a very small amount of copper, and that in this manner it is perfectly feasible to smelt the cuprous chloride without any loss by volatilization. Some small-scale experiments have also been made looking to the electrolytic treatment of the cuprous chloride, and later on it may be possible that this latter method will be adopted, if found more profitable, in preference to the smelting method.

PRECIPITATION OF THE COPPER

The solution, freed from its chlorine content, is now electrolyzed, using insoluble anodes, and ordinary copper cathode starting sheets. After a vast amount of experimenting, it was decided to employ an insoluble anode made of magnetite. Various other anodes have been tried with more or less success, but after having investigated all the possibilities, it was decided to use magnetite anodes. Experiments with these anodes have extended over about a year and a half, and no material amount of chemical wear on the anodes has been found. The magnetite anodes which have been adopted are manufactured by a secret process by the Chemische Fabrik Griesheim Elektron of Frankfurt, Germany. The nature of the material naturally gives a brittle anode. However, as it will not be necessary to handle the anodes after they are installed in the tanks, this is not a very decided drawback.

At first a number of difficulties were encountered in the efforts to secure an even current distribution and proper suspension of the anodes, but all of these obstacles have been overcome and it is believed that a very serviceable anode has been developed. The anodes themselves are hollow castings with a wall thickness of approximately $\frac{1}{4}$ in., and have a thin electro-plated copper deposit on the inside. As I am not myself familiar with the methods employed in the manufacture of these anodes, I am unable to give any further information on this point. I can only state that after months of continuous operation the anodes have been found entirely satisfactory for their purpose.

The copper cathodes produced from the electrolysis are of the usual quality of cathode copper—in fact, a little better—as in this particular case no arsenic or antimony, usually the most deleterious impurities in cathode copper, is present in the solution. The solution will enter the head tank of the electrolytic system containing approximately 5% copper and $2\frac{1}{2}$ to 3% free acid, and will leave the last tank of the cascade containing about 1.5% copper and 8 to 9% free acid. Within these limits it is always possible to produce a good hard cathode, equal to or better than the usual standard. The electrolytic tanks used during the experiments were made of concrete lined with mastic asphalt.

DESIGN OF PLANT NOW BUILDING AT CHUQUICAMATA

On account of the very large orebody already developed at Chuquicamata, the first unit of the plant now building has been designed to treat about 10,000 tons of ore per day. The electrolytic refinery will have a capacity of about 335,000 lb. of copper per day. The ore will be mined by steam-shovels, practically no stripping being necessary. The ore will be transported to the mill, distant about $2\frac{1}{2}$ miles from the mine, in standard American gage railroad cars of 60 tons capacity each.

Arriving at the plant, the ore will first pass through gyratory crushers, thence through 48-in. Symons disc crushers, and finally through Garfield rolls until a product is obtained of about $\frac{1}{4}$ -in. mesh. The ore will be carried on conveying belts from the crushing plant, after sampling, to the leaching vats. Each of the leaching vats has the following dimensions: 110 ft. wide, 160 ft. long, and 16 ft. high. The leaching vats, six in number, will be placed end to end. The belt delivering the ore from the crushing plant will be discharged into the leaching vats with the aid of an electric traveling bridge, spanning, and traveling the entire length of, the leaching tanks. The leached and washed residue will be removed from the leaching tanks by a 15-ton grab bucket traveling on an unloading bridge, and, after sampling, will be delivered upon a conveying belt for disposal to the tailing dump. The tanks are being built of heavily reinforced concrete, and will be lined with mastic asphalt $1\frac{1}{2}$ in. thick. This tank lining has been developed by the Vulcanite Paving Co., of Philadelphia, and consists of a specially refined Trinidad asphalt mixture, to which is added crushed quartz or granite.

In the experimental plant, where this lining has been in use for considerably more than a year, both in the leaching and electrolytic tanks, absolutely no difficulty—not even a single leak—has developed. The material has been tested at a temperature of 50°C. without finding any signs of softening, and as this is far beyond the range at which it is intended to operate, tests at higher temperatures have not been made, although the temperature limit, so far as softening is concerned, will probably lie somewhere between 50 and 70°C. Tests have also been made to try the strength of this material from a physical standpoint, and in one case a 250-lb. cathode was elevated about five feet above the bottom of the tank and then dropped in such a way that one of the sharp corners of the cathode hit the bottom of the mastic asphalt lined tank. In this case, a piece of the lining about $\frac{1}{8}$ in. thick and 2 ft. in diameter was broken away, and as far as could be seen the tank lining was just as good as ever. The material has been tested in strong and weak acid solutions, and found to be absolutely unattacked.

From the bottom of the leaching tanks the solution will be removed through eight 6-in. openings equally distributed over the tanks. A filter bottom, consisting of two layers of 2-in. planks with a layer of cocoa matting between, will be employed. This filter bottom will be raised 4 in. above the bottom of the tank. For the main solution circuits, 9-in. and 16-in. lead lined iron pipe will be used. Open boot horizontal centrifugal pumps, made of type-metal, will be used for pumping the solutions. The pumps will have a capacity of 550 cu. ft. per minute, elevating to a height of 60 ft. In the leaching plant, the cycle of operation will require approximately six days, of which one day will be occupied in filling the tank, two days in leaching, two days in washing and draining, and one day in discharging.

The solutions will be conducted to the leaching tanks by gravity from nine solution-storage tanks placed above the leaching tanks. The dimensions of these solution storage tanks are as follows:

Two tanks, 12 by 130 by 150 ft.
Seven tanks, 12 by 70 by 150 ft.

From the strong-solution tank, the solution will flow by gravity through the dechlorinating plant, consisting of twenty-one 30 ft. long by 4 ft. inside diameter revolving steel drums lined with earthenware. These drums will be half full of shot copper. From these drums the solution, containing the cuprous chloride in suspension, will flow to seven Dorr thickeners made of concrete and lined with mastic asphalt. The clear solution overflowing will travel by gravity to the electrolytic refinery, while the thickened cuprous chloride, together with approximately 1% of the original solution, will go to filter-presses.

The electrolytic refinery will consist of 510 electrolytic tanks of the following dimensions: 19 ft. long, $3\frac{1}{2}$ ft. wide, 4 ft. 10 in. deep. They will be made of concrete, lined with mastic asphalt, and will be set through the floor, having inspection aisles underneath and a concrete working platform between the rows of tanks. The tank-house will be of concrete and steel construction. Of the 510 tanks, 30 will be used for making cathode starting sheets, and the rest, 480 tanks, will be used for electrolytic deposition of the copper from solutions. The tanks will be arranged in five electrical circuits, with 96 tanks to a circuit, and will be divided into 30 solution circuits, the solution in each circuit flowing through 16 tanks placed *en cascade*.

The anodes, made of magnetite, will be 5 in. wide, 2 in. thick, and 4 in. long, placed five to a bar. The cathodes will be 3 ft. wide by 4 ft. deep. The spent electrolyte, containing about 1.5% copper, will be pumped back to the storage tanks to be used for leaching subsequent charges of ore. The cuprous chloride from the dechlorinating plant will be smelted and cast into shot copper for use in the dechlorinating drums.

JOPLIN, MISSOURI

OPERATORS ORGANIZE TO IMPROVE SANITARY CONDITION OF MINES.

—NEW PROPERTIES OPENED BY THE ST. JOSEPH, T. COOPER, PITCHER LEAD, AND OTHER COMPANIES.

Operators have organized to prevent the spread of contagious diseases in the mines. Miners' consumption has caused many deaths throughout the district in recent years. Richard Polehmus, field manager for the American Zinc, Lead & Smelting Co., who left the Joplin district several years ago to look after the Company's holdings in Tennessee, returned for a few days in April and addressed a meeting of operators who were gathered to discuss plans for improving the sanitary condition of the mines. "Out of hundreds of men employed at the Company's mines five years ago, less than 50% remain," said Mr. Polehmus, "and new workmen have taken their places; the old boys are either gone to their reward or are invalids for life." The first important step taken as a result of the coöperation of producers will be the

Cooper & Co., who hold a lease of the Johnson land, northwest of Joplin. The operators are interested in the Joplin-Kentucky mine on the St. Louis-Joplin Lead & Zinc Co.'s property, adjoining the Johnson land on the southeast. They have tested their Johnson property lease with several drill-holes, 'pay dirt' being encountered from 140 ft. down to about 200 ft., with some lead in the upper ground, into which orebody the concern is now breaking in a new shaft which is being sunk. The lead ore carries a high grade of galena. A steam hoist is used. The shaft will be continued down to the blende formation.

The Pitcher Lead Co. is conducting a quiet drilling campaign on 2000 acres of land at Miami, Oklahoma. Although several dozen drill-holes have been sunk, the Company has given out very little concerning its discoveries. Operators on the ground report fairly good blende and galena. The field of activities is in a virgin part of the Miami district. Five drill rigs are at work.

A coal vein is being worked by John Newlin and associates, who hold a small lease on the American Zinc, Lead & Smelting Co.'s land at Midway Camp, northeast of Joplin. The coal is found at 28 ft. It was blocked out at several points by drilling. Zinc ore is found beneath the coal. The operators will use their own fuel in operating their hoist

GENERAL VIEW OF JOPLIN DISTRICT BETWEEN WEBB CITY AND ORONOGO.

use of sprayers in drilling hard ground. Particles of flint rock, breathed into the lungs of the workmen, have caused the majority of cases of tuberculosis. Another step will be the introduction of individual canteens to take the place of the old-style water keg, from the bung-hole of which everyone drank regardless of the nature of any particular malady from which he might be a sufferer.

Mill No. 1 of the American Zinc, Lead & Smelting Co. at Carterville, Missouri, has resumed operations after a shut-down of several months. Three of the Company's four plants at Carterville are now in operation; ore containing about 2% blende and lead is treated, the recovery from the three plants now in operation being about 600,000 lb. of blende concentrate and 180,000 lb. of lead concentrate per week. The Company ships most of its zinc output to its own smelters.

The St. Joseph Mining Co. is developing a new property on a 40-acre lease of the Connor land, northwest of Joplin. The lease adjoins the Dundas Mining Co.'s lease on the east. Three drill-holes on the St. Joseph ground showed blende and galena from 90 to 208 ft., and a shaft is now into ore at a depth of 125 ft. In the Company are David M. Sayers, of Joplin; J. W. Grounds, of Kansas City, Missouri; and J. M. Legris, of Kankakee, Illinois. A steam hoist has been installed and mining operations commenced. The formation is typical of the 'Chitwood' district, the blende and galena crystals occurring in a conglomerate mass of chert, closely cemented to flint boulders and to 'sugar rock.' Above the ore formation is a substantial cap-rock of limestone.

A most promising property is being developed by Thos.

and pumps while they sink to the lower ground for ore.

The Durston Mining Co., west of Galena, is handling surface accumulations of several decades. A mill of 250-ton daily capacity has been constructed on the McElroy land, and a number of narrow-gage tracks run in various directions from the mill to reach the many old dumps on the ground. Shallow mining on this land has been in progress for over 25 years. As hand-jig plants were used almost exclusively in the early days of that camp, a heavy percentage of blende, in the large boulders, was lost. These are being milled and the recovery is averaging more than 2%. Also the operators are skimming the entire surface of the lease for a depth of 8 to 14 in., this top part being 'made' ground resulting from the accumulation of sediment for many years. This dirt as it is now being worked yields about 2% in blende concentrate.

ISABELLA, CALIFORNIA

WORK AT THE MAMMOTH MOUNTAIN MINE, KERN COUNTY.—THE KEYS AND BIG BLUE MINES.

The erection of a complete 10-stamp mill has just been completed at the Mammoth Mountain mine, 4 miles southwest of Isabella, Kern county, and is now in operation. At present, however, only one shift can be operated, owing to the shortage of water; that available being drainage from the mine, which is only equivalent to half a miner's inch. The water is lifted from the shaft by a Dow triplex motor-driven pump and is conducted through the main adit to a

large tank, above the mill, with a capacity of 22,000 gallons. A new concentrating table is on the ground, but has not yet been installed, it being thought unnecessary, owing to the low percentage and grade of the pyrite in the ore. The mine is equipped with a 50-hp. motor-driven Erie No. 4 compressor and Leyner and Ingersoll machine-drills. An electric hoist is used in the shaft. Ore is being broken in the stopes above the 400-ft. level, and a cross-cut is being driven from the 600-ft. level, the present shaft bottom, to the vein. The vein averages about 4 ft. in width and is quartz, sometimes intermixed with an altered granite, the wall rock being granite. Above the 400-ft. level the vein divides, about three feet of profitable ore being on the hanging wall. On the foot-wall the dip of the vein alters about 5°, and a strong body of red oxidized quartz, impregnated rather freely with arsenical pyrite, continues to the surface. This foot-wall vein is being stoped with machine-drills, the shrinkage system being employed. The vein strikes northeast and southwest approximately, the hanging wall vein dipping 85° to the southeast, the foot-wall vein dipping about 80°. The hanging wall vein has been worked profitably to the 300-ft. level, but has been temporarily abandoned, so much ore of better value being in sight. Driving ahead on the 400-ft. level is under way, and at a point 1500 ft. along the strike of the vein and 500 ft. from the shoot which is now being stoped another shoot has been cut, which will be stoped as soon as the mill is in shape to work three shifts. A. G. Kealing is in charge of the property.

At the Keys mine, nearly a mile northwest of the Mammoth, several men are developing and stoping ore. The 5-stamp mill is running steadily on a fair grade of ore. The mine is equipped with a small compressor and machine-drills, but at present all of the stoping is done by hand. The manager, Mr. Reid, has been at the property for about a month.

The Big Blue mine, near Kernville, shows signs of revival. A small crew of miners is at work repairing the drainage adit, and it is rumored that active operations will be commenced about May 1. The manager, Mr. Long, who has been absent in the East for some time, is now at the mine. This property is equipped with modern machinery, although the old 80-stamp mill on the Kern river has been dismantled.

TORONTO, CANADA

WORKMEN'S COMPENSATION ACT.—THE JUPITER MINE.—DOME RETURNS.—BUFFALO PEOPLE INTERESTED AT PORCUPINE.—CONSOLIDATION AT COBALT.—CANADIAN MINING & EXPLORATION CO.—CREIGHTON NICKEL MINE.

The new Workmen's Compensation Act for Ontario will probably be in force by next November, and in any event it would become operative on January 1, 1915. The bill is now up before the Ontario legislature and has passed its second reading. As it is not a question of party politics and has the support of both sides of the house, there should be no difficulty in having it become a law. In spite of the protests made by some of the interests affected by this bill, it is practically the same as originally drafted by Sir William Meredith. All of the interests affected by the new act are in favor of compensation itself, but they object to some of the terms and clauses of the act. They consider the amount of compensation too high, and the number of employees embraced altogether too large, for a legislation which has not yet been tried. This proposed act is more comprehensive and embraces a greater variety of employees than any similar legislation in the world, but the Canadian Manufacturers' Association and others would prefer to see this legislation tried out on a somewhat smaller scale at first. The government will include in the estimates an annual payment of \$100,000 for the administration of the Compensation Commis-

sion, but it is doubtful if this sum will cover the total cost of administration, and in that event the industries covered by the act will have to bear the balance of the cost.

The Jupiter mine in Porcupine is now under control of the McKinley-Darragh company of Cobalt, and operations under the new management will be started in a few days. According to the terms of the deal which have been ratified by the McKinley-Darragh shareholders, a new company, with a capitalization of \$2,000,000, will be formed to take over the assets of the Jupiter company. The present shareholders will receive one share of stock in the new company for every two shares turned in. This will leave 1,000,000 shares in the treasury, which will be taken by the McKinley-Darragh company at 12c. per share. The purchasers agree to spend \$30,000 by August 1 in developing the property, and should results be satisfactory they will then pay off the \$50,000 bond issue which is outstanding, and provide additional working capital to the amount of \$40,000. P. A. Robbins, of the Hollinger mine, made a report on the property some time ago for the Jupiter shareholders, and it is understood that he estimated the net value of the ore after deductions were made for working costs, at \$120,000. Out of this amount, however, funds would have to be provided for the building of a mill. The property is an excellent prospect, and development to date has by no means exhausted its possibilities.

The Dome report for February shows that the mill treated 12,010 tons and produced bullion worth \$69,000. The mill ran 89% of the possible time. This smaller tonnage is due to February being a short month, and also to a shut-down on account of power troubles. The drop in the grade of the ore was considerable, the average value recovered being \$5.75, as compared with approximately \$8 per ton for the preceding month. The report for March has not yet been published officially, but will show a production of about \$86,000 from 15,000 tons of ore. This is the highest monthly tonnage ever treated at the Dome.

Buffalo interests have recently made offers for several small properties in the vicinity of the Dome mine. These consist of the Porphyry Hill, which was formerly a part of the Preston East Dome holdings, the Little Pet, and the Fogg properties. All of these adjoin, and they have small rich veins of narrow width. An offer of \$40,000 has been made for an 80% interest in the Porphyry Hill and \$25,000 each for the same interest in the other two properties. These deals have not yet been officially endorsed by the owners.

At a meeting held in Toronto on April 14, a consolidation of the interests in the Cobalt Townsite, Cobalt Lake, City of Cobalt, and Cobalt Townsite Extension companies came before a general meeting of the Cobalt Lake shareholders. A poll of the shareholders of some of these companies, held a short time ago, resulted in a large majority in favor of amalgamating the properties. Some of the shareholders of the Cobalt Townsite company were, however, by no means favorably disposed to the scheme, as they thought that the new company proposed to pay too high a price for some of the other properties. The estimated value of these various properties was £1,600,000, and the net annual income is estimated at 17%. The proposed capital of the new company is \$7,500,000, and shareholders in the various properties will receive shares in the new company in return for shares in the present companies.

At the annual meeting of the Canadian Mining & Exploration Co., held recently, the report of the president, Ambrose Monell, showed that during the year 109 properties were given preliminary and final examinations. Of these, 34 were more or less developed mines, and 75 were prospects. Of the mines, 8 would have been satisfactory if the terms had been suitable and the Company would have been prepared to develop 9 of the prospects under somewhat different conditions. The hope was expressed that negotiations with regard

to some of these properties would result in their being acquired by the Company. Two properties on the Pacific Coast are being held under option, and negotiations are under way for obtaining several others. The profit and loss statement for the year showed a gross income of \$133,799, of which \$78,000 was expended, leaving a balance of \$55,500 to be carried forward.

Recent developments at the Creighton nickel mine, in the Sudbury district, have shown a much larger tonnage of ore than was expected by the management a year ago. The ore from this mine is the highest grade ore being produced in any quantity in the Sudbury district today. At the No. 3 mine, where it is stated that approximately 40,000,000 tons of ore has been developed by underground workings and diamond-drilling, extensive plans for the production of ore were under way, but on account of the higher grade ore being produced in the Creighton and the large tonnage shown by recent development, it has been decided to do only a limited amount of work at No. 3 in order to carry out certain development and provide a small tonnage to flux the Creighton ore.

NEW YORK

MERGING OF THE ANACONDA AND INTERNATIONAL SMELTING COMPANIES.—THE A. S. & R. CO. IN MEXICO.—MEXICAN COPPER.—UTAH COPPER.—ALASKA EBNER GOLD MINES COMPANY.

The Mexican situation has divided interest during the week with the absorption of the International Smelting & Refining Co. by the Anaconda company. The move is not an especially startling one, for the International is already a very close relative of the Anaconda, since 43% of its stock is held by the United Metals Selling Co., which is controlled by the Amalgamated Copper Co., which owns the Anaconda. E. P. Mathewson, the manager of the Anaconda smelting plant at Anaconda, was for some time general manager of the International, and was last year succeeded in that office by W. D. Wraith, who had been smelter superintendent at Anaconda. The absorption of the New Jersey corporation by the Anaconda is to be carried out by an exchange of stock on the basis of 3.3 shares of Anaconda for 1 share of International, and a special meeting of International stockholders is called for May 26 to consider this proposal. The Anaconda stock is \$25 par and quoted at \$33, while the International is \$100 par and quoted at \$105, so that the exchange represents the present relative positions of the two shares. Only about 330,000 shares of Anaconda will be required to take over the International, and as there are 1,667,500 of Anaconda shares still in its treasury, this will not make any very great inroad on its treasury stock. The International has had an interesting history, since when it started work at Tooele it was expected that it would be a large copper smelting plant. The expected amount of copper ore never materialized and the copper furnaces have never operated at more than a fraction of their capacity. Meanwhile an unexpectedly large supply of lead ore developed, and the International has become a considerable lead producer, owning as well a large copper refinery near Chicago. Now that plans are well advanced for the new smelter at Miami, Arizona, to handle the concentrate from the Inspiration and Miami mills, the International will become an important copper producer again, and its absorption by Anaconda is the more logical.

Recent developments in Mexico are of intense interest to mining men everywhere. Perhaps the greatest interest is that centred around the operations of the American Smelting & Refining Co., which owns many mines, smelters, and railroads in Mexico. The operations of several of these have been either interfered with or completely stopped, for a good part of the time during the past year or so, but some of the plants, especially those at Chihuahua and Aguascalientes, have been kept in fairly steady operation, though at somewhat reduced

capacity. Daniel Guggenheim is quoted in a recent interview as saying that the dividends of the Company will not be seriously affected by the present situation. Ever since the trouble in Mexico developed, preference has been given to investments in this country, and work has been concentrated on the American plants. The Tacoma plant, by the way, is developing rapidly because of the recent shipments of copper ores from South America. The rates to Tacoma are somewhat more favorable from the west coast of South America than they are to the Atlantic coastboard, and as the Tacoma refinery is the only one on the west coast, it is possible to smelt there at an advantage, and produce refined copper for the western and trans-Pacific market, sending any excess to the Atlantic seaboard. It seems as though the Tacoma plant is likely, therefore, to grow considerably in importance, especially as Alaskan ores are also increasing in quantity. Another point in regard to Mexico is the possible effect it will have on the copper market, which has been decidedly dull lately. The optimists are inclined to think that the cutting off of the Mexican output will cause an increase in price, but the importance of the Mexican output may be easily overestimated. The Cananea plant has already been shut down, and its output will be off the market for a time; but it should not be overlooked that the total shut-down of Cananea only takes off the market an amount about equal to that by which the Utah Copper exceeded in March its February output. There seems little reason to believe that the decrease in copper production is likely to have anything like the effect on the market which increased buying is apt to produce. If war should actually be declared the manufacturers of ammunition would have to immediately begin to add to their present stocks, and that would mean buying more copper. On this score, it seems as though there is an excellent chance for an improved market for copper. The U. S. S. R. & M. Co. is another big organization which suffers heavily from the present situation in Mexico, as its most valuable properties are there.

The report of the Utah Copper Co. has just come out and shows a new high level of both production and earnings, even in spite of the fact that the cost of copper is given as 9.25c. as compared with 8.78c. per lb. in 1912. The average price received for the copper was also somewhat lower in 1913, being 14.98c. as compared with 15.84c. in the preceding year. The production, however, was 113,924,834, as compared with 91,400,000 lb. the preceding year, and the total net profits were \$8,513,105, as compared with \$8,450,000 for 1912. The Company made a new departure by beginning to pay off a small sum for depreciation. It will be remembered that the Utah Copper has so far deferred a certain part of its operating expenditures in order that they shall be charged off to the later operations which they would benefit. The writing off of \$507,000 is quite a small amount, but is a start in the wiping out of these capital debits, at any rate. On the basis of the present estimate, the Company has ore reserves of 332,500,000 tons, or a life of about 50 years, at the present rate of production. As the mining and milling properties and equipment are carried in last year's balance sheet at about \$18,000,000, and the deferred charges at about \$2,500,000 more, a yearly sinking fund of \$507,000 ought to take care of amortization in case the life of the mine is as long as it is hoped. For the first time in its history, the management announces that construction work is practically completed. Presumably from now on the production, which has heretofore been steadily increasing, will remain pretty steady at between 10,000,000 and 12,000,000 lb. copper per month. An interesting move is the election of W. Hinckle Smith to the Utah board. Mr. Smith has been interested in the Ely district for a long time and has been on the Nevada Consolidated board since the beginning. His election to the Utah board is another example of the tendency of all the big groups to get together, which has been so marked in the past year or two.

Some time ago I wrote concerning the internal troubles of

the company which owns the Alaska-Ebner property at Juneau, which is now under option to the United States Smelting, Refining & Mining Co. On April 22 the physical assets of the Alaska Ebner Gold Mines Co. were sold at auction, under a foreclosure suit of the Guaranty Trust Co., for \$225,000, the only bid being that of the bondholders' committee. The assets include mining machinery at Juneau; mines in Madera county, California; claims and notes aggregating \$97,000; and shares of stock of the following companies: Bristol Consolidated Mines & Smelting Co., 1,700,350; Bay Bristol Consolidated Mining Co., 199,996; Ebner Gold Mining Co., 100,000; and Humboldt Mining Co., 1000 shares. Receivers were appointed for the Company two years ago, when it was stated that the liabilities were \$2,000,000.

WASHINGTON, D. C.

THE SMOOT BILL ON MINING LAWS.—ROUGH PASSAGE FOR THE RADIUM BILL.—RESCUE WORK IN MINES DISCUSSION.

It is being generally conceded in the halls of Congress that probably the only mining legislation that has any chance to be passed this session is the Smoot bill creating a commission of three to codify the mining laws of the country. This is on the Senate calendar now, which is full of other legislation, so this bill has to wait its time until the more important legislation is out of the way. Of course, codifying the mining laws is very important work, and much needed, and the legislation could be put through in a short time; but Congress is always loth to do the easy and obvious thing. Senator Smoot, of Utah, is watching the chances for his bill, and is confident that it will ultimately pass during this session, but he is satisfied that it is a matter of 'watchful waiting' only. It is well known that if the Senate once passes the bill it will be an easy matter to get the House to pass it. The movement for a commission of five members, instead of one of three, still shows life, but Senator Smoot is averse to recalling the bill from the calendar to make this change in the bill for a larger commission, and before offering the amendment in the Senate he wants to be sure that there would be no opposition to it, lest it defeat the bill. He believes that a commission of three is better than no commission at all.

The radium bill seems to be doomed. It has been before the Senate for several days, through a special order arranged for by Senator Walsh of Montana, father of the bill. When the Senate permitted this to be done, it supposed that it was allowing just one hour for the consideration of the bill on a certain day, hoping thereby to be that courteous to the measure and its friends, and then letting it lie dormant. But the Vice-President has ruled that the Senate had arranged such a status for the bill that it must be considered every day at 1 p.m., for one hour, until disposed of. The ruling has excited the Senate considerably, as it may set a bad precedent, and the Senators have been very busy debating the 'metaphysics' of the arrangement, rather than the bill, using a great deal of valuable time that way. It is a way the Senate has, and at this writing the status of the measure is still in the plight indicated. The debate, however, has shown the degree of opposition to it, and that it is sufficiently strong seemingly to defeat the bill. It is contended that the time is not ripe for such a sweeping measure, which the bill is deemed to be. Furthermore, it is declared that the bill introduces the Government into mining, and that this is a very serious precedent indeed. The bill, therefore, is engendering votes against it on that account alone. Still further, the opposition is growing on account of the feeling that radium has yet to be found a real cure for cancer, and so, why hurry? There is also not a little complaint that the bill is a preventive against prospecting for radium, and that this is to be avoided. Of course the anti-conservation people in Colorado are especially in arms against the bill, for it spells conservation, which is not popular in Colorado mining circles.

Hearings were given in the week beginning April 19 by the House Committee on Mines and Mining, on legislation planning rescue work in mines. Among others, William Greene, of the International Mine Workers, will be heard. This legislation is probably something for the next session. The House Committee also expects to report soon on the results of its inquiry into the Colorado mine troubles. The report will suggest legislation. Little, as a rule, comes from these reports. Generally the report is on something that has ceased to exist, and in which there is no longer any public interest, consequently no imperative need for legislation, and especially legislation of a controversial kind.

ROCHESTER, NEVADA

DEVELOPMENTS IN THE BIG 4 LEASE.—Codd Lease.—Increase in Gold in Ores of the Rochester Mines Group.—Sundry Lease Work.—Proposed Railway Extension.—Placers.

The Big 4 lessees on the Rochester Mines Co.'s property have been underhand stoping the 50-ft. level, and are mining 7 ft. of good shipping ore. This ore is directly beneath the 50 stope which produced about \$100,000 last fall. In the lower levels, on the 160 ft. south, after following the shoot down along the hanging wall, a few shots were put into the foot-wall which exposed shipping ore, with the result that this has been followed upward from the bottom, and the stope shows a width in places of 14 feet.

The Codd lessees are sinking again, having installed another hoist and skip, and will connect with the main Causten level, which is 400 ft. below the apex of the main vein. The lessees are taking out good ore on the 320-ft. level north.

A notable feature of the Rochester Mines ore is the increase in the gold content with depth. At and near the surface the value in gold from the various leases, according to smelter returns, amounted to only 60 and 80c. per ton, whereas the recent shipments from the Causten lease, the lowest workings on the peak, have yielded over an ounce of gold per ton. The lower levels of the Big 4 lease also show a big increase in gold. The leases on the Rochester Weaver ground have always had a fair gold content, the first shipments from the Colligan averaging about an ounce; but these workings are all at a lower zone than those on Nenzel peak.

The No. 4 lessees in the Rochester Mines are now driving north from the main Causten level, and are down about 400 ft. The Camille Rock lessees, on the Nenzel Crown Point property, which lies to the northeast of the Rochester Mines ground, within the past few months have opened about 5 ft. of good ore which is being sorted and sacked for shipment. This lease has been hampered by surface water, which filled the shaft and workings. It is expected that a hoist and equipment will shortly be installed. The showing on this lease has greatly increased the value of this property, through which an extensive vein system runs, including the veins of the main property of the district. The Cole and Colligan lessees to the south have opened small but rich shoots of ore, and the Shea Stoker lease, also on the Rochester Weaver ground, is in very good ore from 3 to 5 ft. wide. The Boughton and the Ferri Sampson lessees on the McIntosh-Pitt ground are getting out another shipment. A lease has recently been let on the Minnehaha property, situated east of Nenzel peak, to Force and McGilvary. Lessees have been sacking and shipping float from Nenzel peak found on the ground to the west, and returns of at least \$60 per ton are expected. Recently some high-grade float, showing free gold, has been found.

It has been rumored for some time that the Nevada Short Line, running an industrial track and train service from the lower end of Limerick cañon to Nenzel, on the Southern Pacific, would extend its service to the town of Rochester, but so far nothing has been done beyond making the surveys, for which quite a camp is established.

General Mining News

ALASKA

CHISANA

All litigation connected with claims in this district has been finished at Cordova by Judge Brown. There were 16 suits from Chisana. The defendants in all these cases were the original locators of the ground. The plaintiffs were those who had made later locations, claiming the first locations to be invalid for various reasons. Twelve of the disputed locations were made by power of attorney, and it was claimed that these were invalid because the power of attorney had not been recorded prior to staking the ground. The question of citizenship was not discussed. The most important argument decided by Judge Brown was that the power of attorney need not be recorded, under the Wickersham act, prior to staking, but that the location is valid if the power of attorney be recorded and all the acts of location completed before the rights of the second locator intervene.

CIRCLE

The Circle quadrangle is described in Bulletin 538 by L. M. Prindle of the U. S. Geological Survey. The area con-

WILD GOOSE DREDGE, 23 ABOVE OPIHIR, COUNCIL DISTRICT.

tains about 17,000 square miles of well known territory, and includes the Birch Creek placer district, which is the most important.

CORDOVA

The barge *America* has arrived with 2600 tons of supplies and machinery for the Midas copper mine, which is owned by the Granby Consolidated company of British Columbia. A tramway, wharf, ore-bins, and a bunkhouse will be built. Seventy-five men are to be employed, under G. E. Smith, at the beginning of operations.

FAIRBANKS

The dredge being built by the Union Construction Co. at San Francisco for the use of Clarence Berry and associates is more than half complete. It will be shipped to Circle City for use on Mastodon creek at the opening of navigation. Announcement that the contract for the boat had been let was received with surprise at Fairbanks, but has been confirmed by the *Mining and Scientific Press*, which made the first announcement.

JUNEAU

(Special Correspondence.)—The Alaska Juneau company has had 20 stamps running since early in March, and in about another month 10 or 20 more will be at work, crushing through 14-in. screens, by passing the fines, separating a waste product on Wilfley roughing tables, and regrinding the oversize

from classifiers or screens of the Bunker Hill & Sullivan type in a Chilean mill and a Hardinge mill in competition.

The main adit of the Perseverance mine, recently connected with the shaft, is now being trimmed-up to size. The United States Smelting, Refining & Mining Co. has just cut the vein in the adit. A 5-stamp sampling mill is being erected at the mouth of the adit.

Juneau, April 14.

March returns from the mines on Douglas island are as follows: Alaska Mexican, gold worth \$46,535 from 19,698 tons of ore and 371 tons of concentrate, with a profit of \$13,743; Alaska Treadwell, gold worth \$204,463, from 83,581 tons of ore and 1572 tons of concentrate, with a profit of \$125,869; and Alaska United, gold worth \$70,702 from 37,121 tons of ore and 734 tons of concentrate, with a profit of \$9802.

The Alaska Gastineau Mining Co. will add to its power-plant equipment a 1750-kva. alternating current generator and switchboard from the General Electric Company.

ARIZONA

COCHISE COUNTY

On April 22 a fire at Bisbee destroyed 55 houses worth about \$100,000. In a short time a relief fund of \$5000 was raised for those rendered homeless.

GILA COUNTY

Additional Hardinge mills are being installed in the Miami mill. Fire destroyed buildings worth \$20,000 in Miami last week.

(Special Correspondence.)—The haulage drift on the 600-ft. level of the Inspiration mine was connected April 21, so that from now on all material and waste going to and from these lower workings will be handled through the incline instead of the Colorado shaft. The 12-compartment oil-flotation machine was started early in the week, and is now treating the material which the 8-compartment machine has been handling in the test mill.

Miami, April 22.

MARICOPA COUNTY

(Special Correspondence.)—The old Phoenix mine, 20 miles north of here, is being sampled and examined, and will probably be reopened for its low-grade gold ores. The property attracted considerable attention years ago. A 100-stamp mill was erected, but only 20 were used. Three years ago, 50 stamps were moved to the Glory Hole in Yuma county, those remaining being a monument to the work of the promoters. Phoenix, April 23.

CALIFORNIA

Oil production of 11 fields in March averaged 286,591 bbl. per day. There were 5899 producing wells. Total shipments from the districts were 8,833,769 bbl. Stocks on March 31 were 49,847,770 barrels.

PLACER COUNTY

A representative of the Guggenheim interests, E. B. Braden, has stated that within six weeks mining will be resumed on the sulphide ore in the Dairy Farm mine, 11 miles north of Lincoln. At present 100 tons per day of gossan is being extracted, and shipments of sulphide ore to the Selby smelter will be from 200 to 300 tons per day.

SHASTA COUNTY

Fire broke out on the 1200-ft. level of the Midas mine, 53 miles southwest of Redding, on April 21, and has not yet been subdued. The mine has two shafts, 600 and 1300 ft. deep respectively. Three miners were rescued by the superintendent, H. L. Waste, and J. Moore. About 100 men will be out of employment. W. H. Roberts, of Sacramento, is manager and owner of the property.

SIERRA COUNTY

There are now six regular gold producers at Alleghany,

the Rainbow being the latest on the list. The adit at this mine is in 2500 ft., and some rich ore has been opened. A new 10-stamp mill is to be erected to replace that burned last year. L. B. Woodbury is manager.

COLORADO

OURAY COUNTY

A branch of the Colorado Metal Mining Association has been formed at Ouray, with B. H. Du Prau as president and William Rathmell secretary. About 6 ft. of ore has been opened on No. 8 level, off No. 3 shaft, of the Camp Bird mine.

SUMMIT COUNTY

Lessees in the Dunkin mine, on Nigger hill, in the Breckenridge district, have extracted gold specimen ore worth \$25,000 during the first half of April. This property is owned by Leadville people, who gave a 10-year lease to O. K. Gayman, Theodore H. Knorr, W. W. Wharton, and J. A. Summer. The rich pocket was found at a depth of 500 ft. The Wellington Mines Co. shipped 18 carloads of zinc concentrate, also 65 tons of lead-silver concentrate, during the two weeks ended April 15. R. M. Henderson is manager. A busy season is expected for the Tonopah Placers, French Gulch Dredging, and other companies.

TELLER COUNTY (CRIPPLE CREEK)

From the El Oro mine, on Battle mountain, a carload daily of \$28 to \$44 ore is being shipped to the Golden Cycle mill. The April output will be about 44 cars. Additional miners are to be employed. An electric locomotive is being installed in the No. 2 working of the Portland mine. At 400 ft. in the Spicer claim, owned by the Strong company, and under the business centre of Victor, rich ore has been opened in granite. The Dante mill, on Bull hill, is producing 350 tons of ore per month. It is operated under lease by Edwin Gaylord. The Doctor-Jack Pot Mining Co. has acquired several claims of the Work Mining & Milling Co. James F. Burns, chairman of the committee in charge of the proposed extension of the Roosevelt drainage tunnel, has informed the Elkton Consolidated company's directors that \$50,000 has been raised for the work. This will do for 2600 ft. farther, the tunnel being a little smaller than the present size. Drainage would then be about 450 ft. below the present water-level in the Elkton. The work could be finished early in 1915.

James F. Burns has been elected president of the Cripple Creek Drainage & Tunnel Co. F. G. Peck, of the Portland, and John T. Milliken, of the Golden Cycle company, resigned, their places being taken by Irving Howbert and John Tait Milliken. E. M. De La Vergne, formerly of the Elkton Consolidated, also resigned. At the meeting at Colorado Springs it was decided that the tunnel should be completed to its original destination, the Vindicator main shaft. The Vindicator, Golden Cycle, and Portland companies, and other district companies, have promised increased subscriptions to the project. The credit balance is \$6000. The executive committee has been authorized to proceed with the work at once.

IDAHO

LEWIS COUNTY

The Kirtley Creek Gold Dredging Co.'s dredge, built by the Yuba Construction Co., is handling 100,000 cu. yd. of gravel per month. On an adjoining creek, the Bohannon Dredging Co. is handling about 2000 cu. yd. per day. The Bohannon Creek property consists of 3300 acres of dredging ground, which is estimated to average 25c per cubic yard. Both of these large dredges are operated by electric power supplied by the Portland Power Co. from Salmon.

Development at the Virginia Consolidated mine, near Baker, has proved ore worth \$250,000, in 6000 ft. of adits and other work. A larger treatment plant is to be erected, and probably a Lane mill will be installed.

SPOKANE COUNTY

Net profits of the Snowstorm Mining Co. for 1913 amounted to \$137,455, against \$88,778 in 1912. Ore mined was 105,674 tons, worth \$709,577, of which mining cost \$309,161, and transport and reduction, \$207,847. The Company has started to drive an adit from its workings into Missoula ground. It will be over 8000 ft. long, and cost \$80,000. An additional 1000 ft. of depth on the Missoula orebodies will be made by this work. Owing to the low price of lead, and repairs to be made to the shaft, hoist, and mill, the Morning mine, one of the Federal Mining & Smelting Co.'s properties, has been temporarily shut down. About 400 men are regularly employed. Affairs of the Stewart Mining Co. are said to be badly tangled, and further litigation is certain. Suits, injunctions, and other legal processes are being brought by William Beaudry, William A. Kerr, John W. McKinnon, and Campbell Carrington.

The Stewart Mining Co. did not pay its expected dividend on April 25, and there was a drop of 6c. per share in Spokane as a result.

MICHIGAN

Copper production of this state last year was 135,853,409 lb., worth \$21,057,278, compared with 218,138,408 lb., worth \$35,992,837, in 1912, according to the U. S. Geological Survey. Silver output was 295,173 and 528,453 oz., respectively; and ore treated, 7,016,307 and 11,411,941 tons. The reduction was due to the strike, which started in July 1913.

HOUGHTON COUNTY

During six days of the past week, the Mineral Range railway handled 73,840 tons of copper 'rock,' from the following mines: Ahmeek, 9840; Allouez, 5320; Centennial, 2280; Hancock, 2120; Kearsarge, 14,200; La Salle, 1320; Mass, 2080; Mohawk, 13,680; Osceola, 5020; Superior, 3560; and Wolverine, 10,400 tons.

MONTANA

FERGUS COUNTY

During March the Barnes-King Development Co. treated 4087 tons of ore, averaging \$10.15 per ton. The average cost for mining and milling was \$3.50 per ton. The month's profit is about \$40,000. The Company is out of debt, and has a balance of about \$125,000.

LEWIS AND CLARK COUNTY

There is quite a revival of mining activity in districts adjacent to Helena. More men will be employed at the Valley Forge, Lee Mountain, and Porphyry Dike mines in the Rimini district. At Marysville, 75 to 85 men are working at the Bald Mountain, controlled by Thomas Cruse. Development at the Piegan-Gloster, operated by the Barnes-King company, is encouraging. Six miles from Marysville is the Bald Butte, and prospecting is at an interesting stage. George Padbury is superintendent. Ore worth over \$160,000 has been opened above 300 ft. in the Franklin, in the scratch gravel district. Prospecting is under way at the Montana Copper-Silver Mining Co.'s claims nearby. The York Mining Co. is employing 48 men at Trout creek, and a mill is being erected. Probably the Spring Hill mine will be re-worked in the stockholders' meeting on May 4 decides on any action.

SILVERBOW COUNTY

(Special Correspondence.)—The Anaconda Mining Co. has contracted with Minerals Separation, Ltd., for an experimental unit for flotation. The process will be tried on the slime in competition with the roasting and leaching now under way. If it proves successful, a flotation plant will be built.

Butte, April 22.

In the dispute between the W. A. Clark interests who own

the Elm Orlu, adjoining the Black Rock, and the Butte & Superior company, concerning orebodies in the west end of the Black Rock claim, a settlement is likely to be made. Messrs. Creden, Wiley, and Finch have been making examinations for the Butte & Superior, and Messrs. Weed, Winchell, Green, and Pyle for the Clark interests.

NEVADA

CHURCHILL COUNTY

During March the Nevada Hills Mining Co. produced 5080 tons of ore averaging \$9.68 per ton, yielding \$43,469, at a cost of \$30,981. The total cash resources are \$207,676. Development covered 502 ft. during the month, at a cost of 65c. per ton.

ELKO COUNTY

Oil locations aggregating 8580 acres have been made on the low mountain range immediately south of Elko in the past two weeks. The names appearing on the locations consist of 18 Ely people, 18 Elko people, and 13 whose residences are in the east and San Francisco. This country has been a favorite one for the oil prospector, and people who have lived here for the past 15 years will remember that there have been several oil booms.

At a depth of 400 ft. in the Alpha mine, at Jarbridge, 5 ft. of ore worth over \$75 per ton, and containing 80 oz. silver, has been opened. A 5-stamp mill is at work.

ESMERALDA COUNTY

During March the Goldfield Consolidated mill treated 30,349 tons of ore, yielding a net return of \$161,286, according to the assistant general manager, J. W. Hutchinson. The total costs were \$5.80 per ton. Development totaled 2789 ft. at a cost of \$8.01 per foot. Stopping operations in the hanging wall of the old 305 stope in the Red Top-Laguna mine exposed a considerable tonnage of good milling ore. In the Clermont-Jumbo the 402-Z intermediate drift, driven south on the hanging wall vein of the old 401 stope, produced 200 tons of \$50 ore. Lessees on the Jumbo No. 2 produced 85 tons of ore valued at \$1874, from which the Company received a net royalty of \$928. On account of the preliminary expense necessary for the extraction of this ore, the net profit to the Company is largely in excess of that which would have resulted from Company operations.

LANDER COUNTY

By the recent decision of Judge Farrington, of the U. S. district court, 700 ft. of ground along Copper cañon, near Battle Mountain, is open to location as a placer district. The Glasgow & Western Exploration Co., which holds claims there, will appeal from this decision.

LINCOLN COUNTY

A 'Publicity Edition' of the *Pioche Record* gives a good deal of interesting information on the mines of this district. Names of the principal producers were given in last week's issue of the *Mining and Scientific Press*.

NYE COUNTY

Two auto-trucks are to be used in transporting ores from the various mines controlled by the Commercial Mines & Milling Co. to the War Eagle mill at Manhattan. It is the intention of the operators to make a series of mill tests, making a separate test from each of the many places where ore will be mined.

The Golden Arrow Mining Co., controlled by Eastern people, has arranged to erect a 50-ton mill and cyanide plant. Over 6000 ft. of development has been done in the claims at Golden Arrow. Mr. Kieron is manager.

The Sunset Mining & Development Co. is developing the Tramp mine, which consists of 11 claims, in the Bullfrog district. The country rocks are rhyolite, basalt, and quartz-

ose and shaly beds underlain by limestone. The contact between the rhyolite and shaly limestone is the fault plane of the Original Bullfrog-Amargosa fault, which may prove of importance to ore formation in the mine. Bonanza mountain, in which is the Tramp mine, contains a large number of faults. Each of the three principal veins in the mine is in a different fault. The ore is soft and decomposed between rhyolite walls, and the veins are from 2 to 40 ft. wide. The shrinkage system of stoping can be used, and little timber is necessary. Development to date totals about 14,500 ft. The Tramp adit, or 400-ft. level, will serve as a main haulage-level for the whole mine. Ore reserves amount to about 54,000 tons in five veins, gold content varying from \$4 to \$10.60 per ton. Equipment consists of a Hendrie & Bolthoff hoist driven by a General Electric motor, an Ingersoll-Sargent air-compressor driven by a Westinghouse motor, and five Sullivan and one Waugh machine-drills, according to a report by E. T. Hager. Tests made on the ores by F. W. Lockman show that by leaching sand and filtering slime an extraction of 90% of the gold should be made with a low consumption of chemicals, while it might pay to erect an all-sliming plant. The president of the Company, E. S. Van Dyck, has proposed the erection of a mill to treat 2000 tons per month, costing about \$30,000.

A new treatment plant is being erected for the Sunset company, most of the machinery being supplied by the Colorado Iron Works Co., which hopes to have it installed early in August. The flow-sheet is as follows: One-inch grizzly, Blake crusher, Challenge feeders, ten 1050-lb. stamps, 6-mesh screens, belt and bucket elevator, 45-in. Akins classifier, slime from classifier to No. 1 set of 7 by 20-ft. Dorr thickeners, sand from classifier to a 5 by 18-ft. Colorado Iron Works tube-mill, pulp from tube-mill over copper plates, slime from No. 1 thickeners to four 12 by 15-ft. Pachuca tanks, slime from these to No. 2 thickeners, filtration by a 12 by 12-ft. Portland machine, residue on belt-conveyor to dump. An extraction of 90% is expected at a cost of \$1.75 per ton.

STOREY COUNTY

A cyanide plant for the treatment of concentrate saved in the Jacket mill, is to be erected within 90 days. It will save freight and smelter charges on this product, and increase the milling capacity of the present 200-ton plant by about 20%. Walter Techow will have control of the construction and operation.

WHITE PINE COUNTY

According to the *Ely Record*, the Newark valley, in the extreme western portion of the county, is fairly prosperous. It lies at an altitude of 6000 ft. The Ruby district has promising copper deposits.

OREGON

JOSEPHINE COUNTY

(Special Correspondence.)—The Rogue River Public Service Corporation is erecting dams and power-plants on the Rogue river near Grant's Pass, to compete with the Oregon-California company, whose plant is at Raygold above Gold Hill. The Ament dam and works have been secured for a central station, and will develop 5000 hp. G. E. Sanders is manager of the concern. A large hydraulic plant is being installed by the Althouse Mining Co. near the old town of Holland.

Grant's Pass, April 8.

LINCOLN COUNTY

(Special Correspondence.)—Gold is being recovered from the beach sands at Newport, near Yaquina bay, one of Oregon's popular summer resorts. Machines worked during the winter were reported to have saved from \$20 to \$60 per day, while single operators claimed from \$5 to \$10 per day. The gold is light and some mechanical device will be necessary to make good recoveries. The Oregon Bureau of Mines and Geology

will investigate the sands. This county is not a gold producer, and interest is being taken in the discovery.

Newport, April 6.

TEXAS

BRAZORIA COUNTY

(Special Correspondence.)—The first shipload of Texas sulphur shipped through this port from the Freeport Sulphur Co.'s mines left on April 8, on the steamer *Honduras*. It was also the first heavy tonnage of outbound cargo that has left the mouth of the Brazos river for nearly twenty years. The quantity of sulphur loaded was approximately 2100 tons, and the new conveyor handled nearly 60 tons per hour.

Freeport, April 10.

EL PASO COUNTY

Two 55-hp. direct-current back-gear motors for operating Stillwell-Pierce converters are to be installed by the El Paso Smelting Company.

UTAH

GRAND COUNTY

Prices offered last week by a uranium ore buyer are as follows, according to the *Greenriver Dispatch*: 2%, \$2.12; 2½%, \$2.25; 3%, \$2.50; 4%, \$2.60; 5%, \$2.70; 6%, \$2.85; 10%, \$3; 15%, \$3.25; and 20%, \$3.50 per pound. Sampling charge is paid for by buyer, analysis by seller. Above prices f.o.b. car lots Greenriver. The United States claims are being developed by E. V. Grant. The Radium Co. of America has shipped 100 tons of ore to date.

SUMMIT COUNTY

The Snake Creek tunnel is being advanced 10 ft. per day. In a raise from 1200 ft. in the Daly-Judge mine, a shoot of ore assaying 30% lead, 3% copper, and 60 oz. silver has been cut.

WASHINGTON

The itinerary of Bureau of Mines rescue car No. 5 is as follows: April 20 to 25, at United Copper and Copper King mines, Chewelah; April 27 to May 9, at Republic and Knob Hill mines, Republic; and May 11 to 15, at the state college at Pullman.

FERRY COUNTY

(Special Correspondence.)—Ore shipments from Republic during February totaled 3259 tons. This went to the Granby, Greenwood, Trail, and Tacoma smelters. The Ben Hur mine is producing for the mill and smelters about 100 tons of ore per day. The Trail plant generally gets it, but the Greenwood plant requires 2000 tons. Work in the mine is being done at 300, 400, and 600 ft. The ore averages from \$8 to \$15 per ton. Fifty-seven men are employed. Two men are sampling the Republic Mines Corporation property for Robert Sterling, who has another three weeks in which to exercise his option. At 300 ft. in the San Poil mine, a 4½-ft. ore-shoot, worth from \$11 to \$18 per ton, has been opened. C. C. Arrasmith has a lease on the Morning Glory mine, which is yielding ore worth from \$25 to \$124 per ton. The San Poil Consolidated Co. has decided not to sell its mine and plant.

Republic, April 22.

SILVER COUNTY

Besides the Copper King and United Copper mines at Chewelah, the Keystone and Joe Dandy claims are also being prospected. These have adits driven 600 and 350 ft., respectively. Spokane people are interested. The Copper Queen mine, near the Copper King and United Copper, has been optioned for \$100,000 to a Duluth-Superior syndicate.

WYOMING

CROOK COUNTY

The Bear Lodge gold mining district is described in a recent issue of *The Crook County Monitor*, from which the following is abstracted: The area is from five to eight miles north of Sundance, covering about 15 square miles, at an

altitude of between 4500 and 7000 ft. The Bear Lodge Gold Mining Co. has two groups of claims. The Last Chance has been prospected by an adit, incline shaft, vertical shaft, and other work. A large silicious lode containing iron, manganese, and gold was cut. Shafts from 25 to 400 ft. have opened the Daisy group. Additional machinery is to be installed. P. J. Scott is manager. The Warren Peak Mines Co. has driven an adit 285 ft., opening 1 to 6 in. of ore, giving very high assays. Eighteen inches of telluride ore occurs in this vein, and is worth up to \$16 per ton. The adit also cut a 5-ft. formation worth \$5 to \$7 per ton. A Gates crusher, 5-stamp mill, copper plates, cyanide plant, and power-plant are about completed. E. A. Bock is manager. A good deal of fair-grade ore has been developed in the Reuter Mining Co.'s claims. In 1913 about 1000 tons was treated in the plant containing a Gates crusher, Huntington mill, and cyanide plant. J. E. Reuter is manager. The Hutchins Consolidated Gold Mining Co. has spent about \$15,000 in prospecting and plant, and results are encouraging. J. D. Russel is manager. The Silver Top Mining Co. owns 200 acres near the Bear Lodge claims. Seventeen feet of ore has been cut, and recent work in another shoot is promising. Other workings give gold and silver from \$2 to \$7.20 per ton. A steam hoist, air-compressor, and two machine-drills are working. George H. Leeman is manager. A 175-ft. adit in the Pistol claims has given favorable results. The Beaver Creek Mining Co., with Tom Whitman as manager, has recently been formed. An adit is now being driven. Some copper ore was opened on the surface. Considerable work has been done by the Retriever Mining Co., and a fair tonnage of profitable ore is being opened. A steam plant is to be installed. At the Camp Bird a shaft is being sunk. Harry Williams is in charge. The Grizzly Bear Mining & Milling Co. has 23 claims. Adits are being driven to cut veins which assay 60c. to \$8.70 per ton at the outcrop. J. B. Richardson is president. Good copper ore is being opened in the Copper Prince, the oldest mine in the district. Sundance, the county seat, is well situated for a mining centre.

CANADA

BRITISH COLUMBIA

Rosland mines continue to ship heavily to the Trail smelter. The tonnage for the first two weeks during April and the total tonnage for the year to April 14 is as follows: Center Star, two weeks 7475, year 48,566; Le Roi, two weeks 2120, year 18,857; and Josie, two weeks 477, year 5146 tons. All the mines lost one day owing to the break at the West Kootenai Power Co.'s plant at Bonnington Falls. A contract, at \$13.50 per ton, has been let by L. Johnson, manager of the Union mine, 49 miles up the north fork of the Kettle river, to haul 1000 tons of ore to Grand Forks. A fair amount of work was done in the winter at this mine. One 500-ton shipment averaged \$49 per ton. The Standard Silver-Lead Mining Co., a Spokane concern, will pay an extra dividend of \$50,000 in May. On April 1 there was \$320,000 in the treasury. Up to April 21, the Granby company's Grand Forks smelter has treated 371,072 tons of ore for the current year, and shipped 6,340,550 lb. of blister copper. On May 13, a meeting of stockholders of the Company will be held in New York to discuss the proposed loan of \$3,000,000.

ONTARIO

According to A. A. Cole, in a report to the T. & N. O. commission, 16 Cobalt mills treated 664,845 tons of ore in 1913, against 455,517 in 1912, 381,871 in 1911, 305,513 in 1910, 126,421 in 1909, and 49,124 in 1908, a total of 1,984,749 tons. During the four weeks ended March 25 the Hollinger mine produced 11,820 tons of ore (541 tons from the Aeneas mine) averaging \$13.30 per ton. The recovery was 96.4% at a cost of \$4.33 per ton. The gross profit was \$121,641, and net surplus is \$753,447. Development continues satisfactory. On the 200 ft. level a shoot 6 ft. wide, worth \$12 per ton, was opened.

Personal

JOSEPH CLENDENIN is in Europe.
L. D. RICKETTS is in New York.
J. D. HUBBARD has returned to Chicago.
R. B. MOORE was up from Trona last week.
H. M. WILSON was in San Francisco this week.
A. E. DRUCKER was in Paris the middle of April.
R. E. CRANSTON is in Montana on professional business.
J. E. FLORANCE has gone to Guatemala on professional work.
CHARLES M. ROLKER has removed his office to 59a, London Wall, E.C., London.
E. P. MATHEWSON was in New York last week and has returned to Anaconda.
P. D. BURTT is in El Dorado county, California, at the Oro Fino and Crusader mines.
W. J. PITCHFORD, who has been visiting California, has gone to Washington temporarily.
SIDNEY J. KIDDER was married April 29 to Miss MARGARET POWELL at Marysville, California.
H. V. WINCHELL sailed for Europe from New York on April 16 and expects to return early in July.
F. L. HESS and J. A. HOLMES attended the dinner of the M. & M. Society in New York last week.
W. S. NORRIS has resigned as general superintendent for the Jumbo Extension M. Co. at Goldfield, Nevada.
D. C. JACKLING gave a dinner to a number of well known mining engineers on April 22, at the Engineers' Club, New York.
F. H. MORLEY left this week for Santa Barbara, planning to go later to Colorado Springs for the summer. While Mr. Morley is far from being an invalid, the doctor has forbidden regular work for him for the present, and he has, therefore, given up the position on the staff of the *Mining and Scientific Press* that he had held since December. He will write for the *Press* hereafter as a special contributor.

Obituary

A. H. W. JOHNSON, who has been the president of the Pulsometer Steam Pump Co. of New York, died on March 16. The management of the Pulsometer company will hereafter be in the hands of William J. Berow, who has been associated with it for many years.
J. D. KENDALL, one of the old time mining men of Utah, died at Salt Lake City, last week. He was best known as superintendent at the Central Eureka mine in the days of its maximum production. He had been out of active practice for some years at the time of his death.
A. SYDNEY ADDITON, who died at Berkeley, California, Wednesday of this week, was one of the well known metallurgists of the Pacific coast. Born in Massachusetts and educated in the East, his professional career was in the West. Mr. Additon was one of the pioneers in cyanidation work. In 1898 he was connected with the Toronto & Lillooet Gold Reefs, Ltd., at Lillooet, British Columbia, coming soon after to Berkeley, which was thereafter his home, except for two years passed as superintendent of the Mayflower Consolidated at Rhyolite, Nevada. While living in Berkeley he was for a time connected with the mining machinery business. Later he practised as a consulting metallurgist and in both capacities he designed and built many mills. From his experience in this work he wrote the series of incisive and interesting articles on 'Underestimating the Cost of Milling Plants' that we printed in 1913. In earlier years he had been a frequent contributor to the *Press*, and at all times he was generous in his exchange of information with fellow engineers.

Schools and Societies

McGILL UNIVERSITY, Montreal, senior students, under J. Bonsall Porter, will hold a mining school in the Kootenai and Boundary districts of British Columbia during the current month.
TWENTY-FIVE students from the mining and geological departments of the Lehigh University spent April 17 and 18 at Franklin Furnace, New Jersey. The program included a visit to the mine and mill, as well as a study of the geology and minerals of the region.

New York Metal Market Review

The exportation of copper assumed a normal basis in April; neither foreign nor domestic buying was heavy and prices declined steadily. Makers of brass and copper tubes reduced their prices 3c. per pound, in part because of foreign competition. The New York price of lead stood for weeks at the low level of 3.80c., a figure which was attractive to outside speculators and at which a big business was done. Spelter declined, without recovery up to April 23, because of the slower demand from the galvanized sheet mills. Tin lost over 2½c. in April, London declined heavily, and big business was absent. Antimony was featureless except for its low prices. Aluminum prices are practically unchanged. The feeling of most business men in the East is that should the conflict with Mexico be a thorough one, it will benefit business, at least for a time. Their choice is for a vigorous campaign, or none at all.

COPPER

April brought a cessation of the extraordinary run of copper exports which in March reached the record-breaking total of 45,793 tons. Authorities abroad have decried the suggestion that the metal arriving from America was going into so-called 'hidden stocks.' Henry R. Merton & Co., Ltd., London, for instance, says under date of April 4, after pointing out that the total visible European supply on March 31 was 26,129 tons, against 26,755 tons on March 14:

"What has hitherto been a matter of curiosity and speculation, and even suspicion in connection with these enormous supplies is gradually becoming a very clear and simple proposition, for upon the most searching investigation it must be admitted beyond doubt that practically every ton of copper recently imported into European ports has gone directly into consumers' hands, and the conjecture of hidden storings may be dismissed entirely. How much of these large quantities is required for immediate consumption and how much is used in order to fill the depleted reserves of manufacturers it is impossible to ascertain, but when it is remembered that the European stocks have now shrunk to barely 20,000 tons, it will be easily understood that the users of refined copper on this side of the Atlantic cannot any longer work with safety unless they build up a reserve supply at their own works."

It further is pointed out that European consumers would be in a dire way, should American demand suddenly awaken. Near the end of March, selling agencies were asking 14.37½c. cash, New York, for electrolytic, then quotations were advanced, first to 14.50c. cash, at which level a good business was done, and then, on April 3, to 14.62½c. cash, New York, or 14.75c., 30 days, delivered. This latter figure was the ostensible quotation of the leading sellers throughout most of the month, but resale lots were sold or offered below this level at all times. The advances were made on the strength of the huge exports in March. It developed early in April that consumers were comfortably supplied for their needs of that month and in part for May; but despite this, and the fact that consumers were inclined to await the appearance of the March statement of the Copper Producers' Association, the advance to 14.75c. was made. The statement, which appeared on March 8, showed that the marketable copper on hand April 1 was 64,609,319 lb., a decrease of 13,762,533 lb. as compared with March 1, but the figures had no radical effect on the market. Concessions in price became heavier as the month progressed, about 14.55c. cash being the market April 8, while in the following week there were several reductions, until on April 15, 14.37½c. could be done. This price held for a few days, but by April 22, the metal could be had at 14.25c. cash, and the next day as low as 14.12½c. was quoted. With the decline in buying abroad came easier prices there, but even before this there were evidences that the domestic market was too heavy which resulted in the concessions referred to. The

lots offered were small, but many, and in the aggregate more copper was to be had than demand called for. Trade in brass and copper products felt a slightly better demand in the first week of the month, but it soon diminished and the advances to 14.50c. cash and 14.62½c. cash were considered as examples of trying to boost the market too rapidly. Eastern mills rolling copper complained that the orders they were getting did not assure activity more than a few days ahead. The third week of the month was dull, with the range of quotations wide. An interesting disclosure at this time was that American makers of brass and copper tubes have been compelled to reduce their base prices 3c. per pound to meet competition, most of which came from abroad. The new quotations were 16c. for seamless brass tubes and brass tubes, iron pipe sizes, and 19½c. for copper tubes. Ordinary brands of Lake copper were quoted at 14.75 to 14.87½c. cash, in the early part of April, but prices tapered off as the month progressed, although choice brands remained nominal at around 15c. cash. Exports, up to April 24, were 23,388 tons. The Waterbury average for March was 15 cents.

LEAD

The report for March left the New York price of lead at 3.90c., but on March 30, the big interest reduced its New York quotation to 3.80c., New York, whereupon the St. Louis quotations came down to 3.67½c. The Western price varied between the latter figure and 3.70 throughout April, while the New York price was unchanged. The reduction to 3.90c. induced good buying of small lots and that to 3.80c. brought about some real heavy purchasing. With the low prices came an easier market abroad and the exportations which had been a feature theretofore were lessened. At the lower prices the market looked attractive to investors in no way regularly associated with dealing in lead, who bought to some extent for speculation. Following the starting of low prices and the big sales, there was not much doing until the latter part of the month, when there was again fair buying on a basis of 3.67½c., St. Louis, which caused the Western price to advance to 3.70c. again. Firmness prevailed toward the end of the month.

TIN

This metal lost over 2½c. per pound in April, the almost steady course of the market being downward. The price on April 1 was 37.75c., on April 8, 36.75c., on April 15, 36.15c., and on April 23, 35.12½c., for large lots, prompt delivery. London declined steadily also, and at times, in the third week of the month, there were drops of £2 to £3 in a single day. The London quotation for spot on April 22, £161, was the lowest of the year. Consumers did not come forward to any great extent at any time up to April 22, despite the fact that prices were low and sellers pressing to get business. The best of the buying was on the part of dealers. The unsatisfactory state of the American iron and steel trade was held responsible for a large part of the dullness and corresponding weakness. It was hoped that orders might accumulate over the Good Friday and Easter holidays, which were observed by the Exchange here and abroad, but more particularly on the other side, where the London Metal Exchange closed from the eve of Good Friday until the following Tuesday. But the looked for orders were wanting. Deliveries into consumption in March were good, amounting to 4450 tons. The total for three months of 1914 showed a decrease of 1750 tons as compared with the same period last year. The total visible (world's) supply on March 31 was 16,989 tons, or 5857 above that of March 31, 1913. In stock and landing April 1 was 1997 tons. The arrivals in April up to the 23rd amounted to 4326 tons and there was afloat on that day 1160 tons. On April 24 tin broke £5 5s. at London, and the New York price fell about 1c., which made the total loss of the month about 3½c. Later in the day there was a recovery which left a net loss of £4.

The Metal Markets

LOCAL METAL PRICES

San Francisco is not a primary market for the common metals except quicksilver. The prices quoted below therefore represent sales of small lots and are not such as an ore producer could expect to realize. Ore contracts usually call for settlement on the basis of Eastern prices, less freight and treatment charges. The prices quoted are in cents per pound, except in the case of quicksilver, which is quoted in dollars per flask of 75 pounds.

San Francisco, April 30.

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, April 30.—Copper had a downward tendency at the beginning of the week, but is moving up, and is now strong, European and American consumers buying. Copper shares show little change, but the demand for them is increasing. Amalgamated is firm, and A. S. & R. dropped slightly. Lead is firm. The St. Louis market is dull at 3.80c. for lead, and 4.90c. for spelter. This metal is quiet in New York. Quotations in London are copper, £64 2s.6d.; lead, £19; and spelter, £21 7s.6d. per ton. Bar silver is 27.18d. per ounce.

SILVER

Below are given the average New York quotations in cents per ounce, of fine silver.

China and India have both been buying, as well as the Continent. Orders from India have been mostly for shipment by the steamer which is timed to arrive in Bombay for the May settlement, according to Samuel Montagu & Co. The total silver imported into the United Kingdom up to the end of March was 22,449,046 oz., compared with 33,634,311 and 34,474,199 oz. during similar periods in 1913 and 1912. The reduction of supplies to less than two-thirds of those in the previous years, chiefly as a consequence of the difficulties in Mexico, demonstrates what a powerful factor that country is in the silver market. In gauging the present position of the market, some importance should be attached to the change of sentiment which must follow the final dispersal of the erstwhile speculative stocks. The knowledge that these existed, the uneasiness created by their size, and the possibility of their forcible realization, has, during recent years, discouraged buyers for trade purposes—who, be it remembered, are the principal consumers of the metal—from replenishing their stocks. The rise in price which attended the Indian Government purchases, failed to inspire confidence, as the market was well aware that speculative stocks had been only partly reduced. It is probable that, in these circumstances, trade consumers all over the world have been working from hand to mouth during the last three years or more. Toward the close of this period, the financial crisis of last December, in India, rendered up-country buyers unable, as well as unwilling, to send buying orders. It is, therefore, likely that a state of silver semi-starvation obtained in the country bazaars, pending an improvement in the financial situation. Buyers were well aware that 25,000,000 oz. could be obtained from the Syndicate at any reasonable price. All this tended to produce an inert and featureless market. With the exhaustion of the Syndicate's stock, the situation has changed.

COPPER

Quotations on copper as published in this column represent average wholesale transactions on the New York market and

refer to electrolytic copper. Lake copper commands normally 1-5 to 1-4c. per lb. more. Prices are in cents per pound.

The copper situation in England and Europe at the end of March was as follows, according to Henry R. Merton & Co.: stocks of standard and fine metal at London, Liverpool, Swansea, Newcastle, and Birmingham, 9948; fine copper at Havre, 1791; fine at Rotterdam, Hamburg, and Bremen, 19,979; and afloat from Chile to Europe, 2350; from Australia, 3800; a total visible supply of 26,129 tons, or 58,528,960 lb. At other European ports there was estimated to be 600 tons. The respective figures at the same date of 1913 were as follows: 22,527, 3534, 38,874, 2200, 4000, 45,074, and 2500 tons.

LEAD

Lead is quoted in cents per pound or dollars per hundred pounds, New York delivery.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

TIN.

New York prices control in the American market for tin, since the metal is almost entirely imported. San Francisco quotations average about 5c. per lb. higher. Below are given average monthly New York quotations, in cents per pound:

| Asphaltum | | | \$5.50 to 12.50 |

Company Reports

BRACKPAN MINES COMPANY

This is one of the important Rand companies, and the report for 1913 includes the following: Work was hindered by a subsidence of some stopes and scarcity of labor, consequently development went behind, affecting the grade of ore by 70c. per ton. Ore reserves total 2,242,000 tons averaging \$6.70 per ton, a reduction of 215,000 tons. Ore mined was 695,173, and including that on the surface the total was 713,263 tons. Sorting reduced this to 611,519 tons, or 14.265%, while 613,269 tons was milled averaging \$6.83 per ton. The recovery was \$6.70 per ton, with a total value of \$4,150,000. Costs were \$4.51 per ton. The net profit was \$1,400,000, and \$1,150,000 was paid in dividends. The sum of \$290,000 was carried forward.

NEW IDRIA QUICKSILVER MINING COMPANY

This Company operates in San Benito county, California, and the report covers the past year. The general manager, W. K. Buckminster, states that development totaled 9182 ft. The upper levels have been worked extensively, and are nearly depleted to 'D space' at No. 4 level. Above No. 4 $\frac{1}{2}$ level, 'E space,' two new stopes show a fair tonnage of ore. A downward extension is expected. Above No. 6 level prospecting will be carried on extensively, and may produce a good deal of ore. Probably areas above No. 7 level will give some ore, also above No. 8 level. A small body of high-grade ore is opened at the west end of No. 9 level. The Molino adit has been in heavy ground, but is being pushed ahead to get under the San Carlos deposits. Three furnaces were in commission. No. 1 will be repaired in the spring. The price of quicksilver was low during the year. Ore produced was 76,993 tons, yielding 9700 flasks of quicksilver. The revenue was \$363,954; net earnings, \$65,013; dividends, \$40,000; and total surplus, \$144,600.

ARIZONA COMMERCIAL MINING COMPANY

This Company operates at Copperhill, near Globe, Arizona, and the report is for 1913. Development showed the following results: On No. 5 level there is 120 ft. of 2% copper ore over a width of 2 ft. There is no way of handling this grade at present. On No. 7, and between it and No. 6 level, there is 200 ft. of ore, including several lenses of high-grade ore. About 80 ft. averages 4.5% copper over 4 ft. At No. 10 there is a shoot 25 ft. wide, of smelting ore, averaging 2% copper, 40% iron, and 20% sulphur. On No. 12 the vein has been proved by driving a drift in the foot-wall and cross-cutting at intervals of 100 ft., exposing from 46 to 100 ft. of ore of various grades, including several streaks of smelting ore. Shipments from development were 494 tons averaging 3.58% copper. A watercourse was cut on No. 12 level in October, and a dam was built in the main cross-cut and work abandoned on the level. The shaft was sunk about to No. 14 level at the end of the year. A triplex pump was installed, and a change-house for 100 men erected. Generally, the work being done is thoroughly proving the property.

Decisions Relating to Mining

ANNUAL LABOR IN ALASKA—FORFEITURE FOR NON-COMPLIANCE

Under the laws of Alaska, when a mining location has lapsed owing to the non-performance of annual labor during a given year, there can be no saving of the locator's rights by resumption of work prior to the intervention of other parties. The location is absolutely forfeited by operation of law at the expiration of the year in which no assessment work is done.

Ebner Gold Mining Co. v. Alaska-Juneau Gold Mining Co. (Alaska), 210 Federal, 599. January 5, 1914.

OIL LEASE—FORFEITURE UPHOLD

Where lessees under an oil lease, in violation of the express terms of the lease, abandoned a drilled well and ceased work for a greater period than 60 days thereon, the lessors are clearly entitled to claim a forfeiture without waiting for the expiration of the term. Nor is it necessary for the lessor, in order to show compliance on his part with another provision of the lease requiring him to pay one-half the cost of drilling a second well, to make a tender of such one-half before work on the second well is begun.

Dittman v. Keller (Indiana), 104 Northeastern, 40. February 3, 1914.

OIL LEASE—EFFECT OF DUE DILIGENCE

The rule for construction of covenants in an oil lease most strongly in favor of the lessor cannot be invoked by him to dispossess a lessee who has faithfully performed all his covenants, has discovered oil in paying quantities, and paid the stipulated royalty. It will be presumed that an oil lease is made for immediate development, unless the contrary appears from its language. Upon the discovery of oil and gas in paying quantities, the lessee acquires a vested interest in the oil and gas as long as it can be produced in paying quantities, and the subsequent abandonment of several wells because the oil may be more profitably mined through a fewer number of wells does not warrant a forfeiture of the lease.

Burgen v. South Penn. Oil Co. (Pennsylvania), 89 Atlantic, 821. January 5, 1914.

MINERAL ENTRY—GROUNDS FOR CANCELLATION

Land embraced in a subsisting patent issued upon a timber and stone entry is not subject to location and entry under the mining laws, notwithstanding the land was embraced in a valid subsisting mining location at the date of the timber and stone entry and was at that date known to be chiefly valuable for mineral. Where the discovery upon which the location was based lies within the boundaries of the prior timber and stone patent it is lost to the mineral applicant and such loss invalidates his location unless, prior to application for patent or the asserting of an adverse claim to the ground under the mining laws, he makes a sufficient discovery within the remainder thereof. The verification of an application for patent by an attorney-in-fact for the claimant at a time when the claimant himself is both resident and physically within the land district, is contrary to regulations, and invalidates an entry allowed upon such application. Forfeiture of a co-owner's interest under Section 2324 Revised Statutes cannot take place where claimant has obtained possession under color of a laborer's lien, but has never foreclosed the same in accordance with the state law. He is not a co-tenant with the former owner within the meaning of said section.

F. E. Robbins (Land Department) 42 Land Decisions, 481. September 3, 1913.

Book Reviews

THE MINING WORLD INDEX. For the second half of 1913. By George E. Sisley. Volume IV. P. 190, also 28 pages of authors' index and subject index. Mining World Co., Chicago, 1914. For sale by the *Mining and Scientific Press*. Price \$2.

The regular publication of this index is creating more interest each half-year, especially when it is known that the articles from about 330 journals and society transactions throughout the world are noted. These include papers of interest to mining men, metallurgists, and engineers. References to each metal and non-metal, mills and treatment of ores, chemistry and metallurgy, are in separate chapters, themselves properly indexed, so that any subject is easily found. The addition of an authors' index makes this material even more readily available. The volume is of handy size, and is well worthy of being placed in any library.

ROCK EXCAVATING AND BLASTING. By J. J. Cosgrove. P. 179. Ill., index. The National Fire Proofing Co., Pittsburgh, 1913. For sale by the *Mining and Scientific Press*. Price \$2.50.

This work was written for the purpose of aiding the young engineer, superintendent, rockman, and miner, that he might have a more thorough knowledge of explosives, how to handle them and to get the best results in the various kinds of rock excavating. For those who are in charge of rock excavations, either open-cut, tunnel work, or shaft-sinking, this book will be found of particular interest. The work is fully illustrated, showing how to drill bore-holes to get the best results; how to charge the holes, methods of tunnel driving, shaft-sinking, quarry work, and open-cut excavating. The subject of rock-drilling tools, machinery, and explosives is also discussed.

THE MECHANICAL ENGINEER'S REFERENCE BOOK. By Henry Harrison Suplee. J. B. Lippincott Co., Philadelphia. P. 919. Index. For sale by the *Mining and Scientific Press*. Price \$5.

This is the fourth edition of Mr. Suplee's well known work, the first having been published in 1903. An appendix has been added giving data on miscellaneous matter, including the characteristics and application of aluminum; various metal alloys; a depreciation table; general data on coal; collapsing and bursting strength of pipe; heat transmission; notes on friction and lubrication; table for the determination of speed in railway trains; train resistance; mine ventilation; tables of slopes; foundation data and masonry construction; roof construction; coefficients of friction; general data on power-transmission machinery; floor construction; reinforced concrete columns, and entropy.

DESIGNING AND DETAIL OF SIMPLE STEEL STRUCTURES. By Clyde T. Morris. McGraw-Hill Book Co., New York. P. 249. Index. For sale by *Mining and Scientific Press*. Price, \$2.25.

This is the third edition of Mr. Morris' well known work, the first having been published in 1909. The entire book has been revised and several of the chapters have been partly rewritten. A new chapter on highway bridges has been added, together with a reprint of the specifications for steel highway bridges of the State Department of Ohio. The text has been prepared primarily with a view to the presentation of data applicable to simple structures and which can be taken up in the technical schools during the comparatively limited time usually allotted to the subject. General cases and specific examples are given of the application of the laws of statics to steel structures in order that details may be produced which are in accordance with the stresses to which they are subjected.

Industrial Progress

Oxy-Acetylene Welding and Cutting

One who has seen an oxy-acetylene apparatus at work cannot but be impressed with the advance which this comparatively simple apparatus marks in the field of cutting and welding. Its uses are many and it has been found an especially valuable adjunct to the mine machine-shop. Among its many uses may be mentioned the reclaiming of cracked or broken castings of cast iron, steel, brass, bronze, or aluminum; adding metal to parts subjected to friction; repair-

PORTABLE WELDING OUTFIT.

ing boilers by welding in new parts or filling in cracks edge to edge; welding split piping, which can be done usually without breaking the connections; welding flanges or pipes; cutting off rivet heads and driving out the shanks; putting extensions on shafting; restoring to original size bolt holes which have been worn by use; adding small metal parts which have been broken off or are missing; recovering teeth broken from gear wheels; cutting steel or wrought iron down to the thickness of one-eighth inch; cutting steel plates, girders, rails, and all kinds of structural steel; making metal containers without joints; removing defective parts and repairing shapes with perfect sheets of the same shape welded into position edge to edge; and many similar uses.

The accompanying halftone shows a portable outfit manufactured by the Great Western Cutting & Welding Co. of San Francisco. This is particularly suited for shops and mine use when the work is in different places, the outfit

being easily moved from place to place, and it is always ready for use. By changing the torch the apparatus may be used for either cutting or welding. The torches used are made under German patents, but have been improved under American patents. The generator, regulators, and controlling devices are based upon years of experience in both this country and Europe.

The Silver King Underground Station

In *Mine and Quarry* for April, H. E. Moon describes, as follows, the underground air-compressor and hoist station now being completed in the Silver Hill section of the property of the Silver King Coalition Mines Co., Park City, Utah.

It became advisable here to sink a shaft from 1200 to 1300 ft. deep at a point about two miles in from the mouth of the Alliance tunnel. This point is under 1600 ft. of cover and corresponds in elevation with the 500-ft. level of the main King shaft, through which the principal operations have been carried on thus far. The proposed shaft will be cut through to the quartzite contact, underlying the orebody that is now being worked, through the King shaft, a depth of 1300 ft. The Company decided to construct an underground station in the solid rock. This station is probably the largest one of the kind in this country. There are three rooms or chambers; first, a compressor room, 42 ft. long, 30 ft. wide, and 20 ft. high. The roof arch of this room is elliptical, and all the walls, as well as the roof, are of heavy reinforced concrete, designed to support the heavy top of badly broken limerock. Adjoining the compressor room is, second, the engine-room, 42 ft. long, 35 ft. wide, and rising in height from 12½ ft. at the back toward the shaft, at which it is 24 ft. high. These rooms are finished with smooth white cement plaster and are well lighted by electricity.

A first-motion, double-reel hoisting engine has been installed, driven direct by a 200-hp. motor, running at 65 r.p.m. and taking direct current at 600 volts from a motor-generator set placed in the compressor room. Air for the tunnel, shaft, and construction of the station has been supplied by three large air-compressors on the surface, which also furnish air for the King shaft and its workings. It was considered advisable to install an auxiliary compressor in the underground power station, to act as a booster on the main line, and ultimately to give regular additional capacity for sinking the shaft and developing the new workings below the tunnel-level. The machine selected for this purpose, particularly on account of its compactness and high air capacity per unit of floor space, was a Sullivan class WJ-3 angle compound compressor, with low-pressure cylinder 18 in. diameter, high-pressure cylinder 11 in. diameter, and a common stroke of 14 in. At its rated speed of 215 r.p.m., this machine has a displacement capacity of 886 cu. ft. of free air per minute.

The idea of the engineers in designing this plant was to have the compressor utilize the electric current during the intervals when the hoist was not running, thus eliminating excessive peak loads. To accomplish this, the compressor unloader is connected with the hoist, so that when current is thrown into the motor of the latter, this action automatically unloads the compressor and allows nearly the entire power of the synchronous motor set to be available for the hoist motor. When the hoisting current is thrown off, the unloader on the compressor is automatically opened, allowing the machine to work under full load again, thus providing a high load factor for the motor-generator set, as well as a nearly constant current demand. This synchronous motor-generator set furnishes direct current at 600 volts for the hoist, and the motor of the set takes current from the transmission lines on the surface at 2200 volts A.C., with a rated continuous input of 250 kva., and having 80% power factor. A motor-generator exciter set furnishes direct-current excitation for the large synchronous motor of the large set.

EDITORIAL

CURIOUS metal is the name applied to recent discoveries in El Dorado county. The characteristics of this 'curious metal' are described as "sharing the properties of both platinum and tungsten"; "so heavy that a chunk of it can scarcely be lifted in the hand"; "gives off emanations called the true electro rays which have the property of electro-plating"; and last, but not least, "will gold-plate an old tin can." While the fountain of youth has not as yet been linked with this discovery, hopes are entertained in that direction.

VALUING placer ground is a specialty, and many points that are so clear to a specialist as to seem not worth mentioning are continually confusing laymen. Early this year, both in London and New York, a great deal was made of the fact that the Pato dredge returns were over-running the reported average for the ground. We pointed out, January 24, that the fact was of little significance, and are glad to print this week a brief article by Mr. L. A. Decoto explaining exactly how such an over-run might occur in a theoretical case. Mr. Decoto's note has all the more value because he was himself in charge at Pato for some time. In fact, the Oroville officers, properly enough, began work on the richest ground, so as to recover as promptly as possible the money invested.

SPEAKING of intervention, we note with approval that it has been begun in Colorado. It is not necessary to decide the merits of the question in controversy between miners and operators to warrant one in affirming that the state has failed miserably to maintain the peace, and that is the first duty of a civilized government. Killing men, women, and children, destroying mines, using machine guns and armored trains, is war whether it be in Colorado or Mexico, and state troops that cannot or do not preserve the peace at home are of doubtful value as volunteers for foreign service. If there is doubt as to the constitutional right of the United States to intervene in Colorado, how much clearer is the right as to Mexico? California, in insisting on anti-alien legislation, was considered somewhat regardless of the light in which it placed the United States abroad, but is not the same thing to be said of Colorado, which persists in a merry little civil war all its own at the very time that United States forces are being used to restore order in a neighboring republic?

ALASKA coal from the Matanuska fields, which was mined last summer under the direction of Mr. George Evans, acting for the Bureau of Mines, was recently delivered at tide water. The coal was freighted by an expedition headed by Mr. Jack Dalton, who estimates the cost of the coal delivered at tide water at \$65,000, or about \$72 per ton. While it would seem that this was a rather expensive undertaking, it is really the cost of getting a sample, not of mining coal. The work marks an important step in the development of the Alaska fields, and a correct knowledge of this fuel will undoubtedly lead to much needed development.

DECISION of the case on appeal of Minerals Separation, Limited, *versus* James M. Hyde, was announced Monday last in this city. We present the complete text on the following pages and therefore little comment is necessary. Our readers will, we hope, pardon the necessity for offering them the matter in small type rather than our customary 10-point. This is a case where we feel that prompt publication in full is more important than form, for the decision is of the greatest importance to all concerned in metallurgy. As forecasted in our editorial of April 18, the court decided the case virtually upon the technical question whether or not "the 'agitation froth' of the Minerals Separation process is different from the oily 'magma' of the Froment or the areated oily mass of the Kirby and similar processes." Having found that as a matter of fact it was not different, the secondary question of extent of use did not come into play, as it might have done had the court been in doubt on the main point. The decision is a sweeping one, and, in brief, Minerals Separation is denied a basic process patent on the ground of no invention. It is a hard blow to that enterprising and able concern, for while, as we have been careful to point out, such a decision as has been rendered in this case is not, in the United States, absolutely final, the principle enunciated is very likely to control in any future litigation. Minerals Separation owns many patents and there is room for conflict over apparatus patents alone, but to sustain any claim to a basic process patent will be difficult. The Company has made no announcement yet of the policy it will pursue under the new conditions. To Mr. James M. Hyde and the Butte & Superior company hearty congratulations are in order. They were clear sighted enough to see, what the court has now held, that using the knowledge of the prior art and the skill of a careful metallurgist, it was possible to make a satisfactory recovery by flotation without infringing on Minerals Separation. What they can do others can do, and the process, as a process, is open to all; assuming that the principle announced be followed in any subsequent litigation. We wish it were possible to announce that there would be no more lawsuits, but apparently it is the way of the world in mining and metallurgy as well as in general industry.

Korean Gold Mines

The gold mining concessions in Korea are the subject of an article that we print this week by Mr. A. E. Drucker. His account is most interesting as a graphic portrayal of the trend of mining and milling in Korea and the scope and outlook of the industry. Since it was written, the re-grinding Taracol plant of the Oriental Consolidated Mining Company, mentioned as completed in May 1912, suspended operations, as recorded in the *Mining and Scientific Press* of March 14. This occurred on January 14 of the present year. The results were held to be not comparable with those of the old leaching plant, where work has been resumed.

Returns for 1913 at the Suan Concession now available show that the 40-stamp mill treated 71,535 tons and recovered gold to the value of \$671,536, with a profit of \$376,303. Dividends equal to 50 per cent of the capital stock were paid to the shareholders during the year. The Tul-Mi-Chung property on the Suan Concession is about to enter the producing stage, and a new 300-ton mill is soon to be erected which will be in operation within the next year. All of the machinery for the Company's new power plant at Pyeng Yang has arrived, and it is expected to have the plant in operation by September. This plant is 52 miles from the concession and consists of two 1000-kilowatt turbo-generator units. Other mines and prospects are in course of development on the Suan Concession and the outlook is most encouraging. Besides maintaining a 50 per cent dividend rate during the past three years, the ore reserves have increased from 421,300 tons valued at \$6,083,500 in 1912 to 633,340 tons valued at \$7,642,300 in 1913. The French concession has been hampered in the conduct of mining and development operations by internal friction in the conduct of the Company's affairs. That the property is of merit is beyond doubt and future exploitation is full of promise. The Chosen Gold Mines, Ltd., holding mining property at Kok Kang Kol, in south central Korea is also numbered among Korea's probable producers. A 40-ton mill has recently been put into operation with \$16 ore and a 93 per cent extraction, which the Company's engineers report after a great deal of experimental work. The future looks most encouraging. The Kapsan Mining concession is the last of the large concessions to be granted, and engineers' reports on development work to date variously estimate the reserves at from about 125,000 to 175,000 tons of ore which will average a little over 10 per cent copper.

With the decline in gold production in the older mining districts of the world, it is gratifying to note the rejuvenation of this ancient field in the Orient. While the present gold output of Korea, or Chosen, as the Japanese are wont to call the country, is not great, the mineral outlook is promising and important developments are anticipated. At a later date we shall publish a detailed account of the geology and ore deposits of one of the most interesting districts.

Decision in Flotation Litigation

The United States Circuit Court of Appeals for the Ninth Circuit, in the case of James M. Hyde, appellant, *v.* Minerals Separation, Limited, and Minerals Separation American Syndicate, Limited, appellees, argued at San Francisco in January, handed down the following opinion May 4.

The judges before whom the case was argued were Gilbert, Ross, and Dietrich, and the opinion was written by Mr. Justice Gilbert. The decision follows:

This is an appeal from the decree of the Court below sustaining Letters Patent No. 835,120, issued to Sulman, Picard, and Ballot, on November 6, 1906, and assigned to Minerals Separation, Ltd., and Minerals Separation American Syndicate, Ltd., adjudging the appellant herein to have infringed the same, and enjoining further infringement. The patent is for new and useful improvements in ore concentration. Its object is to separate metalliferous matter from gangue, by means of oils and fatty acids which have a preferential affinity for metalliferous matter. In the specifications reference is made to United States Letters Patent No. 777,273, granted to A. E. Cattermole. The Cattermole patent specifies that an amount of oil varying from 4% to 6% of the weight of metalliferous matter present is agitated with an ore pulp, so as to form granules which can be separated from the gangue. The specifications of the patent in suit state that the inventors have found that "if the proportion of oily substance be considerably reduced—say to a fraction of 1% on the ore—granulation ceases to take place, and after vigorous agitation there is a tendency for a part of the oil-coated metalliferous matter to rise to the surface of the pulp in the form of a froth or scum," and the specifications add: "The proportion of mineral which floats in the form of froth varies considerably with different ores, and with different oily substances, and before utilizing the facts above mentioned in the concentration of any particular ore, a simple preliminary test is necessary to determine which oily substance yields the proportion of froth or scum desired."

Patent Claims

There are 13 claims in the patent. The first is "the herein described process of concentrating ores, which consists in mixing the powdered ore with water, adding a small proportion of an oily liquid having a preferential affinity for metalliferous matter (amounting to a fraction of 1% on the ore), agitating the mixture until the oil-coated mineral matter forms into a froth, and separating the froth from the remainder by flotation. The next three claims specify the quantity of oil as amounting to "a fraction of 1% on the ore." The second claim adds to the first the use of slightly acidified water. The third adds to the second, "warming the mixture." The fourth adds to the third "and removing the oily coating from the mineral." The fifth specifies the oil as "oleic acid of a quantity of from 0.025 to 0.5% on the ore." The sixth adds to the fifth the use of water containing 1% of sulphuric acid. The seventh adds "warming the mixture to 30 to 40°C." The eighth specifies the use of oleic soap solution, to produce oleic acid, "amounting to 0.02 to 0.5%." The ninth is "the process of concentrating powdered ores which consists in separating the mineral from the gangue by coating the mineral with oil in water containing a small quantity of oil, agitating the mixture to form a froth, and separating the froth." The tenth adds to the ninth "warming the mixture," and the eleventh adds the use of acid. The twelfth adds "separating the froth from the remainder of the mixture," and the thirteenth adds a current of water to carry off the coarser minerals, and "filtering off the froth and removing the oleic acid therefrom by treatment with an alkali."

The answer of the appellant denied that Sulman, Picard, and Ballot were the first inventors of the process, or that there was any invention described in the patent, and denied infringement, and alleged that the process described in the patent was old and not patentable; that the process had been included in certain patents which were enumerated in the answer. The appellant was adjudged to have infringed claims numbered 1, 2, 3, 5, 6, 7, 9, 10, 11, and 12.

The appellees' process depends primarily upon the affinity of oil for the metalliferous portion of powdered ore when mixed with water. It is conceded that that affinity and the

fact that oil will carry the metalliferous portions to the surface of the mixture, while the rock or gangue will sink, have been known for many years. That which is presented as new in the patent, and as the pivotal discovery on which its validity depends, is the formation of a froth or scum containing the metalliferous matter produced by agitation of the pulverized ore in water, by the action of oil in a quantity less than 1% of the quantity of ore treated.

Early Patents

Turning to the patents which are adverted to as showing the prior art, we find the following: The British patent to Haynes, No. 488, issued in 1860, recommends the use of from 11 to 25% of oil by weight to the finely powdered ore, the mixture to be agitated with water, either warm or cold, until the earthy matter sinks and the metal is gathered by the oil. In that process the sunken earthy matter is removed, fresh ore is replaced, and the operation repeated with the same oil until it will take up no more metalliferous matter. The United States patent, No. 348,157, issued to Everson, in 1886, specified the use of oil in quantities varying from 5 to 18%. Miss Everson was the first to make the important discovery that the affinity of the oil for the metal was increased by the addition of an acid. In the description of her process, she states that in the operation, the mass is broken up and thoroughly stirred in water, in a vessel provided with a mechanical stirrer, and having an outlet or outlets at the bottom for the escape of the water and sand. The Schwartz United States patent No. 807,503, applied for in May 1904, and granted in December 1905, describes a process in which the dry ore is first mixed with enough oil to make a thick pasty mass, and water is thereafter added, and the mass is agitated so as to cause the metallic particles to float. The quantity of oil to be used is not further specified, but it is in the testimony that the Schwartz process has been experimentally used "with cotton seed oil, the quantity used being 3.6% of ore treated. The United States patent to Kirby, No. 809,050, was applied for December 14, 1903, and granted January 16, 1906. The oil used by Kirby was kerosene oil in which 5% of bitumen was dissolved. One of the claims is as follows: "The process of separating minerals, which consists in mixing together the pulverized mineral material, a considerable quantity of water and a solution of bitumen in a distillable hydrocarbon liquid, the proportion of bitumen in solution being substantially sufficient to insure the coating and entrainment of the mineral particles; and allowing the same to settle, and removing therefrom the floating layer of said solution and the mineral particles which have been coated thereby." In his specifications he says: "These materials to be so thoroughly agitated together as to finely subdivide said solution into small globules, and bring said globules into contact with substantially all of the pulverized mineral particles, which will by preference adhere to them." And in describing the means for the agitation, he specifies a "vertically rotating shaft" in the mixing tank, which it is said is to be "rotated rapidly." No specific quantity of oil is prescribed, but it is stated in the specifications that a sufficient amount of the kerosene and bitumen in solution is to be used, "excellent results being obtained by using one-fourth to three-fourths as much by weight as ore." In the Froment Italian patent, issued May 20, 1902, and the British patent to Froment, issued June 4, 1903, the invention described is declared to consist "of a modification of what is known as the oil process of ore concentration." The modification consisted in releasing gas from the finely powdered ore, and "adding a suitable oil," resulting in a flotation of the oil and metal to the surface. Froment mentions the use of gas to aid in the flotation of sulphides reduced to powder and moistened by a fatty substance, in explanation of which the patentee says that if, for example, in a test-tube there is placed 10 gm. of sulphurated copper ore, with its gangue, a gram of limestone, the whole reduced to powder, and there is added thereto 30 gm. of water, a few drops of sulphuric acid "and a thin layer of ordinary oil," and the mixture is agitated for a second, the whole of the copper pyrite will instantly rise to the top of the liquid. The patentees of the appellees' patent purchased from Froment on November 17, 1903, the Froment patent, and Froment agreed to send all possible information, together with the plans, drawings, and model plant, to England, for the use of the purchasers. This agreement was carried out in December 1903. The instructions which Froment sent contains the following: "If the ore contains more than 5% of metallic matter, such as copper, lead, it will be neces-

sary to use a little more oil. As a general rule one may assume 1% of oil for ore containing up to 5% of metals, 1½% of oil for ore containing up to 10%, and so on, up to ores containing 50% of metallic lead, which it was said would require 3½% of oil." In the instructions the mixing device is described as composed of a cylindrical body made of strong sheet iron, riveted with bolts, "in which two stirring devices work in opposite directions, making about 300 revolutions per minute." The Cattermole process, which is referred to in the Letters Patent in controversy in this suit, is presented in two British patents, one No. 777,273 and one No. 777,274, both of date December 13, 1904. The amount of oil specified in the Cattermole process is from 4 to 6% of the weight of metalliferous mineral matter present in the ore. This quantity with the average ores would be less than 1% of the mass treated. The fact that the final purpose of the Cattermole process is to increase the sinking tendency of the metalliferous mineral instead of removing it upon the surface, does not render that process any less instructive as to the state of the prior art, for there are two distinct steps in the treatment of the ore—there is first a violent agitation to cause the oil to gather up the metalliferous particles, as in the case of other oil flotation processes. Then follows a slow, smooth stirring of the mass, which releases the air from the froth or scum and causes the oil and metalliferous particles to adhere together and form granules of sufficient size and weight to sink, after which the mass at the bottom is drawn off, and the particles of sand and gangue therein are forced upward and thus separated from the granules of metal. Here is described a process in which the quantity of oil used approximates the quantity which is called for by the appellees' patent, a fraction of 1 per cent.

Comparison of Present and Past Patents

When the claims and the description of the process of the appellees' patent are compared with the patents of the prior art, it will be seen that the only material difference is in the smaller quantity of oil which the appellees use. Comparing the appellees' process with the Froment process, it will be seen that in both powdered ore is mixed with a sufficient water to form a freely flowing pulp; that while Froment recommends the use of oil of from 1 to 3½% of the ore by weight, the appellees recommend a fraction of 1% of oil; that Froment recommends the use of ordinary oil or a suitable oil, while the appellees' patent mentions oils, fatty acids, and oleic acid; that in both processes there is agitation of the mixture; that in both processes a small quantity of sulphuric acid is recommended; that in both processes the mixture of all the substances is made before the agitation; and that in both processes bubbles of air or gas are caught in the sulphides in the form of a froth which rises to the surface. So also in the Kirby patent, the various steps of the process are similarly described. We find there the pulverization of the ore, mixing it with water to form a flowing pulp, mixing therewith kerosene oil with a small percentage of bitumen, violently agitating the mass so as to bring the oil into contact with the mineral particles of the ore, causing the oil-coated mineral particles to rise and float on the surface of the water, while the gangue sinks to the bottom, and lastly skimming the floating concentrate from the surface of the liquid. But the appellees say that the Froment patent is a paper patent, and that therefore it is to be disregarded. A paper patent, if it fully describes an invention, whether it be a machine, device, or process, is just as effective to show anticipation as a patent which describes an invention which has gone into extensive use, for a presumption of operativeness and of some utility attends the granting of Letters Patent. *Packard v. Lacing Stud Co.*, 70 Fed. 66; *E. L. Watrous Mfg. Co. v. American Hardware Mfg. Co.*, 161 Fed. 362; *National Chemical & Fertilizer Co. v. Swift & Co.*, 104 Fed. 87, 91; *Universal Winding Co. v. Willimanitic Linen Co.*, 82 Fed. 228; *Van Epps v. United Box Board & Paper Co.*, 143 Fed. 869; *Ironclad Mfg. Co. v. Dairyman's Mfg. Co.*, 143 Fed. 512, 515; *Dashiell v. Grosvenor*, 162 U. S. 425, 432. In *Telephone cases*, 126 U. S. 1, 536, it was said: "The law does not require that a discoverer or inventor, in order to get a patent for a process, must have succeeded in bringing his art to the highest degree of perfection. It is enough if he describes his method with sufficient clearness and precision to enable those skilled in the matter to understand what the process is, and if he points out some practicable way of putting it in operation."

The fact that the appellees use a smaller quantity of oil than was used in the prior art is not of itself, and it is not claimed by them to be, sufficient to distinguish their process so as to render it patentable. To discover that the desired result may be accomplished with the use of a fraction of 1% of oil when formerly a much larger quantity of oil had been used, and had been deemed necessary, is not an invention or discovery

within the meaning of the patent laws. It is a difference of degree and not of kind. "A change only in form, proportions, or degree, doing substantially the same thing in the same way by substantially the same means with better results is not such invention as will sustain a patent." *Roberts v. Ryer*, 91 U. S. 150.

In *Fried. Krupp Aktien-Gesellschaft v. Midvale Steel Co.*, 191 Fed. 588, the court said: "But mere useful and economical administrative methods, however valuable, while they may, and usually are incident to invention, do not themselves constitute invention." And in *DeLamar v. DeLamar Min. Co. Ltd.*, 117 Fed. 240-248, this court, referring to the use of zinc dust for the purpose of precipitating mineral in a solution said: "The right to use the dust being free to all, we think it follows necessarily that all have a right to adjust the quantity of the material to the necessities of each case, and ascertain by experiment or analysis, if need be, the quantity that may be required to produce the desired end; that such a use cannot be made the subject of monopoly, there being involved in it no discovery, but only the exercise of ordinary prudence and skill." See also *Brady Brass Co. v. Ajax Metal Co.*, 160 Fed. 84; *Commercial Mfg. Co. v. General Electric Co.*, 149 Fed. 408; *Lauman v. Urschel White Lime Co.*, 136 Fed. 190; *Tilghman v. Proctor*, 102 U. S. 707; *Guidet v. Brooklyn*, 105 U. S. 550.

But it is said that the appellees' process is the only froth process, and that the processes described in the prior art are the bulk flotation or oil buoyancy process. We have to inquire, therefore, what is the oil buoyancy process. It is described in the Elmore patents, No. 676,679, issued June 18, 1901, and No. 689,070, issued December 17, 1901, and in the testimony of Mr. Ballantyne, general patent counsel of the appellees. Mr. Ballantyne said that it was essential to this process, first, that the oil should be thick and viscous, for otherwise the metal would easily fall out of the oil; second, that the process be carried out in the cold, because if the oil be heated, it becomes thin, and will not entrap or float the mineral; third, that the mingling of the pulp and the oil be as gentle as possible, so to avoid breaking the oil into globules. And the appellees' expert, Chandler, testified that in the oil bulk flotation, 15.7 parts of oil must be used to 6.7 parts of ore. With these definitions and explanations of the oil buoyancy process in view, it is very plainly to be seen that in none of the patents herein discussed, aside from the Elmore's, is that process used. The Haynes patent uses 11% of oil to the ore, and directs that the mixture be agitated with hot, warm, or cold water. Kirby recommends thorough agitation by rapid rotation of the agitator, and he refers to the floating concentrate as a "scum". The Everson patent declares that thorough agitation of the mass or pulp, comprising water, the finely divided ore, the oil of fat and the acid, is necessary, and in the *Engineering and Mining Journal* of November 15, 1890, there is an article describing a test operation of that process, in which it was said that as the result thereof "a thick scum of sulphurets rose to the surface and was skimmed off, leaving the hitherto black ore as white as snow; in fact, pure silica." And so in the Cattermole process, although its ultimate purpose was to precipitate the metal in the form of granules to the bottom of the tank, it was first required that the mixture be thoroughly agitated, and as the result thereof, a froth necessarily came to the surface.

Metal and Oil Froths

The contention is made, however, that if indeed the prior patents disclose froth processes, the scum which the appellees' process causes to rise to the surface of the water, is so different from the froth or scum which arises under the prior art, that it is a new result, and is not anticipated by anything in the prior art. Say counsel for the appellees: "You produce a froth which is not our froth," and again they say that the appellees' froth is "a pure metal froth", while that of the other patents is an "oil froth," and that the appellees' froth consists of air bubbles surrounded by metal armor without any appreciable quantity of oil connected therewith. The evidence in the case, together with the illustration thereof afforded by demonstration of the various processes which were made in the aid of the argument before this court, convince us that the froth in all these processes is the same, with the exception that there is less oil (as there must necessarily be) in the appellees' froth than in the others. The froths are all similar in appearance, they all rise to the surface after the same amount of agitation, they all gather with equal efficiency the same quantity of metal, and all may be removed from the surface in the same way. It is not literally true, of course, that there is no oil in the froth which the appellees produce. If there were no oil in it, there would be no froth. The quantity of oil that has been put into the mixture must necessarily be found in the froth. It would manifestly be a physical impossibility to

create a froth consisting only of bubbles of air and the particles of mineral. This is admitted in the specifications of the appellees' patent, in which it is said that there must be agitation "until the oleic acid has been brought into efficient contact with all the mineral particles in the pulp," and that the air bubbles which make the scum floatable adhere "only to the mineral particles which are coated with the oleic acid."

It is said in the appellees' brief that one feature of the froth produced by their process is that it is unnecessary to clean the mineral of the oil, as the infinitesimal oil coating has no adhesive effect, and that the concentrates may be freely tumbled or vanned, and counsel say: "All you have to do is to gather that froth from these vessels, dry it out, and take it to the smelter." We find no evidence in the record that the froth which the appellees produce may be smelted without removing the oil therefrom, or that it would be a distinct advantage to do so, or that the froth produced by some of the anticipating processes may not be taken to the smelter without removing the oil. If the statement made in the brief is true, it is very clear that that feature of their froth was not known to the patentees at the time of their application for the patent, and is nowhere disclosed in the specifications or claims. The specifications deal only with the production of the scum or froth, but claim 13 includes "filtering off the froth and removing the oleic acid therefrom by treatment with an alkali," and on May 3, 1905, in a statement of their method of oil concentration which they sent to Australia, the patentees said, "The oleic acid is therefore of necessity recovered in the process and in the state in which it is required for re-use. This is not undertaken merely for the purpose of recovering the oleic acid, but as a necessary step in rendering the concentrates fit for vanning, separation into blende and galena."

Decision of the Lower Court

The decision of the court below appears to have been largely influenced by the consideration that the appellees' patent had gone into extensive and successful use. The fact that a patented device or process has gone into extensive and successful use is often of value in determining the question of invention and patentability. It is referred to for the purpose of turning the scales in cases of grave doubt. It is of no value whatever where the question of invention or patentability is free from doubt, and in any case its value depends largely upon the causes which produced it. It is often due to business ability in manufacturing, exploiting, and advertising, and to the fact that prior conditions have not stimulated development. The appellees' process, originally patented in Great Britain, has been installed in Australia, Sweden, Finland, Chile, and Wales, and it is in the process of installation in Cuba. It is not improbable that in those countries the prior art may have been substantially unknown, and it is possible that the appellees' success there is referable to the fact alleged in the bill, "that the complainants have been to great trouble and expense in the introduction into use of the process, and have invested large sums of money in its introduction into commercial use in different parts of the world, and in the effort to introduce it into commercial use in the United States." It is in evidence that in making the process known to the public in the United States, the appellees have expended \$60,187. Notwithstanding these efforts and expenditures, their process has not yet been installed in the United States. In *Olin v. Timken*, 155 U. S. 141, 155, it was said: "While the patented article may have been popular and met with large sales, that fact is not important when the invention is without patentable novelty." In *McClain v. Ortmyer*, 141 U. S. 419-428, the court said that "the extent to which a patented device has gone into use is an unsafe criterion even of its actual utility, is evident from the fact that the general introduction of manufactured articles is as often effected by extensive and advantageous advertising, activity in putting the goods upon the market, and large commissions to dealers, as by the intrinsic merit of the articles themselves."

It would serve no useful purpose to review all the numerous decisions in patent cases that are cited by the appellees. But we will refer to two of them which seem to be especially relied upon—*Naylor et al. v. Alsop Process Co.*, 168 Fed. 911, and *United States Mitis Co. v. Midvale Steel Co.*, 135 Fed. 103. In the first of these cases, the court held that an expert cannot take a process patent which has never been applied industrially and work the process in his laboratory, and discover therefrom something which is not disclosed on the face of the patent and then transfer that experience back to the time of the patent, and make it a part of the prior art for the purpose of defeating a subsequent patent for a meritorious invention. There is nothing in the present case to which that ruling applies, and it is to be observed that the court sustained the patent in that case expressly upon the ground that the com-

plainant therein was the first to discover a successful process for bleaching flour. The court said: "His act was not selection of known agents in the art of bleaching flour, but was the discovery of the only agent that has yet been found to accomplish that result successfully in the milling industry." The second case is said by counsel for the appellees to be "conclusive." The invention there under consideration was a process for making steel castings homogeneous so as to prevent blow-holes, and it consisted in adding to the molten steel when it is about to be poured into the mould, a minute quantity of metallic aluminum. But the distinction between that case and the case at bar is plainly to be seen in the fact that there the inventor made a distinct addition to the known art. He added something which has not been used by others, and which was effective in producing the result which was sought. In the present case nothing has been added.

The Decision

We hold that to sustain the appellees' patent would be to give to the owners thereof a monopoly of that which others had discovered. What they claim to be the new and useful feature of their invention, as stated by their counsel, is "agitating the mixture to cause the oily coated mineral to form a froth." As we have seen, that feature was clearly anticipated by the prior art, and when the elements of the appellees' claims are read one by one, it will be found that each step in their process is fully described in more than one of the patents of the prior art, with the single exception of the reduced quantity of oil which they use. The patentees of the appellees' patent made a valuable contribution to the art in discovering the smallest quantity of oil which would produce the desired result. In doing so, they pursued the course which all skillful metallurgists would be expected to pursue. They made a series of experiments to determine how small a quantity of oil could be used successfully. They found, as all must find who apply the oil flotation process, that certain oils are adapted to use with certain ores, and that a larger quantity of oil is necessary for one kind of an ore than for another. The appellees admit that for some ores they use four times as much oil as for others. Their discovery that a small fraction of 1% of oil is sufficient to produce flotation of the metalliferous matter cannot, as we have seen, be made by itself or in combination the subject of a patent. The appellees cannot take from others the right to use oil economically. This was evidently the ruling of the Patent Office on their application for a patent. One of their claims in the original application was "the process of concentrating powdered ore, which consists in separating minerals from gangue by coating the minerals with oil in water containing a fraction of 1% of oil in the ore, and recovering the oil coated minerals." This was rejected in view of the Cattermole patent "as expressing merely a difference of degree thereover as to the proportion of oily matter employed." Counsel for appellees admit that the claim was properly rejected for the reason that it leaves out the agitation and froth, and say "our invention is something else than the mere reduction of oil."

The decree is reversed, and the cause is remanded with instructions to dismiss the bill.

Rhodesia is much the same size as Mexico and has an area of about three-quarters of a million square miles. The government of the country is in the hands of the British South Africa Co., which administers by virtue of the Royal Charter granted them in 1889. The charter must be renewed during the present year, and practically all of the residents of Rhodesia are much in favor of such a renewal rather than the absorption of the territory as a part of the Union of South Africa. Rhodesia is less Dutch than other parts of British South Africa, and herein lies the main reason for a desire for a continuance of independence on the part of Rhodesians.

Owing to the increase of magnetite in the Great Cobar ore, New South Wales, an abnormal loss of copper has occurred in the slags, and to minimize this a reverberatory settler has been installed, which is expected to materially improve the recovery.

THE SUAN MILL.

Gold Mining Concessions in Korea

By A. E. DRUCKER

Three gold-mining concessions in Korea granted to foreigners are now on a dividend-paying basis: the Oriental Consolidated, Suan Concession, and French Concession.

Oriental Consolidated

This concession, which consists of some 600 square miles in the northwestern part of Korea, is the pioneer in the successful working of low-grade mines in the Far East. During the fiscal year 1913 this Company milled 313,701 tons of ore (\$6.39 per ton of 2000 lb.) having an assay value of \$2,005,462. The net total bullion yield was \$1,629,323, indicating an extraction of 81.3%. Bullion secured by amalgamation was \$988,714, or 49.3%. By cyaniding concentrate, \$640,609, or 32.0% was recovered. The total operating expenses were:

| | Total. | Per ton. |
|-----------------------------|----------------|----------|
| Mining | \$ 610,212.19 | \$1.95 |
| Milling | 168,657.32 | 0.54 |
| Cyaniding concentrate | 107,391.98 | 0.34 |
| Ore transport | 3,601.59 | 0.01 |
| General expense | 126,915.12 | 0.41 |
| Total | \$1,016,778.20 | \$3.25 |

The total operating profit was \$644,698. The ore produced by this Company from the granting of the concession to June 30, 1913, makes a total of 3,236,216 tons, at \$6.14, equal to \$19,858,339. Dividends paid on shares to June 30, 1913, equal 115% or \$4,932,910.

At the present time dividends amount to 10% per year. The Company is capitalized for \$5,000,000 in 500,000 shares at \$10, of which the issued capital amounts to \$4,293,900. On July 1, 1913, there were estimated ore reserves to the amount of 805,900 tons containing \$4,488,800.

The re-grinding cyanide plant at Taracol was completed about the middle of May 1912, but did not operate steadily until the following month. This all-sliming and cyanide-agitation plant was erected to take the place of the old 18-day leaching process, treating concentrate only.

The months of June, July, August, November, December 1912, January and February 1913, a total of seven months, were under my direct supervision, the results being as follows:

| | |
|---|-----------------------|
| New plant: | |
| Tons treated | 14,899 |
| Assay-value per ton | \$25.08 |
| Total value | \$373,687.90 |
| Bullion secured | 338,622.25 |
| Actual extraction, per cent..... | 90.6 |
| Indicated extraction, per cent..... | 88.2 |
| Assay-value of tailing | \$2.95 |
| Increased extraction over old 18-day process: | |
| Actual | 6.6% = \$1.66 per ton |
| Indicated | 7.2% = \$1.80 per ton |
| Operating expense per ton, \$3.05. | |

During the last four years of the old leaching plant

the average actual extraction was 84% on an average heading of \$25.12. The average assay-value of the tailing in 1910-1912 was \$5.06, and the indicated extraction 81%. If the old 18-day process had been in use during the past fiscal year, 1913, the expense per ton would have been more than in the previous years (in 1912 it was \$1.47), since labor and supplies have increased in price. The Kuk San Dong old leaching-plant during the past fiscal year shows an increased operating expense of 30 to 40c. per ton over former years on a similar tonnage. Therefore, in comparing operating costs between the former and present method of treating concentrate at Taracol, it is reasonable to add at least 20c. to the former cost of \$1.47 per ton, making a total of \$1.67. The old process at the present time could not operate for less than that amount.

During seven months the all-sliming process treated 14,899 tons, with the following results:

| | |
|------------------------------------|----------------|
| Increased bullion extraction | \$1.66 per ton |
| Increased operating expense | 1.38 per ton |
| (3.05 — 1.67 = 1.38) | |
| Net profit | \$0.28 per ton |

The last Company report, June 30, 1913, states that the operating expenses for this plant will be reduced by the use of electric power instead of steam during the coming year.

One interesting metallurgical problem has been

solved in the re-treatment of the old sulphide concentrate tailing-dump at Kuk San Dong. This is the residue from the old cyanide leaching-plant, and represents the sulphide product originally caught on Union vanners. During the past fiscal year, this dump material averaged \$5.80 per ton, and 16,963 tons valued at \$98,371 was re-treated, yielding bullion to the value of \$68,508 (70% extraction). The total operating expense was \$2.39 per ton.

The manager in his report for the year ended June 30, 1913, states: "The plant ran successfully and made a profit of \$27,822.63, which has been credited to the cost of the plant, because the expenses of this construction were charged against the dump. There still remains \$10,749.03 to be earned before the plant has entirely paid for itself. During the coming year the plant is expected to yield a nice net profit."

This dump re-treatment process was originally proposed to the management during 1908 by myself, after concluding a long set of tests at the Taracol experimental plant. The above described plant at Kuk San Dong was designed and erected by me and began operating during May 1911. Original investment and cost of plant was \$39,336.

The figures on the next page are taken from the Company's annual reports and show dump material remaining from which a profit is expected.

VIEWS OF THE FRENCH CONCESSION, SHOWING THE NEW MILL, AN OLD KOREAN STAMP-MILL, A STAMP-MILL AND CYANIDE PLANT, AND NATIVES WASHING GOLD.

| | Tons. | Assay-value. |
|---------------------------------------|--------|--------------|
| Old dump remaining June 30, 1912..... | 27,790 | \$223,964.33 |
| Added dump during year 1913..... | 4,826 | 34,401.09 |

| | | |
|-------------------------------------|--------|--------------|
| Total | 32,616 | \$258,365.42 |
| Less year 1913 dump re-treated..... | 16,963 | \$ 98,371.31 |

Dump remaining June 30, 1913..... 15,653 \$159,994.11

The following is an estimate of a possible net profit to be derived from the Company's figures, assuming that the extraction and operating cost per ton will remain as above:

| | |
|---|--------------|
| 70% on \$159,994.11..... | \$111,995.87 |
| \$2.40 per ton cost on 15,653 tons..... | 37,567.20 |

| | |
|--|--------------|
| Gross profit | \$ 74,428.67 |
| Remaining amount to be paid on plant | 10,749.03 |

Net profit

I am very glad to hear at the present time that the cost of this plant has been entirely paid out of the monthly operating profits, and that the original money invested (\$39,336) has been re-gained. The results of 1914 should be good, and up to expectations. Credit is due the manager, superintendent, and foreman in charge for their efforts. I have already described the results and operations of some recent plants constructed by the Oriental Consolidated in the *Mining and Scientific Press* of November 23, 1912.

Suan Concession

This concession, operated by the Seoul Mining Co., is situated about 50 miles due east from Pyeng Yang, the second city in population in Korea. At the present time the Suan is the only producing mine on the concession; however, the Tul-Mi-Chung mine has been sufficiently developed to supply a 20-stamp mill for a considerable time, and will become productive as soon as a plant is installed. I understand that a plant is being designed, and work on it will begin shortly.

The authorized capitalization of this Company is \$500,000 (5000 shares at \$100 each), and the issued capital amounts to \$400,000. Dividends to the amount of \$400,000 had been paid up to November 1912, or 100% to the holders of the issued shares. The actual operating costs, revenue, and gross profits at the Suan mine during 1912 were:

OPERATING EXPENSES (PER TON MILLED)

| | |
|--------------------------------------|--------|
| Ore milled, tons (2000 lb.), 74,432. | |
| Mining and development | \$1.68 |
| Milling and ore transport | 0.78 |
| Concentrate expense | 0.31 |
| Shipment of smelting ore | 0.02 |
| General expenses | 0.75 |
| Total | \$3.54 |

REVENUE (PER TON MILLED)

| | |
|-------------------------------|--------|
| Bullion by amalgamation | \$6.34 |
| Concentrate shipped | 1.89 |
| Smelting ore shipped | 0.08 |
| Bank interest | 0.02 |
| Total | \$8.33 |
| Operating profit, \$4.79. | |

Gold, copper, and bismuth are the valuable metals contained in the Suan ore. Copper occurs mainly as chalcopyrite; some tetrahedrite and bornite also are to be found. Gold is alloyed with a small quantity of silver, and is rarely found in a coarse condition.

The metallurgical method employed is amalgamation and concentration, the concentrate being shipped to England for treatment. The ore passes through stamps, Pierce amalgamators, over plates, through a second set of Pierce's, tube-mill and Pierce's, and thence to concentrating tables and a canvas plant. The tailing is allowed to flow to waste. The sources of gold recovery by amalgamation are approximately as follows:

| | % |
|---------------------------------|-------|
| Mortars | 5.0 |
| Upper Pierce amalgamators | 79.0 |
| Copper plates | 1.0 |
| Lower Pierce amalgamators | 4.4 |
| Tube-mill and Pierces | 6.0 |
| Miscellaneous | 4.6 |
| | 100.0 |

The concentrate obtained from the concentrator plant amounts to about 1% of the ore milled. It contains gold, silver, copper, and bismuth (2.24%). The sum obtained from the smelter on bismuth alone amounted to \$19,025 during 1912.

For 1912 (1913 figures not being available) the following results were obtained:

| | |
|------------------------|--------|
| Ore milled, tons | 74,432 |
| Assays: | |
| Gold | \$8.53 |
| Copper, per cent | 0.89 |
| Tailing: | |
| Gold | \$1.30 |
| Copper, per cent | 0.65 |
| Extraction: | |
| Gold, per cent | 86.2 |
| Copper, per cent | 20.34 |

Owing to the presence of copper and bismuth in considerable quantities, thus preventing the successful application of the cyanide process, the treatment of the ore is necessarily complex. The sulphide has a tendency to slime readily, making concentration difficult. It is mainly a problem of efficient classification and slime concentration. The Company realizes that the net recovery by the present methods of reduction is not entirely satisfactory; consequently it has engaged Walter G. Perkins & Co., metallurgical engineers, to advise and carry out alterations in the plant.

The ore reserves of the Suan mine are sufficient to supply the present 40-stamp mill for 3½ years. This Company has been well organized and managed. It is paying a regular yearly dividend of 50% on an issued capital of \$400,000.

French Concession

This was granted to P. M. Saltarel, of Paris, during 1901 by the Korean government. The mineral, timber, and water rights are to extend over a period of 25 years from that date. Practically nothing was done with it up to 1911 by the owner. Prior to that date

several engineers had made examinations, but all reports were unfavorable. I believe that it was during the latter part of 1910 and the first part of 1911 that the Koreans made discoveries of rich gold ore at what is now called Small Nurupi and Nurupi mine. Koreans flocked to this new gold discovery in large numbers and constructed primitive wooden stamp-mills and cyanide plants. A considerable quantity of gold was recovered by these crude methods, but a great deal was lost.

During the latter end of 1911, L. Rondon & Co., of Seoul, Korea, secured a lease from the owner to extend

is at the present time being worked by many Koreans on the concession by primitive methods.

This concession has been poorly managed through pure ignorance of the mining business. Under good management there is no reason why it should not be one of the most productive in Korea.

Costs and Recovery at Wasp No. 2 Mine and Mill

This mine is situated in South Dakota, and during 1913 the mill treated 127,680 tons of ore yielding \$1.718 per ton in a dry-crushing cyanide-leaching mill of 15,000 tons monthly capacity. The ore is mined in open-cuts, the body lying nearly horizontal, in a bed 20 ft. thick, covered by as much as 14 to 18 ft. of soil, sandstone, and shale. This overburden is handled largely by steam-shovel. Costs were as follows:

COST PER TON

| | | | |
|----------------------|----------|-----------------------|----------|
| Mining: | | Superintendence ... | 0.0196 |
| Labor | \$0.2965 | Expense | 0.0087 |
| Stripping | 0.1404 | Coal | 0.0087 |
| Supplies | 0.0409 | Cyanide | 0.0782 |
| Power | 0.0199 | Zinc | 0.0332 |
| Explosives | 0.0720 | Lime | 0.0077 |

*Calculated at 59.25c. per fine ounce.

over the remaining years for which the concession was granted. This Company is now operating a 20-stamp mill and cyanide plant, the operating profit being from \$15,000 to \$20,000 per month. From January 1 to April 1, 1913, a 5-stamp mill and cyanide plant produced \$39,887 in gold bullion, from April 1 to August 1, \$77,873 with 10 stamps, and from that time an additional 10 stamps have been operating. The cyanide plant has been increased to twelve 30-ft. leaching-vats.

The slime product from the mill that has been collected in ponds for a future treatment will assay from \$12 to \$18 per ton. A great deal of valuable material is being stored here awaiting the completion of a slime-treatment plant, which will add materially (20%) to the monthly bullion production. Prior to May 1913 a considerable quantity of this rich slime was allowed to flow into the river. It is also expected to add another 10 stamps to treat rich tribute ore, that which

Labor troubles are still of frequent occurrence in Australia. Official figures for 1913 show that there were 208 disputes of all kinds, involving employees over 10 in any establishment, and totaling 50,283 people. The men-working days lost were 622,535, who lost about \$1,400,000 in wages. The wages paid in manufacturing industries is 20% of the value of the output, so the loss in products was about \$6,800,000. The disputes were characterized as stupid and unreasonable demands.

KUK SAN DONG DUMP PLANT AND ORIENTAL CONSOLIDATED MILL.

Leaching of Copper Tailing

By RUDOLF GAHL

*The electrometallurgy of copper is mainly hydrometallurgy, inasmuch as the electric current is used principally for the deposition of copper from its solutions. Up to the present time the application of the current has been confined to the precipitation of copper from solutions originating from metallic copper, in other words to the electrolytic refining of copper, but the application of electricity to copper solutions resulting from ores is being constantly advocated, and as a matter of fact, is being tried in several places on a small scale. The necessary basis for electrolytic precipitation of copper extracted in leaching operations is naturally a successful application of leaching methods, and from this standpoint a presentation of experimental results in this line may be justified for an electrochemical meeting, although the electric current was not used in these tests for the precipitation of copper.

Leaching Carbonate Ores

The leaching of carbonate ores of copper has been attempted repeatedly, but has not been a commercial success, except in some isolated cases, as for instance in the case of the Arizona Copper Co., at Clifton, where such leaching operations have been carried on for a great number of years. The frequent failure of such attempts may have been the cause for the general distrust of leaching operations that prevailed among engineers up to a few years ago. Recently this sentiment has changed considerably and leaching plants of large size are being planned. I might mention in this connection the projected Chuquicamata plant in Chile and the Ajo project of the Calumet and Arizona, where it is intended to leach oxidized ores by sulphuric acid.

Engineers are no longer afraid of giving their attention to the hydrometallurgical treatment of sulphide ores, as for instance the porphyry copper ores. Here the milling of these ores has been undertaken on an enormous scale, the gravity concentration process by which they are treated has been the subject of extensive study at the plants. While this research work has shown ways for essential improvements which, for instance, make the concentration of ores possible that nobody would have thought of milling some years ago, it has, on the other hand, clearly defined its limitations.

The concentration process has been developed to such a state of perfection that on clean sulphide ores recoveries of 85% of the copper can be obtained. Unfortunately the ores that generally are called porphyry copper ores are not of this character, as they contain a considerable percentage of their copper in the oxidized state. This is undoubtedly partly due to the fact, that

the limits between sulphide and oxidized ores are not very sharp or are not followed exactly when the ore is mined. On the other hand most of the orebodies that are mined at present are to some extent altered by oxidation.

The water concentration process is, up to the present time, not able to extract copper in oxide combination with an efficiency, approximating the extraction of the sulphide copper. I believe that 30% is an average round figure for the extraction effected on the oxidized portion of the copper in sulphide ores. It follows, that where ores are largely contaminated with such material, no satisfactory saving can be obtained by ordinary concentration methods. A great many of the mines in Arizona and New Mexico suffer from this disadvantage.

The natural consequence has been, that the copper mines have been looking lately toward a hydrometallurgical method to improve the copper extraction. It is being advocated by some to discard the time-honored concentration method and to supplant it by an altogether different treatment. They suggest to roast the ore, to leach the calcines and to precipitate the copper from the resulting solution. Electrolytic precipitation is favored by many, although it is maintained by others that the precipitation of copper from so low-grade solutions as would naturally result from leaching very low-grade ores is a problem which so far has not been solved by electrochemistry. Although replacing the concentration process by a process of the kind indicated at one of the prominent Western mines would mean a radical departure, it must be kept in mind, that similar processes have been in constant use for a long time both in Europe and in the East of the United States. The Pennsylvania Salt Mfg. Co. has produced copper in such a way for years.

Leaching Concentrates

The class of copper metallurgists which may be called the conservative party have confined themselves to supplementing the concentration process by hydrometallurgical methods. This can be done by leaching the concentrate, which I understand is being tried at the Braden Copper Co., and by leaching the tailing. The latter is the more important, inasmuch as it adds to the extraction effected by the concentrator. To this class belongs the system of leaching worked out by Laist at the Anaconda, the tests with the Bradley process also at Anaconda, and tests undertaken at some of the Arizona mines.

One test I made at Morenci, Arizona, in connection with the concentrating plant of the Detroit Copper Co. The ore has the characteristics of the porphyry copper ores, being perhaps oxidized and kaolinized to a

*Abstract from a paper presented at the twenty-fifth general meeting of the American Electrochemical Society, in New York City, April 16-18, 1914.

higher degree than other ores of the class. The principal copper mineral is chalcocite. Some chalcopyrite and some pyrite accompanies it. In concentrating, ores of this character behave in a typical way. The resulting sand tailing is always low in copper or can be reduced to a low figure by ordinary milling methods, that is, regrinding and reconcentration. The slime tailing, however, is high in copper content, and no standard method of milling is available to reduce it materially. This is attributed to the accumulation of oxidized material in the slime. The oxidized portion of the ore has evidently a greater tendency to form slime than the sulphide portion, and as the recovery in oxide copper is very low, it is a common thing to find more oxide than sulphide copper in the slime tailing. It was attempted in the experiments to recover the oxide copper in an economical way by leaching with dilute sulphuric acid. It is due to the confidence which C. E. Mills had in the outcome, that a suitable testing plant was built in which this experiment could be made.

Filtration and Decantation

Successful leaching not only depends on getting the copper into solution, it depends just as well on the separation of liquids from solids and on the precipitation of copper from the resulting solutions. In this case the second step seemed especially difficult, as the slime in question is very colloidal in character and behaves almost like clay. Filtering costs with this slime would probably have been prohibitive, not even considering the extra costs which the acidity of the solution would have imposed.

For this reason I looked toward a decantation method which would suit this particular purpose. Such method, in addition to eliminating the difficulty in question, would also offer an advantage over filtering.

It was found in preliminary copper leaching experiments, that it is more economical to leach in steps, that is, to leach fresh ore first with a solution high in copper and low in free acid, to replace this solution by another one lower in copper and higher in acid, to finish the leaching with a solution still lower in copper and higher in free acid. This reduces the consumption of chemicals and raises the extraction. It has also another advantage when the precipitation of the copper is effected by iron, as was the case in these experiments. By bringing nearly exhausted solution in contact with fresh ore, as described, the ferric salts are transformed into ferrous salts, and the consumption of metallic iron is reduced nearly to the theoretical limit. The loss of iron resulting from the entrance of ferric salts into the precipitating plant is thereby very materially reduced. Filtering methods do not lend themselves to a repeated change of solutions.

In cyanide plants there is no objection to using solutions resulting from the leaching operations in the milling department, as the cyanide has no detrimental effect on milling machinery. Crushing in cyanide solution is in fact frequently preferred. For this reason

it is possible to add the fresh water (which is required to make up for the water going to waste with the tailing) in the cyanide department and to send an equivalent amount of cyanide solution to the milling department. In the cyanide department the fresh water can be used for washing the tailing resulting from the leaching operations, which is the ordinary practice.

FIG. 1 AND 2.

It is not possible, however, to do this, when leaching is conducted with sulphuric acid. The resulting solutions, being unfit for use in the mill, have to be retained in the leaching department. As new quantities of water enter the leaching department all the time, solutions would accumulate, if the attempt were made to use fresh water for washing. For this reason the barren solutions coming from the precipitation plant are essentially the only ones that are available for washing the settled pulp.

Keeping in mind, that no fresh water can be used in leaching copper tailings, it follows, that the leaching plant has to be independent of the mill and that no circulation of solutions must take place between the two. The flow-sheet of the leaching plant has to be essentially a closed circuit. The only thing to do then with solutions, as they would result from counter-current leaching would be to send them to a precipitation plant and from there, having added fresh acid, to the last tank, as shown in Fig. 1.

This flow-sheet can be changed in such a way, that the objections raised against the system are obviated. Fig. 2 shows the resulting modification. Two more tanks, the number, of course, is not essential, are added to the system and serve for washing purposes. The solution discharging from the precipitating plant is sent to the last tank of the series and passes through the series of tanks in counter movement to the pulp. Comparing Fig. 1 with Fig. 2 it is evident that there is no difference in the flow sheets except regarding the condition of the pulp at various points of the system.

I might call attention to the possibility of applying heat to a system like this, although no use has been made of artificial heat in the experiments made with this plant. If heat in the form of steam or otherwise is applied at the same point or near the point, where the acid is added, as marked in Fig. 2, the temperature, after equilibrium is reached, will drop toward the end of the system, as will easily be seen by tracing the way in which the heat distributes itself. Accordingly only part of the heat introduced escapes with the tailing pulp, while the rest serves to pre-heat the inflowing pulp.

The Addition of Acid

I have been emphasizing the importance of adding acid in the most suitable place of the system. To anyone who has used similar methods in cyaniding gold and silver ores, it may seem as if this point would not deserve so much consideration. But there is a radical difference between copper leaching and cyaniding in regard to this point. In cyaniding there is always a large excess of the leaching agent over the quantity which is required to combine with the metal which is contained in the ore treated. The cyanide solution charged with gold and silver will pass through the precipitating plant and emerge from it as a solution which is available as leaching liquor again. The loss in cyanide is so small, that it can be made up in almost any part of the circuit without causing much difference in the extraction. Conditions are different in copper leaching. The solution leaving the precipitating plant is useless for leaching purposes. This means, that sufficient acid has to be added to make it a solvent for copper minerals, and it is, of course, of utmost importance to add this acid where it will accomplish most good.

I will not describe in detail the plant which was constructed along the lines indicated in the flow-sheet. It may suffice to state, that it consisted of a series of ordinary settling and small agitating tanks of the simplest kind. The pulp was transferred by gravity, the solution was circulated by air-lift. A launder filled with scrap-iron served as a precipitating plant. The plant treated between 7 and 10 tons daily for a period of 50 days continuously. It was closed down only for very short intervals and only when owing to shut-downs of the concentrator the feed for the leach-

ing plant gave out. One unskilled laborer per shift was sufficient to operate the plant; in fact, would be for a large plant, except when it was necessary to remove the cement copper and to add iron in the precipitating plant.

The conditions of the tests were varied, as far as quantity of acid and tonnage are concerned. No heat was applied. Under the best conditions a recovery of 60% of the copper contained in the slime tailing was obtained from material containing 1.24% Cu. The 60% of the copper extracted represents the copper existing in the oxidized state. A higher extraction could have been obtained by using ferric sulphate in connection with sulphuric acid. Methods for cheap production of this salt were worked out in the laboratory, but have not been tried on a larger scale.

Operating Costs

The probable operating costs of a leaching plant for slime tailing were calculated on the basis of the experiments, with a certain margin for safety. They are represented in Table 1. The slime tailing being ordinarily a waste-product was considered not to cost anything.

TABLE I.

Probable Cost of Leaching Tailing Slime per Pound of Copper Delivered at New York.

| | |
|---|--------|
| 3.50 lb. acid @ \$10.00 per ton H_2SO_4 | 1.75c. |
| 1.50 lb. of scrap iron @ \$19.00 per ton..... | 1.43c. |
| Power | 0.25c. |
| Labor and repairs | 1.00c. |
| Smelting, refining, transportation of Cu, including losses in smelting, etc. | 2.00c. |
| Interest and depreciation of plant | 1.00c. |
| Total | 7.43c. |

The figures are based on conditions prevailing at Morenci, Arizona, where the tests were made. Owing to the situation of this mining camp freight rates are rather high.

The acid consumption is taken at 3.5 lb. H_2SO_4 , instead of 3.16, the figure obtained in the tests. The rate of \$10 per ton of H_2SO_4 is based on the assumption, that it would be possible to obtain the acid from a near-by smelting centre, where large quantities of ores high in sulphur are roasted.

The iron consumption was assumed to be $1\frac{1}{2}$ lb. of scrap iron instead of 1.25 lb. pure iron. The price of the scrap iron is so high because it has to be hauled from eastern Texas.

Owing to the relatively small scale on which the experiments were carried out, it was impossible to ascertain directly the power consumption for large-scale operations. It was estimated from figures about power consumption of air-lifts and agitation found in textbooks, etc. Power cost was assumed to be 36c. per hp. day.

Labor for leaching was found to be, and repairs were expected to be equally negligible for a well-constructed plant. Labor and repairs in connection with

the precipitation were based on what it was thought could be accomplished in a copper precipitation plant, the operating cost figures from which were available.

Smelting, refining, transportation of copper, etc., is based on the assumption that the smelting of the precipitate would be done in converters and includes the losses to be expected by this treatment. Interest and depreciation of plant is hard to approximate without making definite plans. The figure assumed may serve as an upper limit, however, and may be ample enough also to include taxes and a proportionate share of general office expenses.

As mentioned above only 60% of the copper contained in the slime tailing was extracted by leaching with dilute sulphuric acid, as the rest of the copper existed in the form of sulphide which is not acted upon by dilute sulphuric acid. Since making these tests the flotation process has been applied to ores of similar character and it has been found that it effects a very much higher extraction on the sulphide portion, an almost negligible one on the oxide portion of the copper. It follows, that tailing from flotation plants are lower in sulphide and higher in oxide copper. The fact has also been established that the oil used in the flotation treatment of ores does not interfere with a subsequent leaching of the tailing, it evidently does not attach itself to particles of oxidized copper minerals.

It seems that the conclusion may be drawn with safety that for certain classes of copper ores a combination of a flotation and a leaching process constitutes a metallurgical treatment which it will be difficult to surpass by other metallurgical processes in efficiency and cheapness.

Costs and Ore Treatment at the Broken Hill South Mine

During the second half of 1913, this mine produced 170,080 tons of ore, of which 168,957 tons was treated. The cost of mining was \$2.93; filling stopes, 25c.; development, 85c.; and concentrating, 98c.; a total of \$5.01 per ton. The mill products were as follows:

| Product. | Weight, tons | —Metal content— | | Silver, oz. |
|----------------|-----------------|-----------------|---------|----------------|
| | | Lead, % | Zinc, % | |
| Concentrate | 27,594 | 68.1 | 6.6 | 24.4 |
| Zinc tailing | 107,279 | 3.5 | 17.6 | 3.6 |
| Quartz tailing | 12,409 | 1.3 | 5.3 | 1.4 |
| Slime | 21,675 | 9.6 | 14.8 | 7.5 |

The metal content of the concentrate was 18,782 tons of lead, 673,465 oz. silver, and 1814 tons of zinc. The recovery by concentration was 75.8% lead, 54.2% silver, and 7.4% zinc. The zinc tailing delivered to the De Bavay and Zinc Corporation flotation plants was 122,635 and 29,405 tons respectively. With the recovery from the 107,279 tons of zinc tailing produced and sold, the total extraction was 91% lead, 85.6% silver, and 84.2% of the zinc. A selective flotation plant to treat the current and accumulated slime is being erected. The first unit will be of 500-ton weekly

capacity. The ultimate capacity will be 1000 tons of current and 1000 tons of accumulated slime per week. A sulphuric acid plant of 70-ton weekly capacity is also to be erected.

Costs at the Montana-Tonopah Mine

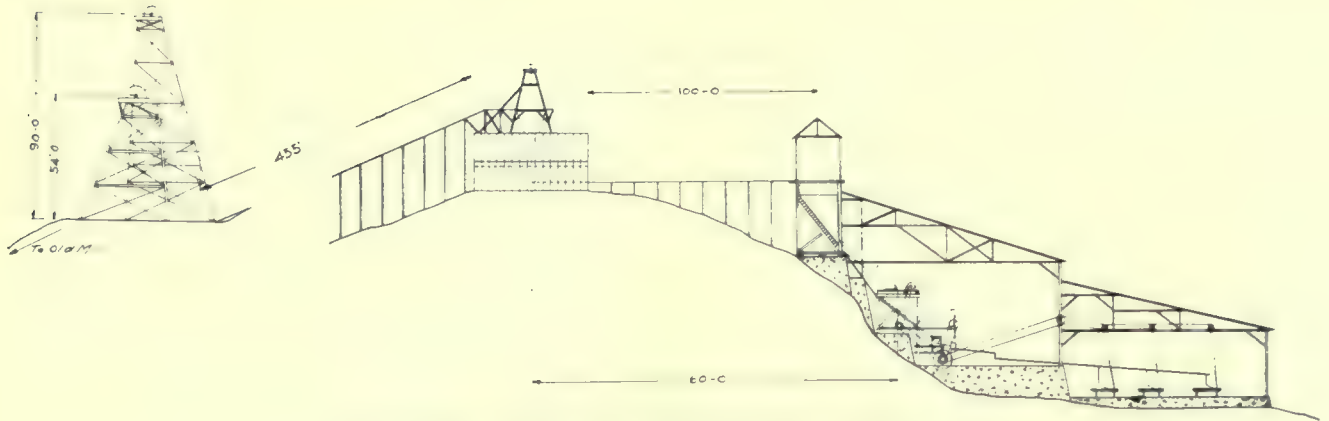

During the year ended August 31, 1913, development totaled 10,243 ft. at a cost of \$1.364 per ton. Mining 52,362 tons of ore cost 72.3c. per ton for breaking, 36c. for hoisting and dumping, 79.4c. for tramming and shoveling, 45c. for timber and labor in handling it, and 29.3c. for supervision, machines, tool sharpening, surveying, assaying, etc., a total of \$2.62 per ton. This is 35.5c. lower than the previous year. At the mill 52,402 tons was treated during 348.5 days. The extraction of 91.2% is 1.2% over the last term. Costs were as follows:

| | Per ton. |
|---------------------------|----------|
| Crushing and conveying | \$0.118 |
| Stamping | 0.309 |
| Elevating and separating | 0.066 |
| Tube milling | 0.214 |
| Concentrating | 0.041 |
| Settling | 0.107 |
| Agitating | 1.144 |
| Filtering and discharging | 0.225 |
| Precipitating | 0.157 |
| Refining | 0.081 |
| Water pumping | 0.047 |
| Steam heating | 0.275 |
| Mechanical department | 0.029 |
| Water | 0.217 |
| Storekeeper | 0.016 |
| Assaying | 0.024 |
| Superintendence | 0.051 |
| Total | \$3.121 |

The cost of milling as compared with that of last year shows an increase of 16.1c. per ton, and the cost of cyanide shows 29.9c. per ton increase on account of the greater consumption. During the year no vanner concentrate was produced, as it was found that a considerable saving in cost could be made without reducing the extraction. Although the increase in the cost of milling and the greater consumption of cyanide is due to this change, on the other hand the cost of marketing bullion and concentrate has been reduced 31.5c. per ton of ore treated, and the extraction increased 1.2 per cent. A recent improvement in connection with the Butters filter-plant is expected to materially reduce the consumption of cyanide, and to increase the extraction. Other recent changes in different parts of the plant should result in increased efficiency and lower operating costs according to Arthur H. Lawry's annual report.

Scotch mineral oil companies produced about 75,000,000 gal. of oil of all kinds in 1913, and 20 collieries in the vicinity of Edinburgh had a yield of 4,000,000 long tons of coal.

All cars at the Daly-Judge mine, Utah, were fitted with manganese steel wheels in 1913.

PROPOSED PLANT OF THE ARGONAUT MINING CO., AT JACKSON.

Disposal of Residue From Amador County Mills, California

By M. W. VON BERNEWITZ

Everywhere millmen have been troubled with the disposal of residue, and even when the problem seems to have been satisfactorily solved, and some scheme or other is working well for years, somebody suddenly makes objection to residue covering land, or to dumps making too much dust. The problem is akin to that of dredging, hydraulicking, and neutralization of smelter smoke. The people of a suburb of Kalgoorlie, Australia once appealed to the mining magistrate to stop a large company from dumping residue near it. He, without hesitation, said that the mining industry in this instance was of paramount importance and the residents must put up with the encroaching dump. There are many places where mining is of first importance, though it is not always so held.

In the Mother Lode district of Amador county, where a number of large mines have been discharging their stamp-mill tailing into certain creeks for many years, until recently no objection has been made. The farmers in the lower part of the country have now, how-

ever, complained that their land is being destroyed. They have sought the aid of the courts, and the mining companies were given until December 1914 to devise schemes to abate the nuisance. As a result, considerable work is being done to stop tailing from flowing down Jackson, Sutter, and other creeks to the farming lands below. At or near Amador City are the Original Amador, Bunker Hill, and Fremont mills containing a total of 100 stamps, crushing nearly 500 tons of ore per day. This pulp has been flowing down various creeks, but is soon to be stored in ponds, allowing only clear water to get away. Between Sutter Creek and Jackson are the South Eureka and Oneida mills of 100 stamps, crushing 490 tons per day. The former Company has diverted its residue through a long flume and pipe to a dam, nearly three-quarters of a mile distant, and has storage room for a considerable time. At the Oneida the tailing is stacked near the mill, and fairly clear water runs down the creek to Jackson.

The Argonaut 40-stamp mill, crushing 200 tons per

GENERAL VIEW OF THE KENNEDY SURFACE PLANT, AND CONTOUR OF THE COUNTRY NEAR JACKSON. BEYOND THE 100-STAMP MILL ARE THE FOUR TAILING-WHEEL HOUSES AS DESCRIBED. MILL RESIDUE USED TO FLOW DOWN THE CREEK ON THE RIGHT.

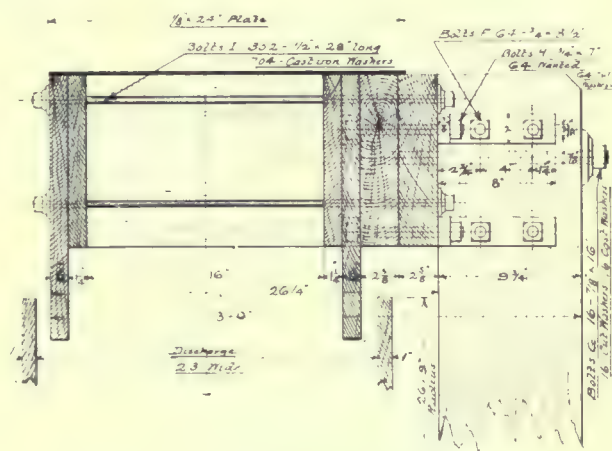

day, is situated on a hillside below the main shaft, and the problem involved elevating the residue by some method. It has been decided to erect a 50-stamp mill on top of a hill 455 ft. above the shaft. The ore hoisted by the new 90-ft. head-frame, the present one being 54 ft. high, and stored in a 250-ton bin, is to be taken to a 1,350-ton storage bin above the new mill by a gravity tramway using 2-ton skips in balance, aided by an electric hoist near the main shaft. The process contemplated is stamping, amalgamation, concentration, regrinding and amalgamating the 25% product over 60 or 80-mesh screens. Three Frue vanners will be used instead of two for each battery. The residue from this plant will flow by gravity to a site, which is ample for

about 25 years' storage without stacking.

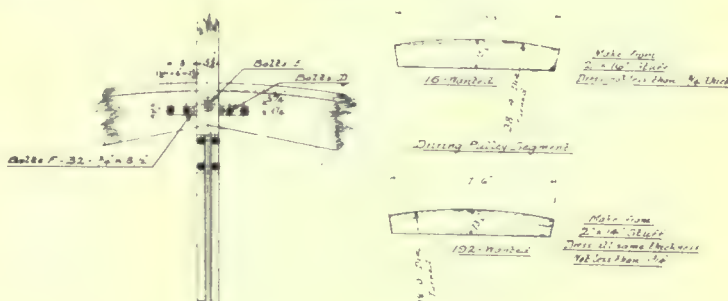

Opposite the Argonaut is the Kennedy plant of 100 stamps, crushing about 450 tons per day. This Company has a large dumping ground some distance from the mill, and the plant for disposal of residue may be described as follows: Across a creek from the plant has been built a wooden flume, 900 ft. long and 8 by 18 in. section, which is to convey the pulp to a tailing wheel 56 ft. diameter. This lifts it 36 ft. to a short flume, about 50 ft. long, and another similar wheel also elevating 36 ft. From this to a third wheel is a flume 800 ft. in length, and from this to the fourth and last wheel is another short flume, the pulp finally flowing down a valley and there stored. In short, the system

FRONT SECTION OF ONE-HALL OF A WHEEL.

DETAILS OF BUCKET AND END OF WHEEL ARM.

DETAILS OF WHEEL AND PULLEY.

includes a series of four wheels elevating mill tailing a total height of 144 ft., and its transportation a distance of 1800 ft. in all, including the flume from the mill to the first wheel. The grade of all flumes is 2.5%. The wheels are all identical in size and construction, being 56 ft. diameter and containing 176 buckets, each 16 in. long, with 11.99 in. pitch and holding two gallons of pulp. The axle or shaft is 11 in. diameter, and with the flanges weighs five tons. The wheel arms are braced by angle-iron to the flanges; and built up of segments on the arms carrying the buckets, is a 38-ft. driving wheel. Each wheel is driven by a 15-hp. motor, belted to countershaft and clutch gear, which drives the wheel by a 20-in. belt, and the wheel turns at 325 r.p.m. The construction work has been well done, and the scheme will cost about \$35,000. The

clear water from the settling pond may be used for irrigation work, or pumped back to the mill.

The accompany halftone and line-cuts show the complete plant and contour of the country, and some details of wheel construction which were designed by James Spiers of San Francisco.

Wheels for elevating pulp of any kind are not used much in the United States. At the Tonopah Mining Co.'s plant at Millers, Nevada, there is one 30 and one 45-ft. wheel working at low cost. At El Oro, Mexico, the El Oro Mining & Railway Co. has a large wheel in operation. On the Rand, wheels up to 80 ft. diameter have been greatly favored in the past. Although the first cost is high, they are reliable, and maintenance is low. Also in New Zealand and Western Australia this method has found great favor.

Valuing of Dredging Ground

By L. A. DECOTO

From time to time, and recently more than ever before, there has seemed to be a lack of the proper understanding of the valuing of a dredging area, and especially of the relation of the actual recovery from a small portion of the area as compared to the distribution of the gold throughout the entire area. With the aid of the accompanying theoretical plot and the resultant tables, I will endeavor to explain the point in question.

I will first consider the area, as a whole, on which 18 drill-holes have been bored. For convenience these holes have been numbered consecutively, the value or the gold content of each, in cents per cubic yard, placed above, and the depth of each, in feet, below the horizontal line and to the right of its number.

DIAGRAM SHOWING POSITION OF DRILL-HOLES.

Obviously, to obtain the average value or gold content per cubic yard for the entire area, it would be necessary to multiply the gold content of each hole by the depth of the hole, add the total of these products, and divide this sum by the total of depths of the holes. The resultant figure, in this theoretical case 37.69c., would be the average gold content per cubic yard, which would be the figure the examining engineer would report upon unless he used a safety factor to cover any possible loss in recovery by the dredge.

During certain periods in actual operation, the dredge will likely make a recovery above the average gold content per cubic yard, while for other periods the recovery may not reach the average gold content per cubic yard as reported by the examining engineer. These special cases are neither periods for undue rejoicing, on the one hand, nor for gloom on the other, but merely the expected sequence of events.

To further illustrate, cut the entire area, as per plot, into two parts, namely, one bounded by the test holes No. 1, 3, 8, and 6, calling it area A, and the other bounded by No. 9, 10, 16, and 18, calling it area B. Now determine the average gold content of the area A, by the process above described, and it will be found to be 72.42c. per cubic yard, and, likewise, the average

gold content of the area B is found to 12.72c. per cubic yard. It will readily be seen that neither the average gold content of the area A nor that of the area B, nor likewise a small portion of either, when considered by itself, can be taken as a standard by which to judge the average gold content of the entire area as reported by the examining engineer.

| Area A | | Area B | |
|--------|------------------|---------|---------------|
| 1..... | 130 × 40 = 5,200 | 9..... | 25 × 25 = 625 |
| 2..... | 35 × 30 = 1,050 | 10..... | 20 × 25 = 500 |
| 3..... | 60 × 20 = 1,200 | 11..... | 8 × 35 = 280 |
| 4..... | 50 × 20 = 1,000 | 12..... | 10 × 35 = 350 |
| 5..... | 40 × 20 = 800 | 13..... | 15 × 30 = 450 |
| 6..... | 50 × 30 = 1,500 | 14..... | 12 × 25 = 300 |
| 7..... | 160 × 20 = 3,200 | 15..... | 10 × 30 = 300 |
| 8..... | 42 × 30 = 1,260 | 16..... | 10 × 30 = 300 |
| | 210 | 17..... | 12 × 32 = 384 |
| | 15,210 | 18..... | 9 × 25 = 225 |
| | | | 292 |
| | | | 3714 |

Dividing 15,210 by 210 gives an average value of 72.42c. for area A, while for area B the division of 3714 by 292 gives 12.72c. If, however, the area as a whole is considered, the result is as below:

| | | |
|---------|-----|--------|
| A | 210 | 15,210 |
| B | 292 | 3,714 |

$$502 \text{ into } 18,924 = 37.69$$

That is, an average value for the whole of 37.69c. per cubic yard.

This question of the relation of the actual recovery from a small area to that of the average gold content of the entire area is one that should be thoroughly understood, not only by the examining engineers and the directors of a company handling dredging properties, but also by the investing public in general and by those who may be connected with any sort of an alluvial mine, for the question is the same whether applied to dredging, hydraulic mining, or elevating.

Tin Production in Cornwall

During February, yields from the principal mines were as follows:

| Mine. | Ore treated, tons. | Tin concentrate, tons. | Value. |
|--------------------|--------------------|------------------------|----------|
| Basset | 3,437 | 39 | \$18,500 |
| Carn Brea | 4,423 | 41 | 20,000 |
| Dolcoath | 9,033 | 114 | 54,000 |
| East Pool | 6,324 | 58 | 27,000 |
| South Crofty | 5,407 | 59 | 32,000 |
| St. Ives | *7,897 | 77 | 33,000 |
| Wheal Kitty | 1,214 | 17 | |

*Sixteen weeks run.

Cardiff, Wales, is the world's leading coal-shipping port. The coal output of Wales in 1913 was about 54,000,000 tons of which 26,340,012 tons of coal was shipped from Cardiff. Welsh coal is expensive to mine, the average being 220 to 230 tons per man per year. The average selling price last year was \$5 per ton.

Choice of Drum for Steam or Electrical Drive

By C. ANTONY ABLETT and H. M. LYONS

*The conditions governing the selection of the type of drum differ very considerably, according to whether the winder is to be driven electrically or by a steam engine, and it is, therefore, very desirable to discuss this question in a paper on electrical driving.

It is characteristic of the steam engine that its overload capacity is not very great and that the turning moment varies according to the position of the cranks.

which it will give, and, consequently, the motor for winding engines is usually selected with reference to the equivalent continuous load, and it is very rarely indeed that the starting moment or acceleration peak needs to be considered.

The first type of drum to be employed for winding engines was the cylindrical drum, but later the conical drum was introduced. In some cases the latter gives

FIG. 1 AND 2.

FIG. 3 AND 4.

For a two-cylinder engine with cranks at right angles, such as is usually used for a steam winder, the minimum turning moment is 0.785 of the mean turning moment, and the maximum turning moment is 1.112. The engine naturally must be able to start the hoist with the cranks in any position, so that the minimum turning moment must be at least sufficient to overcome the static load and friction.

Cylindrical and Conical Drums

An electric motor, on the contrary, has a very large overload capacity in proportion to the mean power

easier starting conditions and is beneficial to the steam engine, because the rope supporting the cage at the bank top is wound off the greatest diameter, while the rope attached to the loaded cage at the pit bottom is wound on to the least diameter, so that the empty cage partly balances the rope and the loaded cage at the start of the wind.

To illustrate the relative advantages of the cylindrical and the conical drum for the electrical or the steam drive at various speeds, Fig. 1 to 6, inclusive, have been worked out, while Fig. 7 is worked out for a seroll drum, and Fig. 8 for a Koepe pulley, under the same conditions as are illustrated in Fig. 3 and 4. These diagrams are worked out for the conditions listed following.

*From a paper on 'Electrical Driving of Winding Engines and Rolling Mills,' read before the Canadian Society of Civil Engineers and the Canadian Mining Institute.

| | |
|---|---------------------------|
| Net load | 9,000 lb. |
| Weight of empty cage and cars..... | 12,000 lb. |
| Depth | 1,600 ft. |
| Diameter of rope | 1½ in. |
| Diameter of rope sheaves..... | 16 ft. |
| Lead | 250 ft. approximately. |
| Cylindrical drum | 9-ft. diameter. |
| Conical drum | 9-ft. to 14-ft. diameter. |
| With cylindrical drum and empty cage at the bank, unbalanced load..... | 16,860 lb. |
| With conical drum and empty cage at the bank, unbalanced load..... | 10,000 lb. |

Fig. 1 and 2 are drawn for an output of 135 tons per hour. Fig. 1 represents the cylindrical drum where the maximum winding speed is 20 ft. per second. Fig. 2 represents the conical drum with an equivalent winding speed.

If the cylindrical drum in Fig. 1 is driven by a steam engine the horse-power equivalent to the starting torque would be 678, and this starting torque has to be developed in the worst position of the cranks. The horse-power equivalent to the corresponding average turning moment would be 865, which gives an ample speed of the engine would be 42 r.p.m. In the case of the conical drum the horse-power equivalent to the starting turning moment would be 350, and to the average turning moment 445. This horse-power, however, is not sufficient to provide for the acceleration turning moment, so that an engine having a maximum horse-power of 481 would be required, running at a maximum speed of 33 r.p.m. Thus, for the cylindrical drum, an 865-hp. engine running at 42 r.p.m. is required, and for the conical drum a 481-hp. engine at 33 r.p.m. is required, so that for the cylindrical drum an engine giving 20.6 brake horse-power per revolution is necessary, and for the conical drum, an engine giving 14.6. The use of the conical drum, therefore, demands a much smaller steam engine.

Motor Requirements

If the winder is driven electrically, a 378-hp. motor at 42 r.p.m. would be required with the cylindrical drum, and a 290-hp. motor at 33 r.p.m. for the conical drum. If the horse-power per revolution be worked out, it will be seen that these motors are of approximately the same size. In this case, therefore, it would be of advantage to employ a conical drum for a steam winder, but for the electrical winder, so far as capital cost is concerned, it would be distinctly disadvantageous, because there is no saving effected with the electrical plant and the winding engine with conical drums is considerably more expensive than that with cylindrical. The maximum power, however, taken from the supply system, is reduced nearly 30%. It should be remarked, however, that these two diagrams were worked out to show the advantages of the conical drum with a steam engine in this particular case, but for the electrical drive a diagram can be worked out with a cylindrical drum, to give the same output and to take a considerably smaller motor.

The diameter of the drum is usually fixed at not less than 60 times the diameter of the rope, so that, given the depth of the wind, the length of the drum, either cylindrical or conical, necessary to carry the rope is at once fixed. Where cylindrical drums are employed the travel of the two ropes on the drum can overlap (except in cases where the head sheaves are far apart, and the drum cannot be placed sufficiently far back), so that the cylindrical drum for two ropes is not very much longer than that required by the travel of one rope.

Conical Drums

Where conical drums are employed the minimum diameter cannot safely be reduced, and consequently the drum must be made with a larger average diameter, and although the length of drum occupied by each rope is actually less than with a cylindrical drum, yet the turns of the rope cannot lie close together, and a space of at least ¼ in. between each turn must be allowed. In addition, the cone paths for the two ropes must be quite distinct, as with conical drums the travel of the two ropes cannot overlap, and therefore the conical drum is much longer than the equivalent cylindrical drum. As, therefore, both the diameter and the length of a conical drum are greater than those of the equivalent cylindrical drum, its moment of inertia is much greater. In the case illustrated in Fig. 1 and 2, the moment of inertia of the conical drum is more than four times as great as that of the cylindrical drum, and as considerably more power is required to accelerate the conical drum, it may easily happen that all the advantage of the conical drum is lost for this reason.

Fig. 3 and 4 are worked out for an output of 270 tons per hour. Fig. 3 shows the case of the cylindrical drum where the maximum speed of winding is 40 ft. per second, and Fig. 4, that of the conical drum with an equivalent speed. An inspection will show that in these cases the size of the steam engine is determined by the turning moment corresponding to the acceleration peak. For the cylindrical drum a steam engine capable of giving 2035 hp. at 84 revolutions will be required, and for the conical drum a steam engine capable of giving 1690 hp. at 66 revolutions will be required, that is, a slightly larger steam engine will be required for the conical drum. It should be noted, however, that in the case of the cylindrical drum if constant acceleration is not assumed it would be possible to reduce the maximum horse-power of the steam engine from 2035 to 1950. Should the electrical drive be adopted, a 1090-hp. motor at 84 revolutions would be required for the cylindrical drum, and a 965-hp. motor at 66 revolutions for the conical drum, so that a larger motor is required for the conical drum.

In this particular case, if the Ward Leonard system is to be employed, the effect of using a conical drum would be to increase the size of the winding motor by 12%, but to decrease the size of the motor generator

set by 11½%, the net result of this being that the cost of the electrical equipment would be the same, and the cost of the winding engine would be greatly increased. The adoption of the conical drum would diminish the maximum acceleration peak by about 10%. If the Ilgner system is to be employed it will be found that the use of the conical drum enables a very slight reduction in the capacity of the flywheel to be made, but this reduction is so slight that there is no advantage in employing this drum, as it will only increase the capital cost of the winding engine.

If, however, the winding engine is to be driven by a three-phase motor the use of a conical drum would increase the motor in size by 12%. Consequently, the total cost of the winder is considerably increased, but, on the other hand, the average power wasted in the starter is reduced from 325 to 260 hp., which means that a saving of 65 hp. minutes per wind is effected.

FIG. 5 AND 6.

Taking the cost of power at 1c. per kilowatt hour, this represents a saving of 65c. per hour, or about \$2000 per year.

Fig. 5 and 6 are worked out for an output of 337.5 tons per hour. Fig. 5 shows the case of a cylindrical drum where the maximum winding speed is 50 ft. per second, while Fig. 6 shows the case of a conical drum with an equivalent winding speed. It is easily seen that if a steam engine is used to drive this winder, a larger engine will be required for the conical drum than for the cylindrical. In the case of the electrical

drive a 1490 hp. motor at a maximum speed of 105 revolutions would be required with the cylindrical drum, and 1390-hp. motor at a maximum speed of 83 revolutions for the conical drum. It will thus be seen that if the Ward Leonard system is used the effect of the conical drum will be to increase the size of the winding motor by 18%, and to reduce the size of the converted set by about 7%, so that with the Ward Leonard system or the Ilgner system it is a distinct disadvantage to use a conical drum for this high-speed winder. If a three-phase motor were used to drive this winder the provision of a conical drum would increase the size of the motor 18%, but would reduce the average power lost in the starter from 620 to 566 horsepower.

Cylindro-Conical or Scroll Drum

The cylindro-conical drum is a drum which has a cylindrical portion of large diameter at the middle of its length. At each end of this large cylinder there is a short cone reducing the diameter of the drum, and the remainder of the drum at each end consists of a short cylindrical portion of small diameter. In commencing a wind the rope hoisting the loaded cage from the bottom of the pit is wound upon one of the small cylindrical portions, while the rope lowering the empty cage is wound off the large cylindrical portion. Such winders are usually proportioned so that the drum reaches full speed while the rope from the loaded cage is still being wound on the smallest diameter, but at this point the loaded cage has not reached full speed, although the empty cage has, and the loaded cage does not reach full speed until the rope has reached the top of the cone. The greater portion of the run is made with the ropes on the large diameter. Toward the end of the run the rope lowering the empty cage runs down the cone at the other end of the drum, decelerating the cage, and when this rope has reached the small diameter cylinder, the drum is then decelerated.

It will be seen that on the large diameter cylindrical portion of the drum the travel of the two ropes can overlap, and they are always designed to do so, unless the head sheaves are too far apart to permit of this.

The possibility of overlapping the travel of the ropes with a scroll drum enables a scroll drum to be constructed of shorter length than the corresponding conical drum, and it may easily be even shorter than the corresponding cylindrical drum. It will be found also that the moment of inertia of a scroll drum is less than that of the corresponding conical drum, but greater than that of the cylindrical drum, and in the case illustrated in Fig. 7 the stored energy of the scroll drum is about two-thirds that of the conical drum illustrated in Fig. 4, which produces a marked reduction in the acceleration peak.

Fig. 7 is a power diagram for a winder provided with a cylindro-conical drum worked under the same conditions as those assumed in working out Fig. 3 and 4. In the case illustrated, the small cylindrical portions at each end of the scroll drum are 9 ft. in diameter

and each carry six turns of the rope. The conical or scroll portions increase in diameter from 9 ft. to 13 ft., and each carry five turns of rope. The large cylindrical portion is 13 ft. in diameter and carries 31 turns of rope.

In Fig. 7, line AB represents the constant acceleration of the drum, the descending cage and rope to full speed, and the part acceleration of the ascending cage and rope, while this latter rope is being wound upon one small cylindrical portion of the drum. The line BC shows the drop in power corresponding to the completion of the acceleration of the drum and the descending cage. The line CD shows the continuation of the acceleration of the ascending cage and rope as this rope is being wound on one of the scroll portions of the drum. The line DE shows the fall in power at the completion of the acceleration of the ascending cage and rope. The line EF shows the power taken by the full speed run of both cages, and this power gradually decreases as the descending rope lengthens and the ascending rope shortens, so that the descending rope gradually balances a greater portion of the ascending load. The line FG shows the decrease in power, corresponding to the deceleration of the empty cage, as its rope commences to run down the scroll. The line GH shows the gradual increase in power as the rope to the empty cage runs down the scroll, and therefore balances the ascending load to a less extent. The line HI shows the fall in power at the commencement of the deceleration of the drum, the ascending cage and the rope and the line IJ shows the gradual fall in power during the deceleration period.

In this case it will be noticed that power is taken by the winding motor during the deceleration period, and this is not a case where electrical braking is necessary. If a steam engine were used to drive this scroll drum winder, an engine capable of giving 1465 hp. at a maximum speed of 62.7 revolutions will be required, and this is a smaller engine than would be required for the conical drum of Fig. 4, and slightly smaller than that required for the cylindrical drum in Fig. 3. If this winder is driven electrically, a 780-hp. motor at 62.7 revolutions would be required, and this is a smaller motor than would be required for the conical drum winder of Fig. 4, or the cylindrical drum winder of Fig. 3, the latter being about 4% smaller than that required for the cylindrical drum winder. If this winder is driven on the Ward Leonard system, the size of the motor generator set can be reduced by 30%, and if it is driven on the Ilgner system, the same reduction can be made in the motor generator set, and the weight of the flywheel can be reduced about 13 per cent.

The capital cost of the mechanical parts of the scroll drum winder is, of course, more than the cost of that for a cylindrical winder, but it is not so great as that of the mechanical parts of a conical drum winder, and if this winder is to be driven on either the Ward Leonard or the Ilgner system, it is probable that the

scroll drum winder represents one of the cheapest combinations in capital cost that can be put in to do the work. Should this winder be driven on the Ward Leonard system, it should be pointed out that the maximum peak in power which it requires is 25% less than that required with the cylindrical drum winder. If a three-phase motor is used for driving this winder, the size of the motor is slightly less than that which would be required for the cylindrical drum winder, but the waste of power is very much less, the average waste being 170 hp. continuously as compared with 260 hp. for the conical drum winder, and 325 hp. for the cylindrical drum winder.

Koepe Pulley Winder

This type of winder is used to a considerable extent in Europe, particularly in Germany. It differs from any other type, as the rope is not wound upon and off drums, but is carried over the pulley and makes contact with it for less than a single turn. Thus the rope

FIG. 7.

from the ascending cage comes up the shaft over the driving pulley of the winder, and then down to the descending cage, being suitably guided by head sheaves. It will thus be seen that the winding rope is driven by friction alone, and, consequently, there must be a very definite limit between the pull in the ascending rope and the pull of the descending rope, otherwise the rope will slip on the pulley, and, to keep the difference in pull of the two sides of the rope as small as possible, a balance rope is always necessary. It should be noted that such a winder cannot work with a very high acceleration, otherwise slipping of the rope will take place. As the rope is bound to creep on the pulley to a certain extent, the depth indicator must frequently be reset to insure its accuracy.

As with a Koepe pulley winder the axial length of the pulley is very short indeed compared with that of

a drum on which the rope has to be wound, and as the weight of the winding drum is not increased by the rope which it is carrying, the moment of inertia of the revolving parts of a Koepe pulley winder is small, and this, together with the use of the balance rope, keeps the maximum acceleration peak comparatively small compared with that of other types of winder.

For purposes of comparison, Fig. 8 has been drawn for an output of 270 tons per hour, and may be compared with Fig. 3 showing a cylindrical drum, Fig. 4 showing a conical drum, and Fig. 7 showing a scroll drum. In this case, however, the time of acceleration has had to be increased from 12 to 22 seconds, so that the acceleration should not be so great as to cause the rope to slip on the drum, and to enable the output to be obtained with this slower acceleration the maximum speed has had to be increased from 40 to 46 ft. per second. In European practice the diameter of a Koepe pulley is usually taken as 100 times that of the rope, but for purposes of comparison with the other cases, a 9-ft. pulley has been considered, which is 66 times the diameter of the rope.

A 935-hp. motor running at maximum speed of 97

1276 hp., or over 30% less than the maximum horsepower in the case of a cylindrical drum winder, it will, if driven on the Ward Leonard system, have the least severe demand on the source of electrical supply. If the winder should be driven by a three-phase motor, it will be seen that while the small moment of inertia of the moving parts keeps down the acceleration peak and so tends to decrease the waste of power in the controlling resistances, the fact that a long time of acceleration has to be allowed may increase these losses. In the present case, losses in the controlling resistance correspond to a continuous loss of 241 hp., as compared with 325 in the case of a three-phase motor driving a cylindrical drum winder, and 170 in the case of a three-phase motor driving the scroll winder.

Generally speaking, the Koepe pulley winder shows to the greatest advantage with deep shafts, as it avoids the use of excessively long drums, and, from the electrical point of view, where the winding speed is not very high and where the acceleration period is short compared with the total time of winding. It has the disadvantage that if the rope breaks, both cages are detached from the winder.

General Conclusions Concerning Winding

Generally speaking, we are of opinion that the Ward Leonard or Ilgner system of electric winding is the most suitable for vertical shafts, and for all cases where large outputs are required and short and frequent winds are made.

The three-phase winder always has the disadvantage that it cannot be so completely protected against careless handling as either the Ward Leonard or the Ilgner, but it may prove more economical for long slopes where the full speed run is a long one and the periods of acceleration are comparatively infrequent.

Regarding the choice of drums for the winding engine, we are of opinion that in many cases where electrical drive is adopted, the cylindrical drum winder will prove the most suitable, but that in cases of deep shafts where the winding speed is high the scroll drum winder may prove better than the cylindrical drum winder, but that the field of application of the conical drum winder to electric winding is very small.

FIG. 8.

revolutions will be suitable for driving this winder, and comparing this with the motor required for the cylindrical drum in Fig. 3, it will be seen that the Koepe pulley winder can be driven with a 25% smaller motor. If it should be driven by the Ward Leonard system, the motor generator set would be 14% smaller, and if it should be driven on the Ilgner system, the motor generator set will be similarly reduced, and the weight of the flywheel can be reduced about 12 per cent.

As the cost of the mechanical parts of the Koepe pulley winder is not great, this will be the cheapest form of winder for doing the work, and as the maximum power required at the end of the acceleration period is

TABLE SHOWING THE INFLUENCE OF THE DIFFERENT TYPES OF DRUMS ON THE ELECTRICALLY DRIVEN WINDING ENGINE

| Depth, 1600 ft. | Output, 270 tons per hr. | | | |
|--|--------------------------|---------------|--------------|---------------|
| | Cylindrical drum. | Conical drum. | Scroll drum. | Koepe pulley. |
| Power of motor..... | 1,090 | 965 | 780 | 935 |
| Speed of motor..... | 84 | 66 | 62.7 | 97 |
| Horse-power per revolution | 13 | 14.6 | 12.4 | 9.6 |
| Maximum peak with Ward Leonard system | 1,865 | 1,690 | 1,390 | 1,276 |
| Average loss of power with three-phase system hp.... | 325 | 260 | 170 | 341 |

Silver produced by the Nipissing mine to the first of the year totals 32,585,418 oz. or 1117 short tons. Ore reserves are estimated to contain 9,510,000 ounces.

Salt Lake Meeting of the American Institute of Mining Engineers

The 108th meeting of the Institute will be held at Salt Lake City, Utah, on August 10 to 14, inclusive. Although the Institute has visited Salt Lake City at various times en route to other meetings, this is the first time in its history that a meeting has been devoted exclusively to Utah. In July 1887 the members convened at Salt Lake City and then adjourned to Butte, Montana, but the technical and social attractions of Salt Lake City and vicinity more than warrant the holding of a meeting exclusively in this place.

Local committees have been formed under the chairmanship of R. C. Gemmell, and are already actively engaged in preparing for the entertainment and convenience of visiting members. Charles W. Goodale, chairman of the committee on precious and base metals, is in close touch with the local committees, both by mail and personal conference, and the progress already made by the committee on precious and base metals assures an interesting technical program.

Twenty-five papers are already in the hands of the secretary and have been accepted for this meeting by the committee on papers and publications. The attention of authors, members of committees, and members of the Institute is called to the necessity of having all papers in the hands of the secretary of the Institute before May 31.

The social features of the Salt Lake meeting will include many visits to neighboring mines and metallurgical works, and it is expected that invitations will be general. Among the several points of interest which might be mentioned are: Bingham cañon, where is situated the open-pit mine of the Utah Copper company, at which some of the most interesting mining operations of the world are carried on; also the methods of underground mining at the Ohio Copper Co. and other well known mines, such as the Highland Boy, Utah Apex, Bingham & New Haven, and others. An interesting aerial tramway is in operation from the Utah Consolidated Copper Co. to the Tooele smelter. This lead and copper smelter is the latest one built, and, since it embodies many novel features, it will doubtless be exceedingly interesting to all. Garfield is the site of the Arthur and Magna mills of the Utah Copper Co.; the copper smelter of the American Smelting & Refining Co., and an industrial town owned by the Utah and Garfield companies. At Lark is situated the mill of the Ohio Copper Co.; and at Murray is the lead smelter of the American Smelting & Refining Co. Midvale is the site of the United States Smelting, Refining & Mining Co., where may be seen the Sprague process for collecting fume, a plant for arsenical recovery, and the Huff electrostatic process, which will be novel to many of the members. Park City is a famous old camp of Utah, where are the mines of the Silver King Coalition, Silver King Consolidated, Ontario, Daly-Judge, Daly West, and others.

The Holt process for the hydro-metallurgical treatment of low-grade ores is an interesting innovation. Tintic contains several mines producing silicious ores, showing a little copper and a good deal of silver, such as the Centennial Eureka, the old Eureka Hill, Gemini, Eagle & Blue Bell, Grand Central, Mammoth, and others. Many other interesting points, at a slightly greater distance from Salt Lake City than those mentioned, will doubtless attract several members, and it is certain that the technical features will be more than sufficient to attract many members to this meeting.

Metal Production of Central States in 1913

Silver, copper, lead, and zinc produced in the central states, according to the final figures of J. P. Dunlop, of the U. S. Geological Survey, were valued at \$58,045,927. Of this, Missouri and Michigan contributed by far the largest amount, the Missouri production being valued at \$29,604,890, and that of Michigan at \$21,235,561. These figures show a marked decrease compared to 1912, the total for the central states in that year being \$79,675,814.

Silver, lead, and zinc produced at mines in Oklahoma were valued at \$1,855,217, compared with \$1,101,042 in 1912. The increased yield of lead and zinc in 1913 was due entirely to operations in the Miami field. Drilling operations were conducted over a wide area and resulted in finding some extensive bodies of mineralized ground, the sinking of new shafts, and the erection of concentrating plants.

Silver, lead, and zinc produced at mines in Illinois were valued at \$336,963. This is less than half the value of the production for 1912, which was \$679,259. Development work was, however, more active than in previous years, so that the outlook is stated to be better for 1914.

The value of the mine output of lead and zinc in Wisconsin was \$3,570,464. These figures show a decrease of \$1,222,726 compared with 1912, when the value was \$4,793,190.

Petroleum Production in 1913

According to C. du Poizat, in *Echo des Mines*, the principal countries of the world yielded the following tonnage of oil:

| | 1913. | 1912. |
|-------------------------------|------------|------------|
| United States | 32,000,000 | 29,500,000 |
| Russia | 9,000,000 | 9,500,000 |
| Mexico | 2,000,000 | 2,300,000 |
| Rumania | 1,800,000 | 1,800,000 |
| British and Dutch Indies..... | 1,700,000 | 1,700,000 |
| Galicia | 1,000,000 | 1,700,000 |

Slime scraped from the Standard Consolidated company's ponds, at Bodie, California, in 1913, totaled 10,151 tons worth \$5.43 per ton. The cost of collecting was 58.1c. per ton.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Drilling at Pato

The Editor:

Sir—Articles of much interest concerning the work of the Pato Mines, Ltd., in Colombia, have appeared in your paper from time to time, and in some of these articles the discrepancy between the drilling results and the dredge returns have been mentioned. In some of your news items it has been stated that the Pato company has been drilling their San Francisco property with Empire drills, all of which is true. However, a number of people have coupled up these statements and assumed that the earlier drilling of the Pato ground was done with Empire drills, whereas the truth of the matter is that it was done with steam drills. I have had many inquiries of late about this so-called drilling inaccuracy, wherein the parties have wrongly blamed the Empire drill for this discrepancy.

In justice to my Company, the New York Engineering Co., and the Empire drill, which is manufactured by it, I would be glad to have you publish the following fact: The original drilling of the Pato property was done by A. P. Rogers and C. H. Munro, with steam drills, some six or seven years ago, and before the Empire drill was known. It is in this work that the results have been criticised and not the subsequent drilling done with Empire drills.

A. C. LUDLUM.

New York City, April 4.

The Radium Bill

The Editor:

Sir—In your editorial of April 11 concerning the proposed radium bill you state your inability to see why the mining men of Colorado should object to it, or why its provisions should work hardship to those concerned. If you will permit, I should like to explain the reasons that seem to me, and to many others with whom I have talked, sufficient for opposing it. The fact that the Government retains a perpetual option on the ores extracted will effectually discourage prospecting, investing in prospects and developing them, and working out new processes for the reduction of the ores. In other words, it will nip in the bud what bids fair to become a flourishing branch of the none too flourishing metal-mining industry of this state. Several of the contributors to your recent symposium on prospecting mentioned the discouraging effects of governmental restrictions on the location of claims. If those now in force are discouraging—and no one familiar with the prospec-

tor can doubt it—this new one will be practically prohibitive. The owner of a radium claim cannot enter into a contract with anyone except the Government to sell his ore. Without a contract covering a reasonably long period, he is at the mercy of the fluctuations of the market and cannot tell whether or not he is conducting his mining operations at a profit at any given time. The metallurgist will have no incentive to invent or improve reduction processes, because, even if he owns a producing mine, he has no means of assuring himself of a steady supply of ore.

Without pernicious government interference it is not unlikely that, in the course of the next few years, new discoveries of deposits and processes would make radium comparatively cheap and plentiful, as has been the case with other rare metals. This is greatly to be desired, but the proposed bill will certainly retard, if it does not entirely prevent this. It will tend to throw the entire burden of prospecting, development, mining, and treatment on the Government. While the government bureaus do careful and thorough scientific work, they are notoriously slow in accomplishing practical results and there is no reason to believe that they would speed up in the present case. On the contrary, it is almost certain to take them longer and to cost the people of the United States more to produce a given quantity of radium than if they bought it in the open market and allowed everyone a free hand in its production. If Congress and the interested government officials are sincere in their desire to obtain the greatest possible amount of radium in the shortest possible time, and are not merely anxious to create a few more jobs and to strengthen their bureaus, why do they not accept Mr. Flannery's offer to deliver them 200 grams of radium in the course of the next five years at a maximum price of \$80,000 per gram? They certainly cannot get it any more quickly and probably cannot produce it more cheaply than that. In closing, I wish to state that I have no personal interest in the radium mining or reduction business.

HORACE F. LUNT.

Colorado Springs, Colo., April 15.

What Is the Matter With Prospecting?

The Editor:

Sir—There are many causes that have had their influence in the restriction of the development of prospects. There is no question but that many of the more prominent exposed croppings have been discovered. The action of the Land Office during several past administrations (the present appears to approve a more liberal policy) has discouraged the man with capital; Pinchot's conservation views, the course pursued by many eastern magazines and papers in continually advising the public that all mining investments are extra hazardous; the fact that the majority of the miners today are foreigners who work and send their money to the old country, together with the world-wide un-

favorable financial conditions, have operated to make it impossible for the promotor of a mining property, doing a legitimate business, to sell stock. But the average mining engineer is more to blame than all others for keeping capital from the development of prospects. For years he has been writing and talking of 'ore blocked out, ore in sight' until you can interest very few. Nor will they even listen to anything that has not ore blocked on three to six sides.

The engineer, from his training, experience, and observation has been concerned with developed properties. He has not had experience with prospects, and when sent to examine one, he invariably turns it down. He figures this is safer, but really from lack of experience and knowledge, he rarely is qualified to pass on its merits.

In twenty-five years experience, from Alaska to old Mexico, I have known but two mining engineers whose judgment on a prospect was worth consideration. I have known several fortunes lost, to the original owners, by mining engineers turning down prospects that later proved good properties. Not but what the technical education is all right, and makes the better man, provided he will get into the harness and acquire by experience the necessary practical knowledge; but the facts are that nine times out of ten the technical course spoils the man for manual labor.

Many have been driven into other lines of business, possibly where they belong, at least until such a time as they learn that all mines were once prospects, and can give any old mine, prospect, mine, or man a square deal. That's all that is needed, a square deal, in order to rejuvenate mining.

G. L. SHELDON.

Ely, Nevada, April 2.

The Rand Banket

The Editor:

Sir: I have pleasure in responding to your invitation to contribute to the discussion of C. B. Horwood's paper on 'The Rand Banket.' As, however, my detailed mapping of the Witwatersrand in connection with the Geological Survey is approaching completion, it will be necessary for me before long to deal with the whole subject fully, and it is therefore not my intention to discuss Mr. Horwood's paper at any length. Lest, however, absence of comment should appear to indicate that Mr. Horwood's views on several points are accepted by others acquainted with the area of which he writes, it is perhaps desirable to briefly refer to one or two of them at the present time.

On the question of the origin of the Witwatersrand gold, Mr. Horwood having taken up the position of a strong advocate of the infiltration theory, naturally passes over much of the evidence for the opposing views. The arguments for the placer origin of the gold have been most recently stated by J. W. Gregory and should be carefully considered by anyone wishing

to arrive at independent conclusions on the question. Although commencing my survey of the district with inclinations, if anything, in favor of the infiltration theory, my four years' study of the Rand, including repeated investigations of the 'reef' at numerous points over the greater portion of its extent, have not furnished any evidence in favor of that view. On the contrary, I have met with much evidence in favor of a placer origin, in addition to that already brought forward by the advocates of that view.

Those who compare the evidence in favor of the two will doubtless note that while the arguments in favor of the placer theory are for the most part of a very simple and direct character, based upon direct observation of and comparison with other similar deposits about whose origin there can be no doubt, those in favor of the infiltration theory are very frequently highly speculative or theoretical, as will be apparent from the references quoted by Mr. Horwood.

That there has been considerable local re-distribution of the gold content of the reefs, no one well acquainted with them will be inclined to doubt, and in many cases this re-distribution has naturally produced effects which although purely secondary are suggestive of an infiltration origin for the whole deposit. The local character of some of these effects is, however, strikingly shown in many instances.

With regard to the influence of dikes—against the few examples of such intrusions being associated with specially rich portions of the gold-bearing beds cited by Mr. Horwood, must be set the dozens of examples in which either entirely opposite conditions are found or where nothing unusual is to be noticed. Although it is a point to which I have paid special attention on visiting a large number of mines, I have not yet met with any instance in which the presence of richer 'reef' was clearly dependent on the intrusion of a dike except as a purely secondary and extremely local result. I have, however, met with several instances where the accidental disposition of a dike with regard to a rich patch of reef has at first sight suggested a causal relationship. Further examination, however, has never confirmed this view.

Students of Rand geology will be grateful to Mr. Horwood for the many excellent photographs of Rand specimens which have been reproduced, and also for the publication of the detailed analyses he has had made in connection with the occurrence of carbon and of iridosmine in the banket, although in the case of both these latter the deductions drawn by many readers from the results may be opposed to the interpretation placed upon them in the paper.

E. T. MELLOR.

Johannesburg, Transvaal, March 25.

The Anaconda Copper Co. reports that the year ended December 31 shows a total revenue of \$61,258,755, which is a decrease of \$6,003,285. The balance for dividends was \$11,323,500, a decrease of \$4,532,835.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Sulphuric acid manufactured by the Wallaroo and Moonta company, South Australia, in 1913, amounted to 5602 tons, at a cost of \$4.58 per ton.

Residue from the high-grade mill of the Nipissing Mining Co., at Cobalt, contained last year 20 to 40 oz. silver per ton, 8 to 10% cobalt, 4 to 6% nickel, and 30 to 40% arsenic. This is sold to manufacturers of cobalt products, and 1659 tons were sold netting \$62,484. This mill treated 1200 tons of Nipissing ore averaging 2501 oz., and 632 tons of custom ore assaying 2854 oz. silver per ton.

Beri-beri is a disease contracted in the tropics, mainly through eating polished rice. It is characterized by symptoms referable to the gastro-intestinal, cardiac, and nervous systems. Dropsy, heart weakness, or paralysis, or a combination of all these symptoms, may be present, and if not fatal it disables its victims, and renders them unfit for work. The Bureau of Science, at Manila, Philippine Islands, has been investigating this ailment, and in *Press Bulletin* No. 24 are given details of the work being done.

Mine accounting varies greatly on different properties, and in many parts of the world. According to A. E. Jacobs, in the February Monthly *Journal* of the Chamber of Mines of Western Australia, a consideration of this important branch of the mining business leads to the conclusion, that it largely resolves itself into the question of being able to record with accuracy and reasonable despatch, the cost of the various operations arising out of the daily working of a mine. The paper by this writer, 'The Accounts of a Mine,' is 16 pages long, and with the discussion on account books, cost segregation tables, and other data, is worth filing.

Consumption of supplies at the Nipissing low-grade mill in 1913, when 77,240 tons of ore averaging 27.18 oz. silver per ton was treated, with 91.85% extraction, was as follows:

| | Pounds. | Pounds per ton. | Cost per pound. | Total cost per ton ore. |
|------------------------|-----------|-----------------|-----------------|-------------------------|
| Cyanide | 400,722 | 5.190 | \$0.1500 | \$0.7785 |
| Caustic soda | 246,880 | 3.200 | 0.0214 | 0.0684 |
| Lime | 512,595 | 6.640 | 0.0040 | 0.0266 |
| Aluminum dust | 43,911 | 0.568 | 0.3373 | 0.1917 |
| Aluminum plates | 20,731 | 0.268 | 0.2438 | 0.0654 |
| Aluminum ingots ... | 74,483 | 0.964 | 0.2207 | 0.2128 |
| Flint pebbles | 505,170 | 6.540 | 0.0098 | 0.0646 |
| Ore pebbles | 239,500 | 3.100 | | |
| Coal for heating | 2,329,250 | 30.160 | 0.0029 | 0.0881 |
| Power, kilowatt-hours | 3,983,000 | 51.570 | 0.0115 | 0.5933 |
| Total | | | | \$2.0894 |

Costs of mining and treatment at the Perseverance mine, Kalgoorlie, during 1913, were as follows:

| Mining: | Cost per ton. |
|--|---------------|
| Wages and contracts | \$0.86 |
| Explosives | 0.16 |
| Timber | 0.02 |
| Drill parts and air lines | 0.03 |
| Candles | 0.02 |
| Steel and tool sharpening | 0.03 |
| Stores, etc. | 0.02 |
| Air for drilling | 0.10 |
| Power for hoisting | 0.25 |
| Assaying, surveying, sampling | 0.04 |
| General maintenance | 0.10 |
| Supervision | 0.02 |
| Net debit charges on development | 0.02 |
| Total mining | \$1.67 |
| Milling: | |
| Jaw crusher | \$0.10 |
| Ball-mills | 0.49 |
| Roasting furnaces | 0.68 |
| Grinding pans | |
| Mechanical agitators | 0.51 |
| Filter-presses | 0.41 |
| Precipitation, etc. | 0.10 |
| Disposal of residue | 0.11 |
| Total milling | \$2.40 |

The accompanying halftone shows the Marysville Buttes of Sutter county, California. The Marysville folio of the U. S. Geological Survey covers portions of Butte, Yuba, Sutter and Colusa counties. In the main, this area consists of broad alluvial plains, suited for agriculture. The Feather and Yuba rivers contain

MARYSVILLE BUTTES, CALIFORNIA.

profitable gravel for dredging. In pronounced contrast to the monotonous plains and low rolling hills, there rise, in the centre of the area, between the two principal rivers, the Marysville Buttes. The central peaks attain an elevation of 2000 ft. They are a circular group of mountains, 10 miles in diameter. Oaks, pine, and brush grow on them. Snow hardly ever falls, the temperature ranging between 18 and 115°. The rainfall is 18 in. per year. In general, it may be said that the Buttes are an extinct volcano of Neocene age, the internal structure laid bare to some extent by erosion. There are three divisions to the Buttes, topographically and geologically distinct, namely (1) the peripheral tuff ring; (2) the interior ring of up-turned sedimentaries; and (3) the central core of igneous rocks. The latter are massive volcanic rocks, mixed with breccias of the same material. The Marysville Buttes attract a great deal of attention to mining men traveling north through California.

Special Correspondence

JUNEAU, ALASKA

FUTURE OF THIS LOW-GRADE DISTRICT.—THE TREADWELL GROUP, ALASKA GASTINEAU, ALASKA JUNEAU, AND EBNER MINES.—HYDRO-ELECTRIC POWER.

Within the next five years, it is safe to say that the district around Juneau, along the Gastineau channel, will be the centre of some of the largest low-grade gold producers in the world. Developments point to that end. As is well known, the group of mines on Douglas island, opposite Juneau, have been highly profitable for many years, and are treating an aggregate of 1,566,000 tons of ore averaging \$2.50 per ton, and paying \$1,594,460 (\$1 per ton) in dividends per year. The Perseverance and Sheep Creek mines, on the mainland, operated by the Alaska Gastineau Mining Co., which is controlled by the Alaska Gold Mines Co., has developed an immense tonnage of \$1.50 ore. Records of the work done have been published in this journal from time to time, the preparatory work being described by Grant H. Tod in the issue of August 2, 1913. A mill with an ultimate capacity of 20,000 tons per day is being constructed. The accompanying halftone shows a panorama of the property of the Alaska Juneau Gold Mining Co., and the present stage of work is seen at a glance. The plans of the Company were described by F. W. Bradley in the *Mining and Scientific Press* of December 6, 1913. Eventually an output of 12,000 tons of \$1.45 ore per day is to be treated. The total cost will be about 80c. per ton. The ores from both of these large mines at Juneau is to be handled through long adits, which makes lower haulage charges. The system of mining will be somewhat different from that in the mines on Douglas island, and it is estimated will be 48c. per ton lower than the latter. There is an abundance of timber for all purposes, and water for electric power generation sufficient for present purposes. In the future, as a larger output of electricity is required, it will be necessary to bring power in from outside. Projects for the 'Long Lake Power Development' were described by E. P. Kennedy; and the 'Speel River Electro-chemical Project,' by W. P. Lass, in the issues of January 24 and 31, 1914, respectively.

The third of the great properties now being developed at Juneau is the Ebner, adjoining the Alaska Juneau mine to the north. It is now announced that the United States Smelting, Refining & Mining Co. paid \$225,000 for the Ebner property at auction, in addition to private purchase of bonds, making the total investment more than \$500,000. The Company also has options on about six miles of adjoining properties, and on water-power privileges now controlled by the Dora Construction Co. and in which the Company can secure a 51% interest by paying the \$300,000 said to have been expended on development. A deep-level adit to cross-cut the orebody is now in progress.

The annual report of the Alaska Gold Mines Co., mentioned above, for 1913, has just been made public. Of the Alaska Gastineau Mining Co.'s bond issue of \$3,500,000, and stock of \$12,000,000, it owns \$3,267,500 and \$11,299,845, par value, respectively. No. 1 shaft was sunk to a depth of 1544 ft. Development on the vein, in preparation for mining, was continued on most of the proposed levels above No. 10 level, this having been extended a total length along the vein of nearly 5000 ft. The height of the vein, measured on its dip above the Sheep Creek adit, and for the length of the zone developed on No. 10 level, is nearly 2000 ft. Ore in this area would be over 50,000,000 tons. A new \$1.60 orebody is being opened north of the main Perseverance vein. By January 1, 1915, the first unit of the 6000-ton mill should be in operation.

PANORAMA OF THE ALASKA JUNEAU GOLD MINING CO.'S PROPERTY ON GASTINEAU CHANNEL, JUNEAU, ALASKA. DOUGLAS ISLAND ON THE RIGHT.

WASHINGTON, D. C.

RADIUM BILL SIDETRACKED.—NEW BILL FOR EXPLORATION OF PHOSPHATES, ETC.—MINING LAW BILL.—WATER-POWER BILL. LEASING WITHDRAWN MINERAL LANDS.

On May 1, Senator Walsh tried to have his Radium bill made the unfinished business of the Senate, after it had acted on the Grain Inspection bill, but it was easily sidetracked for the Panama Canal Tolls repeal bill. Congress has ceased to take any great interest in the Radium bill.

The bill of great indirect interest to the mining world, authorizing exploration for and the disposition of coal, phosphate, oil, gas, potash, or soda has been agreed upon in the full committee on public lands of the House, and it will be reported next week with a favorable recommendation. The bill is fathered by Congressman Ferris, of Oklahoma, chairman of the committee, and there were only two negative votes against it in the committee. These were by Congressmen Taylor of Colorado and Johnson of Utah. It is a leasing bill, and its character is well illustrated by the section relating to phosphates, which states that the Secretary of the Interior is authorized to lease deposits of phosphates or phosphate rock, belonging to the United States, under conditions specified in the law and through advertisement and competitive bidding. In the general provisions it is declared that no person, association, or corporation, except as otherwise provided, shall hold more than one lease, directly or indirectly, and that no person, association, or corporation holding a lease under the provision of this act shall hold more than a tenth interest, direct or indirect, in any agency, corporate or otherwise, engaged in the resale of coal, phosphate, oil, gas, potassium, or sodium purchased from such lessee; and any violation of the provisions of this section or of the anti-trust laws of the United States shall be ground for the forfeiture of the lease or interest so held. No lease can be sublet except by consent of the Secretary of the Interior, or assigned.

The mines committee of the House has made arrangements to report favorably, next week, the bill for the establishment of experimental mining stations in the metalliferous states. No action has so far taken place in any way on the bill creating a commission to codify the mining laws of the United States. It is still waiting for its opportunity.

A bill of interest to mining men is the Ferris bill, now with the House Committee on Public Lands, respecting the control of water power on the public domain. Hearings are largely attended. It provides for the development of water power and the use of the public lands in relation to electric power. Among those heard this week was W. L. Fisher, formerly Secretary of the Interior, who favored the bill, saying that state rights would be adequately conserved in the bill, but that the final control and ultimate supervision of power must rest in the Federal Government, and not in some state which could not take a broad and disinterested view.

Senator Walsh of Montana has introduced a new bill for the leasing of oil and gas lands withdrawn from entry. The bill is a short one and is interesting as another sample of desired legislation. It provides that, within six months from the passage of the act, any locator or his successors to any claim to unpatented oil and gas lands included in an order for withdrawal, upon which oil or gas has been discovered, or was being produced or operated on by drilling on January 1, 1914, and the claim of which was initiated prior to July 3, 1910, may have leased to him by the Secretary of the Interior the lands so relinquished. These must not exceed a maximum of 2560 acres. The leases to be conditioned upon payment by the lessee of a royalty of not exceeding one-eighth of the oil or gas extracted, each lease to be for 20 years, with the preferential right for a renewal

for 10 years upon such terms as the Secretary of the Interior may lay down.

NEW YORK

UNITED STATES STEEL CORPORATION'S REPORT AND BUSINESS CONDITIONS.—LEACHING AND FLOTATION OF COPPER ORES.—UTAH COPPER DIRECTORS.—MINING IN MEXICO.

The quarterly report of the United States Steel Corporation is of great interest as an index of general business, and the one which has just been published is decidedly discouraging. After the first of the new year everyone had hoped that business was going to improve, and the money market indeed, for a time, seemed to reflect better business conditions. In so far as the Steel Corporation can be taken as representative of industrial conditions over the country as a whole, it is decidedly pessimistic. The earnings for the quarter ended April 1 were less than \$18,000,000, or about \$5,000,000 less than the preceding quarter, and not much more than half of the earnings for the same period a year ago. This leaves only about \$65,000, after the dividend on the preferred stock is paid, to meet the \$6,350,000 required for the 1¼% dividend on the common. This makes a total deficit of something like \$7,300,000 for the past six months. It has been the hope all along that business would pick up materially by the beginning of summer at least, but the outlook now seems discouraging. The Democratic administration, according to some of the statements given out last year, seems to think that business men may conspire to depress business in order to put the administration in a hole. Supposing such an idea were possible, the conspiracy seems to be a pretty general one. So much has been said about the bad situation of the railroads that everyone is familiar with it. The domestic copper market has been dull, and were it not that sales to Europe have continued large, the copper market here would be quite depressed. The lead market is quiet, evidently reflecting the unsatisfactory conditions of general business among the consumers of lead. There does not seem to be any immediate sign of a marked revival of business, though that is what everyone is hoping for.

Among the items classed as important is the statement that the Utah Copper Co. is about to build a 10,000-ton leaching plant, and that work on a 2000-ton unit will be started within a few months. It will consist of coarse crushing, leaching with sulphuric acid, and precipitation of copper on iron. The flotation process will be used only on low-grade concentrate from the mills now working. Most of the copper companies, however, are now pursuing rather a policy of 'watchful waiting,' since such important large-scale experiments are being carried on by the Anaconda Copper Co., and the work of others will be greatly facilitated when the results of the work there become known. The Phelps-Dodge organization is pushing its work with a great deal of vigor, and has recently secured the services of Lawrence Addicks, formerly superintendent of the United States Metals Co.'s copper refinery at Perth Amboy, to take charge of its experimental work in the field. C. R. Van Arsdale, who has been in charge of the testing plant at Douglas, is now in charge of this work at the New York office. A great deal of careful investigation is being done for the Calumet & Arizona company, but results are not ready for publication. The directors of the Tamarack have voted to expend \$250,000 in the construction of a regrinding and leaching plant to handle the tailing which has accumulated in Torch lake. The attention of everybody has turned strongly toward hydrometallurgical processes in order to recover the large amounts of copper which are now being lost in the tailing or remain unutilized in low-grade oxidized ores that are rebellious to present methods of treatment.

At the annual meeting of the Utah Copper Co., William Loeb, Jr., and W. Hinckle Smith were elected directors to succeed T. W. Lamont and Daniel Guggenheim. The advent of Mr. Smith on the board of the Utah Copper is interesting as another example of the way in which the big copper companies are getting together by the aid of interlocking directors. The Consolidated Copper Mines is the best example of the gathering of all the principal copper operators on the board of one company. Mr. Smith has been on the board of the Nevada Consolidated for some time.

Action in regard to its dividend was postponed by the Greene Cananea board at its last meeting, the intention being to await the outcome of the Mexican troubles in order to learn whether operations are likely to be curtailed in the immediate future. The American staff of the mine and smelter went back on May 1, it being evident that there was no immediate danger of hostilities directed toward Americans. The American staff at Nacozari went back to work the day before. A good deal of discussion seems to have been started in regard to the concentrate from the Real del Monte plant of the United States Smelting, Refining & Mining Co. at Pachuca, arising out of the fact that a while ago, when the Aguascalientes plant of the A. S. & R. Co. was in difficulties, that Company notified the Real del Monte that it would have to send its concentrate either to Monterey or Perth Amboy for the time being. As the freight to these places is greater, the concentrate was stored, in the expectation that the Aguascalientes plant would soon be able to take it again. As this has not been the case, some shipments have recently been sent to Europe to see what rates and returns can there be obtained. The total value of the concentrate does not cut a very big figure in the gross earnings of the Company.

ST. LOUIS, MISSOURI

ST. JOSEPH LEAD CO. ANNUAL MEETING.—OPPOSITION TICKET.

Interest here in the annual meeting of the St. Joseph Lead Co., to be held May 13, is keen. Under the amended by-laws, thirteen directors annually are to be elected and this makes possible a clean sweep at any time. Robert Holmes continues in opposition and has circularized the stockholders against the management. At the last annual meeting 895,272 shares were voted. Of these, Mr. Holmes mustered 218,495, and 320,000 shares were held by the Jones-Camp interests. The Doe Run-St. Joe consolidation has been effected; about 95% of the Doe Run stock having been exchanged. Clinton H. Crane, who succeeded Dwight E. Jones as president on the death of the latter, has made many of the changes recommended by J. R. Finlay and Mr. Kendrick, the experts employed, by agreement, to examine the mines and railway, respectively, but not all of them. O. M. Bilharz is now in charge of all the mills and C. J. Adami of the mines. Their work is highly commended on all sides, and it is known that they are reducing the already low costs materially. Holmes and his friends object to the continuance of Roscoe Parsons as 'resident manager' and to other hold-over appointments. They protest that the recommendations of Mr. Finlay, who is no longer with the Company, have been disregarded in important particulars; and also that certain bankers have been favored by the methods of financing adopted, whereas the indebtedness should have been wiped out by appropriations from earnings. Holmes has proposed an independent ticket which includes, aside from representatives of the Jones, Camp, and Parsons families, such well known technical men as Arthur Thacher, O. M. Bilharz, Gus Setz, and others personally familiar with the property. The St. Joseph Lead Co. is a rich and powerful concern, and one in which St. Louis people are heavy owners. It is hoped that a satisfactory solution of the Company's troubles will soon be found.

BIRMINGHAM, ALABAMA

CONDITIONS IN THE SOUTHERN STATES.—CHEAP MINING.—BIRMINGHAM'S GROWTH.—MINING IRON ORE.—GOLD MINING.—NEGRO LABOR ABOUT MINES.

A recent extensive trip to a number of mining districts in the southern states may be summarized as follows: In contrast to general conditions in some other parts of the country, business seemed to be on the increase, in spite of the supposed dull condition of 'things southern.' Activity in mining is due partly to a better appreciation of the natural resources in that part. Several factors contribute to the economical working of the ore deposits. Prominent among these is the presence of important coalfields in Alabama and West Virginia, and this is a particularly favorable factor for the extensive but low-grade iron ore beds of the South. The ore is mined cheaply, mostly by negro labor, and in the Birmingham district is turned into pig iron and steel within a short walk of the mines. Furthermore, it is not generally appreciated that Birmingham, the distributing point, is practically as far west as Chicago, and can compete with advantage in the southwestern trade as well as enjoy a monopoly in the southeastern states.

Birmingham is rivaling some of the Pacific Coast cities in rapidity of growth, having increased from 38,000 in 1900, to 180,000 today, and is styled by its boosters as 'the city with a payroll of a million a week.'

Another factor making for economical production is cheap negro labor. Undesirable as the negro is as a neighbor, and

ONE OF THE 'RED ORE' MINES OF THE TENNESSEE COAL, IRON & RAILWAY CO., ON RED MOUNTAIN, NEAR BIRMINGHAM.

in some states he outnumbers the white man, still, since he is there, he makes a better workman than is commonly supposed, especially on work at which a white man would get impatient. In some districts the negro miners are paid \$1.25 per day. It was 75c. per day a few years ago. In other places he receives more, especially where the mining is on contract at, say, 30 to 50c. per ton on the train cars. For a long time the prevalence of this cheap labor kept modern mining machinery out of the mining districts; but now a number of steam-shovels, locomotives, tramways, belt-conveyors, etc., are replacing the colored man and his mule. Incidentally, the mule is still an important asset in the smaller mines and pits, and in outlying districts.

It happens that the comparatively recent character of many of the geological formations tends toward flat-lying strata, and ore deposits close to the surface, or dipping at low angles. Thus, open-cut mines and pits are common. This applies to the brown iron ore deposits which are mined by steam-shovels, similar to the Mesabi range in Minnesota, and to the bauxite, phosphate, kaolin, and other deposits. The red iron ore, and coal, are mostly mined underground, through a slope, in place of a shaft with tripes taking the place of head-frames.

Gold mining is receiving quite an impetus by the success of one or two of the old mines of North Carolina, now worked on modern methods. One mine and mill there is making good profits from a 2 ft. vein yielding between \$10 and \$15

per ton. The vein is quartz, with slate walls. Heavy stamps, 1750 lb. each, dropping 105 to 110 times per minute, are used. Other plants consist of Parral tanks, filter-presses, and general all-sliding equipment. A controversy recently arose over one mine taking ore from across the boundary line of its neighbor, and as there was no state law against this, the manager of the offended company had a law passed in the legislature providing appropriate fines. Negro labor does not seem to be so well liked in the gold district as in some other parts of the country. To a manager or foreman used to capable white miners and skilled millmen, they are provoking, to say the least. They require a boss who understands their qualifications and failings. There has been more or less 'tinkering' with gold prospects in Georgia, and some talk of looking into the old mines in Virginia and Maryland. Gold in the Appalachians was quite important at one time.

BOSTON

BOSTON & MONTANA DEVELOPMENT Co.'s PROPERTIES.—EXCELSIOR CONSOLIDATED GOLD MINES.—STOCK EXCHANGE FAILURE.—BOSTON'S VIEWS ON MEXICO.—HALL LITIGATION.

Freeman I. Davison left Boston for London on May 4, to join Sir Robert William Perks, of MacArthur Brothers & Perks, Ltd., which interests have assumed the financing and construction of the Southern Montana railway south of Butte. This starts at Silverbow station on the Butte, Anaconda & Pacific line, and runs south through Deer Lodge and Beaverhead counties, branching off at Dewey's, up the Wise river, to Elkhorn and at Ralston, up the valley to French Gulch. At these two points the Boston & Montana Development Co. has mining properties. It is estimated that at least \$2,500,000 will be expended, beginning about July 1, building this road, which will be about 110 miles long. When the road is extended to Butte it will have a length of about 130 miles. The MacArthur-Perks interests sent their engineer to inspect the ground and check up conditions, and he has reported the situation much better than it had been represented to him. The Elkhorn mining property has large ore deposits. Governor Allen, president of the Company, estimates that there is 72,000,000 tons of commercial ore down to a depth of 1200 ft. The stock of the Company has been quite active on the New York Curb, being listed last December, selling at \$5 and since moving up to \$9 per share. It is expected that English investment interests in the Company, which owns the railroad to be built, will eventually become considerable.

A number of Worcester capitalists have subscribed the necessary money for settling the lawsuit of the Excelsior Consolidated Gold Mines, of the Meadow Lake district, Nevada county, California, and a corporation has been formed under Arizona laws, with 3,000,000 shares, \$1 par value. It is expected that the mines will be reopened about June 1. The Pacific Gas & Electric interests have built a good road from Cisco, 7 miles, to the mine. The plans of the new management are ambitious, consisting of blocking out 200,000 tons of ore per year. The ore is said to average \$10 per ton. The Excelsior was discovered about 50 years ago and has been worked intermittently, a good deal of the time being in the courts. About 10 years ago there was continuous work going on there, and it is said that the ore left is of good value. The Company has a small stamp-mill roasting plant, bunkhouse for 50 people, and excellent water-power and timber. A shaft is down 135 ft. on Excelsior vein No. 1. It is said that there is about \$35,000 in concentrate left in the bins. The management expects eventually to develop a capacity of 500 tons per day, treating ores by amalgamating and cyaniding.

The Gay & Sturgis Stock Exchange failure here is expected to show liabilities in excess of assets of about \$1,000,000. The

Company specialized on Lake issues and was largely interested in the Smokey Development Co. of Ely, Nevada, and the Terrible Dunderburg mines of Colorado, which issue the house had been planning to list on the Stock Exchange. The head of the house, Mr. Gay, is an invalid. The failure was another hard hit at the Lake stocks, which have had more than their share of trouble. Ahmeek, one of Mr. Sturgis' favorites, dropped 45 points on the sale of only 173 shares. Other stocks to suffer from being thrown on the market were Osceola, Wolverine, and Quincy. The Company owned also 3500 shares of Houghton Copper, 12,000 shares of Chief Consolidated, 3000 shares of Superior & Boston, and blocks of North Butte, Calumet & Arizona, Shattuck-Arizona, and Mohawk, besides local mill shares and bonds.

Boston copper traders generally would be glad to see a good war with Mexico in order to clean-up the situation there, believing that it would result in a big mining and copper boom. The shutting down of Greene Cananea, Mocetzuma, and the Guggenheim and United States Smelting properties, followed by sharp declines in these stocks, is not relished by Boston.

The suit of J. M. Hall, a Boston lawyer, against the Stock Exchange house of Paine, Webber & Co., alleging 'bucketing' of orders, drags along and draws into it many elements of past market feuds. A willing witness in behalf of the plaintiff has been Thomas W. Lawson, whose feeling against William A. Paine goes back for nearly ten years, to the time of the 'Copper Range war.' Another witness in the case is George E. Learnard, formerly a member of the Paine-Webber house, and afterward a member of Hooley, Learnard & Co., who is suing Lawson for certain amounts alleged to be due him in the Nevada-Utah 'clean-up' made by Lawson in the market here in the early part of 1907. The testimony of Lawson and Learnard has sharply crossed at several points.

The annual reports of Alaska Gold and the porphyry copper groups this year are said to be the most comprehensive and graphic ever put forth in mining literature. These interests go in strong for publicity.

TORONTO, ONTARIO

DIAMONDS IN ONTARIO.—THE MINING CORPORATION OF CANADA, LTD.—DOME REPORT.

The Ontario Bureau of Mines has issued a report announcing that the occurrence of diamonds in the province has been established. A sample of chrome iron ore, from Reaume township, about 20 miles north of Porcupine, was sent for examination to R. A. Johnston, of the Canadian Geological Survey, who a few years ago found small diamonds in British Columbia ore. Mr. Johnston reported that numerous microscopic diamonds occur in the ore. The discovery is one of scientific rather than economic interest, as the diamonds are too minute to have any commercial value. The rock in which the ore occurs is peridotite, a basic formation which weakens rapidly to serpentine. It is found extensively in the Porcupine area, and one analysis shows platinum to the value of \$1.50 per ton, which might be available as a by-product.

Special meetings of the shareholders of the Cobalt Township, Cobalt Lake, and City of Cobalt companies, held in Toronto, have ratified the merger of these Companies, arranged in England and approved by the English holding companies. The properties represented will be transferred to the new operating company incorporated under the name of The Mining Corporation of Canada, Ltd.

The Dome during the fiscal year ending March 31, 1914, crushed 101,812 tons of ore, yielding gold worth \$1,043,995, the average per ton being \$10.25. Compared with 1912 the tonnage milled showed an increase of 44%, and the output an increase of 13%, while the average value per ton was \$1.96 less.

General Mining News

ALASKA

The U. S. Geological Survey has just completed its preparations for the annual campaign of investigating the mineral resources of Alaska, the field plans for the year having been approved by the Secretary of the Interior, Franklin K. Lane. The parties have been made up, and some of the horses and other equipment purchased. Making surveys in the isolated parts of the territory requires preparation long in advance, and part of the supplies are shipped in over the winter trails on account of the difficulties of summer transportation. For this season's work supplies were started inland from the coast early last January and are now cached at convenient points situated 200 to 300 miles inland for use of the parties during the working season, which lasts from June through September. Eleven parties will be put in the field this year, and as in the past special heed will be given to the investigation of the resources of those districts which are tributary to the several routes that have been advocated for the proposed government railways.

A party under the leadership of J. W. Bagley and Theodore Chapin will undertake the exploration of the region tributary to Talkeetna river and will connect with the surveys of the Broad Pass region made last year. This party, consisting of seven men with fifteen horses, will go up Matanuska river early in June, and start work near the scene of the new gold discovery on Albert creek. It will penetrate a region now but little known, lying in the headwater country of Talkeetna river. On returning, the party will sur-

MAP OF ALASKA.

vey the region between the headwaters of Matanuska and Copper river, that has been advocated as a railway route.

An exploration of the region lying between Lake Clark on the east and the Iditarod district on the west will be undertaken by R. H. Sargent and Philip S. Smith. Here there is a belt of country, over 100 miles wide, which is almost an entire blank on the map. The party, made up of seven men, with twenty horses, will follow a route that has been suggested for a railway into the great Kuskokwim basin.

A. G. Maddren will investigate the gold-placer districts tributary to the lower Kuskokwim. He will ascend Iditarod river, by canoe, portage across the divide to reach the Kuskokwim, and visit the Aniak, Tuluksak, and Goodnews Bay placer districts.

Stephen R. Capps and C. E. Giffin will carry geologic and topographic surveys across Skolai pass into the White River basin and thence to the international boundary. This is

also a region where railway building has been considered. Mr. Capps will give special attention to the investigation of the newly discovered gold district in the Chisana basin. This work is an extension of previous reconnaissance surveys in this field.

A detailed base map will be made of part of the Juneau district, now the most important gold lode camp in Alaska, and promising to become one of the most important on the continent. The purpose of the base map is to make possible an exhaustive study of the occurrence of the gold ores. D. C. Witherspoon will undertake the making of the base map, which will be on a scale of three inches to the mile.

A detailed survey of the Kotsina copper-bearing area was undertaken in 1912, but unfortunately the delay in the appropriation during the last two years has prevented its completion. It is planned that F. H. Moffit and J. B. Mertie now complete this work. B. L. Johnson, with one assistant, will undertake the detailed geologic survey of the Port Valdez gold and copper district. The base map necessary for this work was completed in 1913.

To coördinate and correlate the various geologic surveys in Alaska, it is necessary to continue the studies of the general geology and mineral resources. Three geologists will be engaged in this work during 1914. George C. Martin, assisted by R. M. Overbeck, will continue his studies of the Mesozoic stratigraphy. He will visit important localities in southeastern Alaska in the Chitina valley, and along the Yukon.

H. M. Eakin will undertake supplementary investigations of the tin deposits of Alaska. He will examine some of the occurrences of tin in the York region of Seward peninsula and in the Hot Springs district of the Tanana valley. Mr. Eakin will also undertake some general studies of the occurrence of mineral deposits and mining development in the Nome, Fairbanks, and Juneau districts.

Alfred H. Brooks, the geologist in charge of the Alaska surveys and investigations, expects to leave for Alaska as soon as office work permits, probably about the middle of June. He will devote special attention to the problems of Quaternary geology, including the genesis and occurrence of placer deposits. He will visit the Iditarod and Fairbanks districts and, time permitting, the Nome district. Mr. Brooks will also join the Moffit party in the Kotsina district and the Johnson party in the Valdez district for brief periods of time.

KETCHIKAN

(Special Correspondence.)—The property of the Alaska Venture Syndicate, 20 miles from this place, and controlled by the Great Boulder Proprietary of Western Australia, is developing fairly well. The natural facilities for economical mining and milling are so good that \$3 ore can be handled at a profit, on a tonnage of say 250 per day. This district has possibilities, but 'wild-cat' schemes several years ago greatly retarded interest and development.

Ketchikan, March 11.

NOME

The Noatak-Kobuk region is the subject of *Bulletin* 536 by Philip S. Smith of the U. S. Geological Survey. In the preface, Alfred H. Brooks describes what is known as an area of 150,000 square miles of the territory above the Arctic Circle. The Noatak river region is around 68° latitude north. The mean annual temperature is about 16.5°, ranging from -31.3 to 60.8 F°. Game and fish are fairly plentiful. Quartz veins are numerous, the older being in schists and limestones. About \$100,000 has been recovered from gravel in the Shungnak region. The other river deposits are described. Copper ores are also found. The cost of supplies and operations will not decrease much in the future, but assiduous prospectors, properly equipped, may find the country worth investigation.

ARIZONA

The Arizona State Tax Association has assessed the mining properties in the state at \$111,453,208, of which Cochise county contributes \$50,077,213.

COCHISE COUNTY

A modern dispensary, constructed of brick and to cost \$35,000, is being erected by the Copper Queen Consolidated company at Bisbee. Practically all the officials of the Mochizuma Copper Co., of Sonora, Mexico, have returned to Mexico. The general manager, C. I. Schuster, reports that production went on without interruption during his absence, capable Mexicans having been left in charge.

GILA COUNTY

During the quarter ended with March, the Iron Cap mine, at Globe, produced 343,141 lb. of copper and 19,663 oz. silver, returning \$37,689. The mine expense was \$21,620. Development at No. 8 level is opening good ore. Additional claims will probably be bought.

(Special Correspondence.)—Lessees at the Gibson mine are mining about 300 tons of high-grade ore per month, but the expiration of the present lease will end high-grade operations. O. B. Kemp and associates, who control the property, state that a 100-ton per day flotation plant will be installed before the end of summer. Tests show a recovery of 85% of the copper by this process.

Ore shipments from the Iron Cap averaged a carload per day during the latter part of April. This from the 800-ft. level, where the average is 7% copper and some silver.

About 20 ft. of ore was cut on the 1300-ft. level of the Arizona Commercial. April production of the Superior & Boston was about 70 cars of ore, containing from 5 to 10% copper.

Globe, April 29.

(Special Correspondence.)—The swelling nature of the ground in which the main shafts of the Inspiration mine have been sunk has given trouble in obtaining a good footing in the upper portion. Concrete is dropped through a vertical 4-in. pipe from the surface, a fall of over 300 ft. resulting in good tamping. A 16-ft. section is poured per day of three shifts. It was found advisable to concrete around the timbers. Good progress is being made at the mill shops and smelter. Work at the Inspiration Extended is promising, and ore is expected at 400 feet.

Miami, April 29.

(Special Correspondence.)—Probably an 80-ton concentrating plant will be erected by P. F. Curney and J. R. Davis, the new owners of the Gibson mine, to treat the low-grade sulphide ore. The richer ore is sent to smelters.

Gila Bend, April 30.

CALIFORNIA

Following is a tabulation of minerals concerning which final returns for 1913 are available to date, according to the California State Mining Bureau:

| Mineral. | 1913. | | 1912. | |
|---------------------|-----------|-------------|-----------|-------------|
| | Amount. | Value. | Amount. | Value. |
| Cement, bbl. | 6,167,806 | \$7,743,024 | 6,198,634 | \$6,074,661 |
| Chromite, tons | 1,180 | 12,700 | 1,270 | 11,260 |
| Coal, tons | 25,198 | 85,809 | 14,848 | 39,092 |
| Graphite, lb. | 2,500 | 25 | | |
| Infusorial earth, | | | | |
| tons | 8,595 | 35,760 | 4,129 | 17,074 |
| Iron ore, tons..... | 2,343 | 4,485 | 2,508 | 2,508 |
| Marble, cu. ft..... | 41,654 | 113,282 | 27,820 | 74,120 |
| Pyrite, tons | 79,000 | 218,537 | 69,872 | 203,470 |
| Pumice, tons | 90 | 2,000 | 100 | 2,500 |
| Tungsten ore, tons. | 7,592 | 234,673 | 8,042 | 206,000 |
| Totals | | \$8,450,295 | | \$6,630,685 |

AMADOR COUNTY

It is said that B. Shuttleworth, recently arrived from Australia, has organized a company to erect cyanide plants at Defender and Drytown, to treat old tailing dumps there. A meeting of the Plymouth Consolidated company was held in London during April. On a tonnage of 8000 per month, the profits should be \$2.46 per ton, according to W. J. Loring.

BUTTE COUNTY

It is reported that H. Bartram has opened zinc ore on the Magalia ridge. A plant containing a roller mill with arrastra attachment will be started at the mine owned by H. Hamilton, D. E. Willis, and M. Stroehl at Inskip. During the week ended March 28, two dredges of the Oroville Dredging Co. recovered gold worth \$5625.

CALAVERAS COUNTY

Fire destroyed property valued at \$10,000 at Copperopolis on April 27. The houses were owned by the Calaveras Copper Co. and were insured.

ELDORADO COUNTY

There is more activity in the Empire district than for some time past, and several properties have changed hands.

NEVADA COUNTY

The trouble in Mexico, which resulted in the stoppage of traffic on the Tehauntepec railway, is likely to interfere with treatment at the Champion, North Star, Empire, and Pennsylvania mills at Grass Valley and Nevada City, as a shipment of cyanide has gone astray. The annual meeting of the Consolidated St. Gothard (Delhi) Gold Mining Co. was held at San Francisco on April 24. A long ditch and flume for water-supply has been constructed. The mine has been well developed, and the 20-stamp mill will soon be at work, again.

SAN BERNARDINO COUNTY

(Special Correspondence.)—A 100-ton cyanide plant has just been erected at the Waterman mine, at Barstow, by George B. Phillips. Results so far have been satisfactory.

Barstow, May 1.

SHASTA COUNTY

All hope of extinguishing the fire in the Midas gold mine has been abandoned. The manager, W. H. Roberts, has stated that it can only burn on the 1200 and 1300-ft. levels. In the meantime the mine is filling with water. This will take six weeks to reach the 1200-ft. station. The Mammoth Copper Co. is repairing and enlarging the bag-house at the smelter, the cost to be about \$75,000.

SIERRA COUNTY

Work has been suspended at the Alaska mine at Pike, and 50 miners are attacking a landslide which threatens to carry the 40-stamp mill into the cañon. A drift, to open gravel in the Mountain House drift mine, is in over 210 ft., and is nearing the channel. The new mill at the Mexican quartz mine is nearly ready for work.

SISKIYOU COUNTY

(Special Correspondence.)—Messner & Cory have finished a test run on 13 tons of ore from their mine in Cedar gulch, and are pleased with results. Developments on the vein disclose a shoot of good ore. They have leased the French John hydraulic mine and are working good gravel. A shoot of rich ore has been intersected in the Big Cliff, in the Salmon River district. Los Angeles people are developing the Hardscrabble mine on South Russian creek, and fair-grade ore has been opened. Work has been resumed at the Highland, under John Mattern. Operations have been resumed at the Homestake, Cub Bear, and several other quartz mines in this district. Conditions are favorable for a long season, as an abundance of water is indicated far into the fall months. The Akin Mining Co. of San Francisco, has started work

at its placer holdings near Oak Bar. Explorations are being conducted with a view to installing a dredge. A. L. Akin is manager. Good ore is being milled at the Gold Run mine, near Gilta. The property is opening in good shape, and additional mine equipment is contemplated. R. W. Bender is superintendent. Los Angeles people recently inspected the Commodore and other properties in the Oak Bar district, and are reported to be negotiating for a number of small quartz and placer mines.

Etna Mills, April 25.

TRINITY COUNTY

It is said that a syndicate has acquired options on about nine miles of dredging ground along the Trinity river, including that of the Alta Bert and other companies. A large number of holes have been drilled to prospect the gravel. John Hays Hammond is expected in the district at an early date.

TUOLUMNE COUNTY

Specimen ore has been opened at a depth of 125 ft. in the Carlin mine by the Jamestown Exploration Co. Four veins are said to junction at this point. The Rawhide mine has been purchased by Eastern people. It is reported that the Melones Mining Co. may install more stamps in its present extensive plant.

The suit of Thomas A. Fisher against all the owners of the Black Oak mine, which was tried at Sonora last fall before Judge Plummer and decided in favor of the plaintiff, was settled on April 29, he accepting the \$119,000 left on deposit in full payment for the balance of the money due on the mortgage indebtedness he held against the property.

COLORADO

EAGLE COUNTY

Reports have been made of the discovery of high-grade gold ore in the Fulford district. As soon as the snow has disappeared, active work will be started.

LAKE COUNTY

A local branch of the Colorado Metal Miners' Association has been formed at Leadville.

TELLER COUNTY (CRIPPLE CREEK)

A contract for the installation of equipment for extending the Roosevelt tunnel has been signed by Harry J. Gehm, general manager for the Colorado Trading & Transfer Co. Work is to be done through the El Paso shaft, from which all rock will be removed to the surface. High-graders are busy in the Mary McKinney mine, and a collision with the sheriff is expected.

The estimated output of the district in April was 85,552 tons having a gross value of \$1,214,921.

Dividends paid during the month totaled \$176,189, contributed by the following: Golden Cycle, \$45,000; Mary McKinney, \$26,189; Portland, \$60,000; and Vindicator, \$45,000.

IDAHO

SHEOSHONE COUNTY

The Bunker Hill & Sullivan company paid dividend No. 200, of \$81,750, on May 4. The total to date is \$15,138,000. The output in 1913 was 436,000 tons of ore worth \$3,889,758. The net profit was \$1,062,512. It was 15 years, on April 29, since the mill was dynamited. From 72,901 tons the Ontario Mines Co., in 1913, had a return of \$592,372, and profit of \$183,791. The Sierra Nevada mine produced 5031 tons of ore worth \$19,458, in 1913, but there was a loss of \$6047 on operations. The Stewart Mining Co. produced 174,126 tons of ore in 1913 worth \$1,629,474, at a cost of \$1,068,040, leaving a profit of \$561,434. The Gold Hunter Mining Co. mined 114,000 tons of ore, in 1913, worth \$489,148, resulting in a small loss on operations. The Snowstorm Mining Co. produced 105,674 tons, worth \$709,577, with a profit of \$137,455. The Hecla

Mining Co.'s yield in 1913 was 141,930 tons, valued at \$1,026,755, yielding a profit of \$292,696. The Alice Mining Co.'s return was 31,908 tons, worth \$14,912, and a loss of \$3674.

MICHIGAN

HOUGHTON COUNTY

Sand from the Redridge mill of the Copper Range Consolidated is being sent to the Company's Champion mine at Painesdale for filling old stopes. When the Baltic and Tri-mount mines are ready for sand, the Copper Range railroad will move 30 cars per day from the above mill, also the Freda and Beacon Hill. The Mineral Range Railroad is moving 'rock' from 10 mines regularly and two intermittently.

ONTONAGON COUNTY

On the White Pine property, owned by the Calumet & Hecla company, and on which a large sum of money has been spent, material for a stamp-mill is being sent to the mine, to be erected this summer. The claims are in an isolated spot. The vein is narrow and irregular, and copper occurs in sandstone, but the 'rock' is rich.

MONTANA

CASCADE COUNTY

On the west side of the Missouri river, near Great Falls, the Power City Oil & Natural Gas Co. has its first hole down over 200 feet.

MISSOULA COUNTY

In the Saltese district, the Monitor and adjoining properties are to be consolidated, and a long adit will be driven to prospect the claims from the St. Joe side of the range. This will give a depth of 1700 ft. to cut the copper-gold ores.

SILVERBOW COUNTY

A report for the first quarter of 1914 has been published by the North Butte company, and shows that 4531 ft. of development was done, the Granite Mountain shaft being sunk 225 ft. to 10 ft. below the 3000-ft. station. Ore production was 118,187 dry tons, yielding 6,172,158 lb. copper, 365 oz. gold, and 374,833 oz. silver.

A contract has been let for an addition to the Butte-Duluth leaching plant costing \$100,000. This will be a 100-cell electrolytic plant, the present one having 47 cells, capable of treating the solutions of 300 tons of ore. The complete plant will have a daily capacity of 1000 tons. Estimates of ore available by open-cut mining are 15,000,000 tons.

On the 1400-ft. level of the Butte & Superior's Black Rock claim, the orebody is 1500 ft. long. In places it is 100 ft. wide. Reserves ready for stoping in the mine, above 1400 ft., are estimated at 1,125,000 tons.

During the eight months ended March 1, 1914, the Davis-Daly Copper Co. has produced 49,095 tons of ore averaging 3.08% copper and 6.2 oz. silver per ton. Mining cost \$5.66 per ton. Development during the past year totaled 8247 ft. It has been decided to sink the Colorado shaft from 2000 to 2600 ft. An assessment of 50c. each has been made on the stock.

NEVADA

ESMERALDA COUNTY

The estimated production of the Goldfield Consolidated company in April is as follows: ore treated, 28,215 tons; gold recovered, \$324,000; operating expenses, \$171,000; and net production, \$153,000. The Jumbo Extension company has paid the second installment of the option on the Velvet claim from the Goldfield Merger company. Encouraging development is being obtained from the Atlanta mine. The sum of \$50,000 has been raised by James Golden for a mill in the Klondike district.

NYE COUNTY

Work has been resumed by the Railroad Valley Co. in its

prospecting for potash deposits. The geologist, E. E. Free; superintendent, D. H. Walker; and driller, Mr. Weaver, recently left Tonopah for the property. The MacNamara Mining Co. is to be reorganized.

UTAH

JUAB COUNTY

Part of the new Knight-Christensen mill is in operation. The face of the adit driven 1900 ft. into the Dragon Consolidated shows gold-silver ore averaging \$40 per ton. During April the Eagle & Blue Bell mine produced 2544 tons of ore worth about \$50,000.

SALT LAKE COUNTY

It is reported from Boston that the Utah Copper Co. will construct an immense leaching plant to treat the carbonate ore capping on the orebodies. The first unit will be of 2000-ton daily capacity, and the ultimate cost of the 10,000-ton plant about \$2,000,000.

SUMMIT COUNTY

Ore worth \$54,800 has been extracted from the Easter vein, in the American Flag mine, since it was discovered a year ago. Also 12,000 tons of \$15 ore has been blocked out for the mill. Shipments from the district in April amounted to 5289 tons, of which the Daly-Judge and Silver King Coalition contributed 2764 and 2157 tons respectively.

MEXICO

The Mines Company of America operates the Dolores and El Rayo mines in Chihuahua, and the Creston-Colorada and La Dura in Sonora. The report for 1913 contains the following information: Development in the Dolores showed good results, and reserves at the end of the year were 100,932 tons, assaying \$14.18 per ton. Costs were reduced by \$2 per ton treated. Owing to bandits, the mill was stopped on September 1, and the mine three weeks later. El Rayo was forced to suspend work on July 10, but will resume this month. Mining proved the extension of the known orebodies. Reserves are 54,800 tons of \$14.60 ore. The Creston-Colorada and Grand Central produced 130,664 tons of ore worth \$810,514. At the beginning of 1914, ore reserves were estimated as 306,300 tons averaging \$5.33 per ton. The Grand Central promises to be a profitable investment. Both mines and plants operated continuously during 1913. It is proposed to increase the monthly output from 10,000 to 18,000 tons of ore. From the Gloria and Prieta mines at La Dura, there were produced 4869 tons. The stoping operations carried on in these properties have proved the persistence of the veins. The Gloria vein, below the 900-ft. level, is showing strong and producing a good grade of ore, while on the 1040-ft. level of the Prieta mine, stoping shows a good tonnage of high-grade ore. Ore reserves are 23,229 tons, assaying \$44.24 per ton. Partly on account of the interruption to railway shipping facilities and partly on account of President Wilson's proclamation urging Americans to leave all isolated camps in Mexico, operations were suspended in September. The property is in charge of the *presidente* of the town, and has not been molested in any way. It is intended to resume operations upon the reestablishment of railway communication.

Ore reserves in all the mines are estimated to be 485,261 tons assaying \$4,888,605, compared with 334,876 tons assaying \$3,612,010 at the close of the preceding year.

The production of the Company's mines was 207,085 tons worth \$2,017,057. Revenue was \$1,734,626; operating profit, \$495,987; and net profit, \$467,232. The consolidated balance sheet of the Company shows current assets of \$1,539,378, accounts and drafts payable and suspense account \$392,065.

CHIHUAHUA

The Buena Tierra Mining Co., Ltd., which operates a lead-silver property in the Santa Eulalia district, 15 miles south-east of the town of Chihuahua, has just issued its report for 1913. Owing to the revolution, it was not possible to work continuously and the smelter at the centre was shut down on November 1, 1913. The ore mined was 25,972 tons, averaging 14.01% lead and 8.22 oz. silver. Net returns from the smelter were \$6.99 per ton, or \$181,689. Working costs were \$3.47 per ton, or \$89,512. The year's profit was \$77,000, after adding sundry receipts. The amount carried forward was \$97,000. Ore reserves are estimated at 300,000 tons. Generally, the year's results were satisfactory.

MEXICO

The Mexican Mines of El Oro produced bullion worth \$140,-

MAP SHOWING PROPERTIES OF MINES COMPANY OF AMERICA.

580, from 10,750 tons of ore, in March. The profit was \$94,070.

SONORA

On May 1, a special train containing 125 American men, including J. S. Williams, Jr., of the Moctezuma Copper Co. of Nacozari, and L. R. Budrow, of the Tigre Mining Co. of El Tigre, left Douglas, Arizona, for these places. Officers of the Cananea Consolidated Co. returned on May 7 to resume operations. Guns and ammunition taken from the Americans when they left are to be returned. Three things were responsible for the decision to return to Nacozari and El Tigre and resume operations. They were: a cordial invitation from the Mexican officials, telegraphic advices from Washington, and the raising of the embargo on the exportation of all products into Sonora except food. This assures the mining companies of fuel for operating purposes.

Personal

A. M. POXTIE has gone to Brazil.
A. E. THOMAS has gone to Portugal.
THOMAS A. VARDEN is in New York.
SYDNEY H. BAIL has gone to Europe.
R. A. ARCHBOLD has returned from Nigeria.
JAMES B. RISQUE was in New York last week.
ERNEST WILLIAMS has gone to Dutch Guiana.
NELSON DICKERMAN, of Pato, Colombia, is in London.
P. N. NISSEN was in New York last week and has gone to Chicago.

FREDERIC E. CAULKINS is in Graham county, Arizona, inspecting mining property.

H. P. DAVIES has left Barranquilla, Colombia, and has made his home in London.

WILLIAM J. ELMENDORF, formerly of Victoria, is now at Stewart, British Columbia.

H. D. GRIFFITHS has gone to India, but expects to return to England at the end of June.

JOHN T. RED has recently been in the Jarbidge district, Nevada, making extensive mine examinations.

H. A. BEUFILER is in St. Lukes hospital at St. Louis on account of infection following tonsillitis. He is recovering slowly.

F. L. G. KNOX has resigned as manager for the Natomas Consolidated and has been succeeded by Emory Oliver, formerly chief engineer.

R. H. FERNALD has been appointed a consulting engineer of the Bureau of Mines. He will go to Europe to make departmental investigations.

MARK R. LAMB is expected in San Francisco soon. During his absence from Chile, F. KARL LAMB will look after the Allis-Chalmers interests.

CARLTON R. ROSE has resigned as superintendent for the United States Zinc Co. to join the San Francisco staff of Smith, Emery & Company.

T. A. RICKARD is expected to arrive in New York on May 27, to attend the celebration of the fiftieth anniversary of the Columbia School of Mines.

WILLIAM C. EDLES of San Francisco, and Lieutenant FREDERICK MEARS have been appointed members of the Alaskan Railroad Commission by the President.

LAWRENCE ADDICKS has been engaged by Phelps, Dodge & Co. to take charge, in the field, of the hydrometallurgical research which that Company has under way.

ROY WETHERED, formerly with the Consolidated Mining & Smelting Co., of Canada, has opened an office as mining engineer in the Paulsen building, Spokane, Washington.

The following mine safety field meetings, at which the U. S. Bureau of Mines will cooperate, are to be held in May: 2nd, Saline County Mine Safety Association, Harrisburg, Illinois; 9th, Kentucky Mining Institute, and Kentucky Mine Operators' Association, Lexington, Kentucky; 13th to 15th, West Virginia Medical Association and Pocahontas Coal Operators' Association, Bluefield, West Virginia; 18th, Fort Smith, Arkansas; 21st, McAlester, Oklahoma; 25th, Pittsburg, Kansas; 28th, Moberly, Missouri; and at Des Moines, Iowa, on June 1.

The Rocky Mountain branch of the Canadian Mining Institute held a meeting at Fernie, British Columbia, on April 27. Papers were read on mine-rescue work by Charles Graham and Francis A. Hall, and discussed by the members during the day, and in the evening W. R. Wilson entertained the visitors and others at a theatre party. The program included a tour of inspection of the Coal Creek, Michel, and Hosmer mines.

The UNIVERSITY OF CALIFORNIA will hold its fifty-first Commencement at the Greek Theatre, Berkeley, on May 13. The graduating class will consist of over 600, while there will be 300 recipients of higher and professional degrees.

AN effort is being made to have a large attendance of the Montana Section at the A. I. M. E. meeting at Salt Lake City, August 10 to 14.

A local charter has been granted to the Utah branch of the AMERICAN INSTITUTE OF MINING ENGINEERS.

The Metal Markets

LOCAL METAL PRICES

San Francisco, May 7.

| | |
|---|--------------|
| Antimony | 9 — 9¾ c |
| Electrolytic copper | 15 ½ — 15¾ c |
| Pig lead | 4.15 — 5.10 |
| Quicksilver (flask) | \$39.00 |
| Tin | 40 ½ — 42 c |
| Spelter | 6 ½ — 6¾ c |
| Zinc dust, 100 kg. zinc-lined cases, 7½ to 8c. per pound. | |

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, May 7.—The market may be summed up as follows: copper is very dull with no new features; lead is quiet but firm; and spelter is firmer, although it has dropped slightly. Exports of copper in April were 34,787 tons, against 45,973 tons in March. Outputs in April were: Braden, 2,720,000 lb. (a record); and Miami, 3,227,600 lb. Nevada Consolidated's first quarter yielded 15,597,595 lb., compared with 14,523,365 lb. in 1913. Greene Cananea mines and smelters are to resume work at once. The dispute between the Butte & Superior and Clark interests may be settled early. Business is dull on 'Change.' St. Louis prices for lead and spelter are 3.85 and 5c. per pound. Bar silver in London is 27½d. per ounce. The Stock Exchange there, and the Paris Bourse are dull.

SILVER

Below are given the average New York quotations in cents per ounce, of fine silver.

| Date. | Average week ending |
|-------------------|---------------------|
| Apr. 30..... | 59.25 |
| May 1..... | 59.12 |

| Aug. .. | 1914. 4.60 |
| Sept. .. | 1913. 4.70 |
| Oct. | 1914. 4.37 |
| Nov. | 1913. 4.16 |
| Dec. | 1914. 4.02 |

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can

usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

| Week ending | Apr. 23..... | 1913. 38.50 |
|-------------------|--------------|-------------|
| Apr. 9..... | 39.00 | 39.00 |
| " 16..... | 39.00 | 39.00 |

| May | 1913. 5.52 |
| June | 1914. 5.23 |
| July | 1913. 5.11 |
| Aug. | 1914. 5.51 |
| Sept. | 1913. 5.55 |
| Oct. | 1914. 5.22 |
| Nov. | 1913. 5.09 |
| Dec. | 1914. 5.07 |

London price of spelter in pounds (£) per ton, if divided by 4, gives the New York equivalent in cents per pound, including the duty payable. This does not include any allowance for freight. Shillings and pence should, of course, be reckoned as decimals of a pound.

At the beginning of April, spelter was quoted at around 5.27½c., New York, and 5.12½c. St. Louis; by the 15th, 2½ points had been lost, and immediately thereafter came one decline after another, until by April 24 the New York quotation was about 5.10c. and that at St. Louis about 4.95c. The declines followed smaller demand and pressure on the part of sellers to induce consumers to take metal. Producers and sellers were feeling in turn the falling off in business in galvanized sheets which was sufficient to not only curtail buying of spelter, but to cause reductions in the prices of sheets.

TIN.

New York prices control in the American market for tin, since the metal is almost entirely imported. San Francisco quotations average about 5c. per lb. higher. Below are given average monthly New York quotations, in cents per pound:

| Monthly averages. | 1913. | 1914. |
|-------------------|-------|-------|
| Jan. | 50.45 | 37.85 |
| Feb. | 49.07 | 39.76 |
| Mch. | 46.95 | 38.10 |
| Apr. | 49.00 | 36.10 |
| May | 49.10 | |
| June | 45.10 | |
| July | 40.70 | |
| Aug. | 41.75 | |
| Sept. | 42.45 | |
| Oct. | 40.61 | |
| Nov. | 39.77 | |
| Dec. | 37.57 | |

The Vulcan Detinning Co., which has plants at Sewaren, New Jersey, and at Streator, Illinois, reports as follows for the quarter ended March 31, 1914: Sales, etc., \$225,375; operating and office expenses, \$202,212; balance, with other income, \$23,502; previous surplus, \$414,881; and total surplus, \$438,383. The business generally is favorable, but the Company hopes for better prices in the steel and tin industries, by which its products largely are consumed.

ALUMINUM.

Quotations changed but little in April, and the market presented no features of especial interest. Quotations on April 23 were 18 to 18.25c. for prompt, 98 to 99% pure, and 17 87 to 18.12½c. for futures.

During 1913 the Aluminum Industry Co., of Neuhausen, Germany, made a net profit of \$1,288,000, compared with \$883,000 in 1912. A dividend equal to 20% on the capital of \$5,000,000 was paid. In view of the uncertain trade outlook it is said consumers of aluminum have been very cautious for some time in placing contracts, and the stocks in their hands have fallen to a low level, with the result that quick delivery is required for the contracts now being placed. It is announced that the International Aluminum Syndicate has still several years to run.

ANTIMONY.

This market was without features of interest in April except that dealers complained of low prices, some of them declaring that sales of Hallett's at below 7c. per pound were made at a loss. Prices changed but little in a dull market. For Hallett's, 6.75 to 6.95c. was asked; for Cookson's, 7.15 to 7.25c.; and other brands at 5.75 to 6.25 cents.

Mineral Production of Queensland in 1913

The output of various metals and ores last year was as follows, according to the annual report of the Under Secretary for Mines, A. R. Macdonald, published in the government *Mining Journal*:

| Mineral. | 1913. Tons. | 1912. Tons. |
|--------------------------|----------------|----------------|
| Bismuth..... | 1.60 | 5.95 |
| Bismuth and wolfram..... | 181.75 | 191.50 |
| Coal..... | 1,937,944 | 902,166 |
| Copper..... | 23,655 | 23,120 |
| Fireclay..... | 8,388 | 6,336 |
| Gems (value)..... | £43,292 | £40,016 |
| Gold ounces..... | 265,735 | 347,946 |
| Ironstone (flux)..... | 40,838 | 15,526 |
| Lead..... | 3,603 | 3,108 |
| Limestone (flux)..... | 161,165 | 97,175 |

| Wolfram..... | 358.75 | 626.5 |
| Total value..... | £3,857,881 | £4,175,355 |
| Dividends..... | 469,619 | 522,920 |

Fuel Briquetting in 1913

Briquetted fuel made in the United States is essentially for domestic use, for which there was a slackened demand last year, according to Edward W. Parker of the U. S. Geological Survey. In the eastern, central and Pacific coast states there was a total of 17 plants producing 181,859 short tons of briquettes, eggettes, coalettes, boulettes, etc., worth \$1,007,327.

OPERATING OFFICIALS of the Utah Copper Co., in Utah, in 1913, were as follows, according to the annual report: general manager, Robert C. Gemmell; assistant secretary and cashier, John M. Hayes; assistant purchasing agent, C. F. Jennings; chief engineer of mines, H. C. Goodrich; superintendent of mines, J. D. Shilling; consulting mechanical engineer, George O. Bradley; manager of mills, F. G. Janney; superintendent of Magna mill, H. C. Smith; and superintendent of Arthur mill, F. G. Janney, Jr.

OPERATING OFFICIALS of the Ray Consolidated Copper Co., Arizona, in 1913, were as follows, according to the annual report: manager, L. S. Cates; superintendent of mines, W. S. Boyd; consulting engineer of mines, R. C. Gemmell; consulting mechanical engineer, George O. Bradley; superintendent of mills, D. D. Moffat; consulting engineer of mills, F. G. Janney; and cashier, A. J. MacLean.

Bullion received at the San Francisco Mint during April was as follows: gold, 179,491 fine oz., worth \$3,710,403; and silver, 125,591 fine oz., worth \$73,014. The coinage executed was worth \$4,117,000—in double eagles, \$4,000,000; dimes, \$100,000; and nickels, \$17,000. Coin, bullion, etc., on hand on April 30 amounted to \$241,128,196.78.

Company Reports

NEVADA CONSOLIDATED COPPER COMPANY

The report of this Company for 1913 is of great interest, and contains plans of the mines, and fine large colored half-tones showing the geology of the porphyry copper deposits. C. B. Lakenan is general manager; E. E. Vanderhoef, mine superintendent; R. E. H. Pomeroy, acting superintendent of the Steptoe smelter; and Pope Yeatman, consulting engineer. The combined reports contain the following data: Ore reserves are estimated at 39,108,590 tons, averaging 1.65% copper, about 250,000 tons more than the previous figure. Drilling in the Josie-Montana ground has added to the reserves. The ore lies at the contact of limestone and porphyry, and is partly in both formations. Hope for proving more ore lies in sinking deeper holes in known orebodies, and this is to be done after moving the capping. Prospect holes drilled in the Copper Flat, Liberty, Eureka, and Veteran workings numbered 27, aggregating 9175 ft. The total to date is 307, with 93,377 feet.

Mining was done by underground caving at the Veteran, and steam-shovels at the Eureka, Hecla, and Liberty pits. These pits are in the one orebody, and produced 3,148,285 tons of 1.597% copper ore in 1913. Stripping amounted to 3,100,661 cubic yards.

Transport of ore to the Steptoe Valley plant cost 26.72c. per ton. This plant treated 3,139,137 tons of ore averaging 1.599% copper, producing 452,233 tons of concentrate assaying 7.61% copper. The recovery was 68.52%. There was also treated 280,041 tons of ore for the Giroux Consolidated Mines Co. A number of improvements were made to the concentrating, roasting, and smelting plants. The 18 roasting furnaces, in January 1914, treated 404,266 tons of concentrate. The reverberatories smelted 593,484 tons of produce. The converters produced 64,972,829 lb. of copper.

The gross revenue was \$10,225,493; net profit, \$3,483,886, including \$1,470,443 from dividends, interest, etc.; total profit, \$6,656,064, including balance from 1912; dividends paid in 1913, \$2,999,185; and balance at December 31, 1913, \$3,069,643.

MIAMI COPPER COMPANY

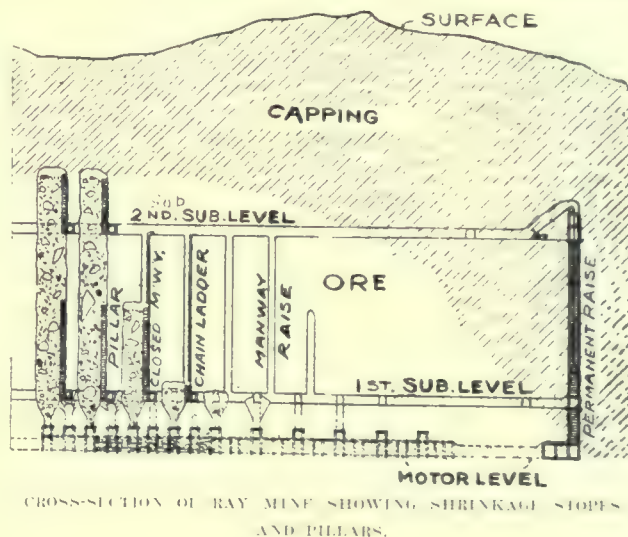

The general manager, B. Britton Gottsberger, reports as follows concerning the work done in 1913. The development totaled 37,697 ft., in drifts, raises, and shafts, at a cost of 31c. per ton. The ore extracted by stoping during the year is about equally divided between the shrinkage stopes in the Northwest orebody, and the square-set and slicing work in the eastern part of the mine. The ore in the East orebody has now been mined down to the 370-ft. level, with the exception of the shaft pillar. A new slice has been started below the 370-ft. level, and slicing of the shaft pillar is in progress. The shrinkage stopes in the southwest and northwest parts of the orebody have been completely broken, and blasting of the pillars between the rooms has progressed to the point where drawing of the broken ore in these areas can soon be started. Development work on the 420-ft. level, and above, was completed during the year in the older portion of the mine. The development of the Captain orebody, started in the previous year, is now well under way, and actual mining operations in this mine will begin during the current year. The sinking of the No. 1 or Captain shaft to the 420-ft. level was completed, thus furnishing an outlet from the mine to take the place of No. 2 shaft, which has been lost as the result of mining operations. Development work on the 570-ft. level was discontinued in the latter part of the year, as the outline of the orebody on that level has now been well defined, and actual mining need not begin for some time to come. The cave-in

last April interfered with mining for a time, and increased costs. Ore reserves are estimated at 20,300,000 tons, averaging 2.45% copper. This does not include 6,000,000 tons of 2% mixed oxide and sulphide ore, proved by drilling and underground work. Some leaching process may make this ore profitable. Churn-drilling has also developed 17,200,000 tons of 1.21% ore. Drilling amounted to 8774 ft. during 1913. The ore handled was as follows: stockpile, 101,888; development, 124,784; square-sets and slicing, 418,722; and shrinkage stopes, 409,890; a total of 1,055,284 tons. Stockpile costs were 35.6c., and mining, \$1.156 per ton.

The mill treated 1,058,784 tons of 2.3% ore, producing 45,410 tons of 38.09% concentrate, yielding 32,867,666 lb. of refined copper. The mill recovery was 71.06%, at a cost of 57.225c. per ton. The cost per pound of copper was 7.9c. Several efficient alterations were made and are being made to the mill. Sales of metal amounted to 33,134,334 lb., yielding a revenue of \$5,049,807. All operations cost \$2,515,122, leaving a profit of \$1,534,685. Interest increased this to \$1,582,185. Depreciation was \$223,874. Adding the balance from 1912 to the profit, the total is \$2,828,614, of which \$1,491,989 was paid in dividends. Ore and metals on hand were valued at \$797,894 at the beginning of 1914.

RAY CONSOLIDATED COPPER COMPANY

Of the great porphyry copper mines in the United States, the Ray in Arizona is worked only by underground methods, as compared with steam-shovel work at the Chino, Nevada Consolidated, and Utah mines. The report for 1913 contains the following information, in addition to an illustrated description of the methods of mining: The total development

in the areas served by the three shafts was 84,729 ft., about 40% less than in 1912. Ore reserves are estimated at 78,380,966 tons, against 80,656,973 tons at the end of 1912. The limits of all the orebodies have not been defined, either laterally or as to depth, especially in the western portion. Broken ore in stopes amounts to about 5,000,000 tons. Mining costs were 73.23c. per ton, which include coarse crushing and loading this ore into railroad cars, 3.5c., and fixed and general charges. All surface improvements at the mine are finished. Ore mined amounted to 2,366,007 tons averaging 1.72% copper.

At the mill, No. 7 section was completed in January, and No. 8 in October, and a total of 8000 tons per day is now treated in the full plant. There were several important improvements made, resulting in higher recovery. Ore milled was 2,365,296 tons, or 6480 tons per day. The average content of the concentrate was 18.55%, and extraction 66.09%. The cost of milling was 51.93c. per ton. Including the metal in some high-grade ore smelted direct, the output was \$54,158,309 lb. of copper.

Financial results were as follows:

| | |
|---|--------------------|
| Revenue from copper | \$7,847,784 |
| Revenue from gold and silver | 51,936 |
| Net miscellaneous income | 177,974 |
| Total | \$8,077,694 |
| Operating expenses | 5,402,502 |
| Dividends paid | 1,631,504 |
| Surplus after dividends | \$1,043,688 |
| Reserve for bond redemption and depreciation..... | 513,466 |
| Balance | \$ 530,222 |
| Forward from 1912 | 2,227,903 |
| Total at December 31, 1913 | \$2,758,125 |

UTAH COPPER COMPANY

The area of mineral lands owned by this Company amount to 736 acres, also 6030 acres at the millsites, Bingham Canyon, and near Utah lake. During 1913, underground work in the original Boston claims totaled 24,812 ft., making a total of all underground development of 439,503 ft. Of this, 309,797 ft. has been rendered inaccessible by surface and other operations. [During March 1914, all underground mining was permanently stopped.—Editor.] Development drill holes totaled 10,153 ft. Underground development cost 1.59c. per ton on the total tonnage of all ore mined by stoping and steam-shovels. The cost of churn-drilling was 0.75c. per ton, so all development cost 2.34c. per ton. The depth of fully and partly developed ore is now 444.5 ft., against 424.3 ft. in 1912. Ore reserves are estimated, according to this depth, as 361,220,234 tons, averaging 1.59 and 1.15% copper respectively. The average thickness of overburden on the orebody is 114 ft. The amount of capping removed was 4,835,479 cu. yd., and 22,125,207 to date. Of the ore mined in 1913, steam-shovels recovered 91.02%, and underground mining 8.98%, compared with 77.81% and 22.19% respectively in 1912. The cost of steam-shovel work was 29.26c., and underground mining 69.52c. per ton.

Ore treated at the Magna and Arthur mills was 4,142,700 and 3,376,692 tons respectively, an increase of 1,516,171 tons over the previous term. On low-grade ore the combined capacity of the plants is 24,000 tons per day; but on average grade ore, the economical capacity is 21,000 tons. The average copper content of the ore was 1.25%, and recoveries at the Magna and Arthur plants 63.78 and 64.18%. The average cost of treatment was 36.76c. per ton. In September this was 30.83c. Concentrate averaged 17.31% copper, and the production was 119,339,809 lb. of metal.

The total cost of mining, transport, and treatment was 97.6c. per ton. Financial results were as follows:

| | |
|---|---------------------|
| Revenue from copper | \$17,063,635 |
| Revenue from gold and silver | 732,583 |
| Miscellaneous | 1,346 |
| Total | \$17,797,564 |
| Operating expenses | 11,494,341 |
| Operating profit | 6,303,223 |
| Dividends on investments | 2,176,000 |
| Interest, rents, royalties | 94,200 |
| Total income | \$ 8,573,423 |
| Interest paid | 60,218 |
| Net profit | \$ 8,513,105 |
| Dividends | 4,747,710 |
| Surplus, after dividends | 3,765,395 |
| For depreciation | 507,712 |
| Balance to undivided profits | 3,257,683 |
| Balance from 1912 | 6,450,970 |
| Balance at December 31, 1913 | 9,708,653 |

Decisions Relating to Mining

DISCOVERY OF LODGE—ADMISSIBILITY OF EVIDENCE

In a suit to determine title and right of possession to a lode mining claim in which plaintiff claimed that there was no well defined lode on defendant's property, which was claimed to be the same vein purported to have been discovered in defendant's discovery shaft, it was held that the court did not err in admitting such evidence and permitting the jury to visit the claim in dispute, where the jurors were duly instructed that such evidence should be considered solely on the question as to whether there was mineral-bearing rock found in defendant's discovery shaft.

Specie Payment Gold Mining Co. v. Kirke (Colorado), 139 Pacific, 21. March 2, 1914.

OUTCROP DEFINED JUDICIALLY

Outcrop is defined as the "edges of strata which appear at the surface of the ground"; "that portion of a vein appearing at the surface"; "the portion of a vein or strata emerging at the surface or appearing immediately under the soil and surface debris"; in general, "that part of a mineral strata that lies at or near the surface of the earth." At what point, at what line—from the outer edge of the strata, which necessarily retreats in progression, beneath the earth's surface—it can be said that the outcrop ends, the term "outcrop" alone does not define or describe.

Sloss-Sheffield Steel & Iron Co. v. Payne (Alabama), 64 Southern, 617. February 12, 1914.

OIL LEASE—FORFEITURE DENIED

An oil lease was granted upon consideration of \$1 and 10% royalties for a term of 20 years and as long thereafter as oil, gas, coal, or minerals were found in paying quantities, the lessee to commence a well within 30 days and complete it to a depth of 300 feet. The lessee drilled one well, pumped the oil, and paid royalties on the output, drilled two other wells which were failures, and stopped operations. Held, on a suit to cancel the lease that it could not be declared forfeit, the lessee's operations having constituted a sufficient performance on his part.

McAffee v. Grubb (Texas) 164 Southwestern, 925. March 7, 1914.

LODE WITHIN PLACER—PROOF REQUIRED

In a suit by a placer patentee in Montana to quiet title against an alleged location of a lode within the boundaries of his claims, it appeared from the location certificates introduced in evidence that the lode claims had been located long before the placer patent was applied for. No evidence, however, was introduced by the lode claimant to show whether or not there had been an actual discovery or whether the lodes contained mineral of such extent and value as to justify expenditures for the purpose of extracting it. Held, that in the absence of such showing decree quieting title of placer patentee was proper. Where mining claims which have passed out of the hands of the original owners have stood unchallenged for years, and have been developed to a considerable extent, the certificate of location, if in due form, may be deemed presumptive evidence of discovery and of a valid location. But in the absence of such grounds for inducing a presumption in favor of the integrity of the location, it is held that the location notice is, when recorded, *prima facie* evidence only of what the statute requires it to contain and which is therein sufficiently set forth.

Thomas v. South Butte Mining Co. (Montana) 211 Federal, 105. February 2, 1914.

Recent Publications

U. S. Geological Survey Publications, Washington, 1913:

SOME ORE DEPOSITS IN NORTHWESTERN CUSTER COUNTY, IDAHO. By Joseph B. Umpleby. Bulletin 539. P. 104. Ill., maps, index.

INTERPRETATION OF ANOMALIES OF GRAVITY. By Grove Karl Gilbert. Professional paper 85-C. Part 'C' of 'Contributions to General Geology, 1913.' P. 37. Map.

THE SAN FRANCISCAN VOLCANIC FIELD, ARIZONA. By Henry Hollister Robinson. Professional paper 76. P. 213. Ill., maps, index. This district covers about 3000 sq. mi. in the north-central part of the state.

MUD LUMPS AT THE MOUTHS OF THE MISSISSIPPI. By Eugene Wesley Shaw. Professional paper 85-B. Part 'B' of 'Contributions to General Geology, 1913.' P. 27. Ill., maps. The peculiar formation of these lumps, containing gases, is described.

THIRTY-FOURTH ANNUAL REPORT of the Director of the Survey, George Otis Smith, for the year ended June 30, 1913. P. 183. Maps. This report covers the work done during the period, and as the ramifications of the Survey and its publications are so well known, no extended notice of this book is necessary.

THE CIRCLE QUADRANGLE, ALASKA. A geologic reconnaissance. By L. M. Prindle. Bulletin 538. P. 82. Ill., maps, index. In the preface, Alfred H. Brooks briefly describes previous work done. This quadrangle contains about 17,000 sq. mi. of well known territory, and includes the Birch Creek placer district, which is the most important.

BIBLIOGRAPHY OF NORTH AMERICAN GEOLOGY, 1912. By John M. Nickles. Bulletin 545. P. 192. Includes publications bearing on the geology of the Continent of North America and adjoining islands, also Panama and the Hawaiian Islands. These total 1275 papers. The indexes include a classified scheme of subject headings, lists of rocks and minerals mentioned, and the geologic formations described.

THE NOATAK-KOBUK REGION, ALASKA. By Philip S. Smith. Bulletin 536. P. 160. Ill., maps, index. In the preface, Alfred H. Brooks describes what is known of an area of 150,000 square miles of the territory above the Arctic Circle. The Noatak River region is around 68° latitude north. The mean annual temperature is about 16.5°, ranging from -31.3 to 60.8°F. Game and fish are fairly plentiful. Quartz veins are numerous, the older being in schists and limestones. About \$100,000 has been recovered from gravel in the Shungnak region. The other river deposits are described. Copper ores are also found. The cost of supplies and operations will not decrease materially in the future; but observant prospectors, properly equipped, may find the country worth investigation.

MINERAL FUELS. Contributions to *Economic Geology*. Bulletin 531. P. 361. Ill., maps, index. The subjects deal with petroleum and natural gas, and coal and lignite; prepared by the following authors, Marius R. Campbell being geologist in charge: M. J. Munn, R. H. Wood, E. G. Woodruff, G. H. Ashley, M. R. Campbell, F. A. Herald, G. S. Rogers, J. T. Pardee, C. F. Bowen, C. H. Wegemann, W. T. Lee, J. H. Hance, and A. J. Collier.

California State Mining Bureau publications, San Francisco, 1913 and 1914:

MINERAL PRODUCTION OF CALIFORNIA, 1912. Compiled by E. S. Boalich. Bulletin 65. P. 64. The total value of all minerals produced was \$88,972,385, of which gold contributed \$19,713,478 and petroleum \$41,868,344.

MINING LAWS. Bulletin 66. P. 89. Covers certain federal laws and those made by the state legislature.

Industrial Progress

THE ALBERGER PUMP & CONDENSER Co. has issued bulletin 19, descriptive of Alberger expansion joints.

ABENDROTH & ROOT MFG. Co. announces a change of address from 50 Church street to 45 Broadway, New York City.

THE LANE MILL & MACHINERY Co. is distributing a new catalogue, No. 7, descriptive of the Lane slow speed Chilean mills.

JOHNSON ELECTRIC SMELTING INC. has been formed to acquire the patents and business of the Continuous Zinc Furnace Company.

THE DENVER ENGINEERING WORKS Co. has published a special description of the Isbell concentrator, which is now sold by that firm.

THE SPRAGUE ELECTRIC WORKS is sending out now bulletin 41010, containing details of the Sprague direct current motors, types, 'C' and 'D'.

THE FRED M. PRESCOTT STEAM PUMP Co. has published bulletin P-105 containing descriptions of the Prescott, duplex, power-driven, mine pumps.

THE HARDINGE CONICAL MILL Co. reports a repeat order for two 8-ft. Hardinge mills from the Spassky Copper Co. The original order included nine sizes but the 8-ft. mill has been adopted as standard.

FAIRBANKS MORSE & Co. is distributing bulletins 27 and 29 descriptive of direct current, commuting pole, motors and generators, types 'CP' and 'TRC'; Bull. 210 dealing with internal starter motors; and 202H, standard induction motors.

THE ROBINS CONVEYING BELT Co. has issued a circular letter of warning regarding infringement of its patents. It is stated that confusion has apparently arisen from the fact that one of the patents of the Company has expired, though this leaves all the essential features of the devices now manufactured, fully protected.

THE INGERSOLL RAND Co. announces the opening of a branch office at 1036 Union Oil Bldg., Los Angeles, which will be in charge of W. A. Townsend, formerly at El Paso where he is succeeded by J. D. Foster. At Juneau a branch in charge of Frank Carroll has been established, and at Pittsburgh Walter A. Johnson succeeds C. F. Overly, who goes to Cleveland, Ohio.

The Diesel Engine

The Busch-Sulzer Bros. Diesel Engine Co. has prepared and is distributing a most attractive and valuable handbook on the Diesel engine as developed in America. It is not generally known that Diesel engine construction began in the United States in 1898, only a year after Rudolf Diesel completed his first successful engine at Augsburg, Germany. Adolphus Busch was attracted to the matter while in Germany, and, securing the assistance of E. D. Meier, he built at St. Louis, in 1898, the first American Diesel engine, which by the way is still in operation and doing good work. Since then there have been many improvements and business changes, but from this beginning has grown the business which has spread over the whole country. The fundamental economy of the Diesel principle, which permits a thermal efficiency of 32 to 35%, was bound to make the engine successful, and it has done so. One needs but to look at the pictures illustrating the wide applications already made to realize the possibilities of the future. These pictures, with the concrete facts as to efficiency and economy presented in this book, made it clear that the matter is one of first importance to power users everywhere.

EDITORIAL

LABOR camp sanitation is treated concisely but informally in a pamphlet issued by the Commission of Immigration and Housing of California. Copies may be obtained upon application to the Commission at 525 Market street, San Francisco, and are well worth having. Better quarters means more contented and efficient labor; also, in California, it may mean avoiding a fine.

DEVELOPMENT of a skilled staff for its new enterprises has been taken in hand by the Standard Oil Company, and many of the graduates of technical schools have been engaged to take a summer course in business and instruction, after which they will be sent to China on a contract at a very satisfactory salary. The opportunity is one which adventurous young men would naturally grasp at, and the chances for achievement somewhat parallel those on our own frontiers of some decades ago.

CHISANA placers are not developing the bonanzas which were anticipated a year ago. The latest reports are very skeptical as to what the future of the district will be and indications are far from encouraging. The old workings on Bonanza and Little Eldorado creeks are the only producing properties and no new discoveries of importance have been reported. Bowen creek is attracting some attention at present and is the most promising part of the district. Hopes are expressed that the spring operations will result in renewed activity, but optimists are few, and it is generally believed that Chisana will never be classed among Alaska's large gold districts.

RAILROAD VALLEY COMPANY, which has spent \$150,000 in prospecting for potash in Railroad valley, Nevada, has given up hope of finding this salt in profitable quantities. The last hole, which reached a depth of 1122 feet, gave negative results, and the Company will now devote its attention to further exploration of the gaylussite beds which were discovered in the course of the work. The geology of the district is most interesting through its association with the dry-lake theory of potash deposition, which subject was discussed by Mr. E. E. Free in our issue of August 2, 1913. While exploration has not proved the presence of potash to warrant exploitation, the gaylussite beds are of possible commercial importance.

THE Reinohl process of rapid cyanidation, a so-called new process of extraction, is, as is usual, being heralded with figures which savor of imagination rather than fact and with no very clear evidence in the literature distributed to prove the contentions. The mining public has become extremely skeptical of such statements as "the installation cost of the new process will be only 50 per cent of modern cyanide plants, labor charges will be reduced 25 per cent, cyanide consumption 50 per cent, and the extraction will be 95 to 100 per cent," etc. Such figures carry more weight if published in detail by a disinterested person after a plant has been installed and in operation for a reasonable length of time. Such statements, published for promotion purposes, only tend to discredit what may be a process of merit. We would like to accept them, but literature of this nature, which is apparently founded largely upon theory and imagination, is worthy of the waste-paper basket only, until actual figures are available.

ALL waste is deplorable, but the waste of human life is criminal. We have been curiously inconsistent in our thinking on this topic. The shooting down of a man on the public streets attracts widespread attention and is universally recognized as a crime, but the death of a workman who has been set to varnishing tanks without being told that the fumes of wood alcohol are deadly, has in the past been considered merely an accident. The president of a company, who would not for a moment think himself entitled to borrow a club member's racquet and return it to him with the strings broken, has too often thought himself entitled to employ some poor woman's son and return him to her with limbs broken or health shattered. Happily a new spirit now pervades the industrial field, and on another page Dr. J. W. Luther, chief surgeon for the New Jersey Zinc Company, interestingly describes the effective work which may be done for safeguarding the health of the worker when the organization which employs labor is sufficiently large to bear the overhead cost of such an organization. Work of this sort pays the best kind of dividends.

American Investments in Mexico

The question as to what will become of American investments in Mexico in the event of intervention has been the subject of a great deal of comment in this country, and fear is expressed by many that all American property within the confines of Mexico will be razed in the event of war. This opinion is largely the result of the much advertised anti-American feeling among the Mexican people, which in reality exists for the large part in the minds of American newspaper writers. American, together with all foreign and native investments in Mexico, are suffering as a result of the present conditions, and it is only with

the reestablishment of peace that any change may be expected. It is gratifying to note, however, that even where it has been necessary to completely suspend operations, foreign property has been generally respected in both Constitutional and Federal territory, and where looting has taken place it has been invariably by outlaws. Mining property has been abandoned in many instances, but in most cases operations can be resumed immediately after transportation is reestablished and local conditions will permit. The railways have been the greatest losers as a result of the present trouble. It is estimated that American investments in Mexico amount to \$1,057,770,000; of which investment \$223,000,000 is in mines and \$643,000,000 in railroads. English property is valued at \$321,302,800 and the Mexican investment totals \$793,187,000.

The smelter property of the American Smelting & Refining Company in Mexico is valued at \$10,000,000, while the surface plants and destructible property at the mines of the Company is valued at between \$3,500,000 and \$4,000,000, according to *The News Letter*. Two of the five smelters, 20 of the 26 mines, and one of the four railway lines are situated in the territory which is held by the Constitutionalists, and are therefore, in view of the stand taken by Villa, believed to be safe from attack. Of the total surface improvements of the Company's property \$6,300,000 is estimated as being invested in Constitutional territory. The smelter plants in Federal territory are valued at \$6,000,000, and in the event of this property being attacked, it is not likely that more than a 60 per cent loss would be incurred, or about \$3,600,000, and the damage to the mining property would not exceed \$1,000,000. This, with a possible loss to railways and expenses incident to the flooding of the mines, would bring the possible loss of the Company due to destruction of property in the Federal states of Mexico to not more than \$5,000,000. These figures are based upon hypotheses which at present seem hardly likely of fulfilment, and are only of interest as to what might happen to one of America's largest investors in the event of a general uprising against Americans in both the Federal and Constitutional territory of Mexico.

We cannot believe that such conditions are within the range of possibility. Mining and smelter property held by foreign interests in all parts of Mexico has been generally respected, and instances of vandalism are comparatively few. Throughout Mexico the mine and smelter operators have in general maintained friendly relations with the communities in which they operate, and from these people, who have been so largely dependent upon foreign investment for a livelihood, little or no apprehension need be felt. The much talked of anti-American feeling in Mexico has been greatly exaggerated. It is true that the student class of Mexico City occasionally give vent to such a feeling by parading the streets, making speeches, and breaking windows and the *pelado* element enjoy following in the wake of the procession lending their voices and making a

holiday of the *demonstracion*. The sentiment, however, is not representative of the whole of the Mexican people, and even when spurred on by the approval of a drunken dictator, we doubt if any material damage would result to American property. *Mueren los gringos* is a popular slogan with the student class, as it has proved effective in more than one instance for starting a *bola*, as the Mexicans say, but when it comes to the actual killing of American citizens or the wanton destruction of American property, there is yet to be recorded such an outbreak as the result of anti-American feeling. Americans have been insulted in the streets of Mexico City and windows in American establishments have been broken, but this has been the extent of the violence. The loss of American lives and property in Mexico may be almost wholly attributed to bandits and outlaws, whose sole purpose has been to plunder and as such have been no respecters of persons or nationalities.

Lead Production and Future Prices

Comment has been excited recently by the fact that among the metals, lead is the one most unresponsive to change in price. Comparing the production and price of lead for recent years, it may be noted that since 1875 the domestic output of lead has increased eight times, from 50,000 tons per year to over 400,000 tons per year. There has, however, been no consistent change in prices. For example, in 1880 the average New York price was 5.04 cents, and in 1896 it was 2.98; but the highest average yearly price for the entire period was realized in 1906. During that year and the first half of 1907 the average weekly price of lead in New York was between 6½ and 7 cents per pound. The business crisis in the autumn of 1907 carried the price down to 3½ cents per pound before the end of that year, and for a few months the market was only sustained by the disposition of the farmers to give their houses a new coat of paint. By the following July the price had risen to 4½ cents, near which figure it remained until the autumn of 1912, when it rose to 5 cents for a little while, soon declining to below 4½ cents. Last autumn the price rose slightly for a brief period and has since generally declined, being now below 4 cents per pound at New York. This would not by itself be remarkable, but another fact must be considered. Though the domestic output of lead has been steadily increasing in the past thirty-five years, no new lead deposits of any importance have been developed in the United States, or indeed, until within the past year or two, anywhere in the world. Here we have two apparently diametrically opposed sets of facts: increasing output from a limited supply, and a stationary or declining price. From these premises only one deduction is possible, namely, that the industrial world views with equanimity the possibility of having to get along without lead. Belief in this view is strengthened by the fact that the world's output has,

in the past five years, only shown an increase of 13 per cent.

Evidently the consumption of lead is on the wane. But in surveying the field it is hard to detect any great source of weakness in the lead market other than the depressed state of general business since 1907. It is true that lead pipe is largely going out of use in plumbing work, nicked iron being used for exposed plumbing and plain iron for covered work. On the other hand, the consumption of lead for covering electric cables has greatly increased in recent years. Probably the consumption of lead pigments for paint has also decreased, as zinc has cut into the field and there is a tendency to use a mixture of paint bases rather than lead alone. Even more important is the tendency toward the use of fireproof construction. The wooden house, painted white with green shutters, has gone out of fashion and cement or stucco houses, their interiors and exteriors colored by the use of ochre or other mineral pigments, are the prevailing style. The aggregate effect of such factors is tremendous, doubtless serving to explain why the lead market remains persistently weak while the future output of the metal seems so limited. Quite recently another factor has intervened to aggravate the situation. In the well known Burma Mines, Limited, large orebodies of complex lead-zinc ore have been discovered, and, as we recently have noted, even larger orebodies of somewhat similar nature have been developed in southern Siberia, with the possibility of more to come. By present metallurgical methods these ores can scarcely be worked at a profit, but it is hoped that by smelting in the electric furnace, both zinc and lead can be recovered at a good operating profit. In this case, the world's supply may be considerably augmented. However, the trend of events in the past nine months has been rather toward the export of lead, a condition which has not prevailed in many years. General business has been dull in this country, and although the total output in this country has slightly declined in the past three years, the price has declined, as already noted. The London price, on the contrary, has shown a tendency to increase since the first of last year, and in December 1913 was actually above the New York price in spite of the present duty which tends to maintain the domestic price at a fairly steady level above the London price. The present critical situation in Mexico further constricts the European supply, and as the new foreign lead already mentioned is still some distance in the future, it may be expected that, for a while at least, the European lead market will be strong and the domestic lead market weak. The outlook, on the whole, seems to be that the consumption of lead is not likely to continue strong enough to force up the price of the metal. In short, lead, as compared with other metals, is in much the same situation as the horse compared to the automobile; for many uses it will retain a permanent place, but the tide of development seems to be turning in other directions.

DIAGRAM SHOWING WORKINGS OF PERSEVERANCE MINE.

Preparatory Work of the Alaska Gold Mines Company

In an excellent report, accompanied by large half-tones and mine plans, the Alaska Gold Mines Company reports that the following work was done in 1913:

The president, Charles Hayden, states that the Company owned on December 31, 1913, \$3,267,500 par value of the \$3,500,000 bonds; and \$11,299,845, par value, of the \$12,000,000 stock of the operating company, the Alaska Gastineau Mining Co. It is not the intention of the management to make large expenditures at the present time in further developing the veins already disclosed, as the extent of ores now opened is deemed amply sufficient upon which to formulate operating plans. The cash in the bank on December 31, 1913, was \$1,740,750.

The vice-president in charge of operations, D. C. Jackling, reports as follows: Progress in development and construction throughout the past year was satisfactory in every way.

The principal group of mining claims is situated about three miles in an easterly direction from the town of Juneau, and covers the Gold Creek lode system of gold-bearing veins for a length of over two miles.

Mining

The lowest working shown in the accompanying plan is the Sheep Creek adit, which has been driven for the double purpose of further developing the property, both longitudinally and at depth, and to serve as a transportation outlet for delivery of ores to the new mill. This, on account of the importance of its early completion, took precedence over other development work during the year. The total length necessary to be driven from the portal of the adit near Sheep creek, to the bottom of the Perseverance shaft, is approximately 10,000 ft. During the year this adit was advanced 6431 ft., or at the rate of about 536 ft. per month. The advancement during the early part of the year was not so rapid on account of inadequate air-supply for machine-drills. For the last six months of the year the average distance driven monthly was 583 ft. For three of these months the advancement was over 600 ft., and in November 661 ft. was driven. This adit is driven parallel to and

in the foot-wall of the principal or Perseverance vein; but on account of the desirability of completing it as rapidly as possible, so that it can be equipped and available for use, not only for delivery of ores when the mill is ready, but for ventilation and the transportation of supplies prior to that time, it was not considered advisable to delay its progress by cross-cutting for the development of ore.

During the year the sinking of No. 1 shaft was completed to the Sheep Creek or No. 13 level, and it was enlarged to the surface. The total depth of this shaft is 1544 ft. Development on the vein in preparation for mining was continued on most of the proposed levels above the Alexander or No. 10 level. The extent of this work can be observed from the accompanying plan. It will be seen that No. 10 level has been extended to a total length along the vein of nearly 5000 ft. Throughout this distance the ore deposit has been developed by frequent cross-cuts and found to be substantially uniform in size and value. These characteristics have also been proved by numerous cross-cuts on other levels, and, as previously stated, the Sheep Creek adit has cut portions of the vein longitudinally at a few points throughout its course, this occurring more frequently under the easterly end of the mile-long zone developed on the No. 10 or Alexander level. The height of vein measured on its dip above the Sheep Creek adit and for the length of zone developed on the No. 10 level is nearly 2000 ft., and as previously stated, the length of zone so developed is about 5000 ft. The thickness of the main vein that has been used for previous estimates of tonnage and which may still be used conservatively, is 70 ft. A solid block of ore having the given dimensions would contain considerably more than 50,000,000 tons. It cannot be said that an orebody of this size has been fully developed, but nevertheless all of the underground work, including a large number of diamond-drill holes through the vein, taken together with extensive samplings both underground and on the surface, indicates a uniformly increased thickness of commercially valuable orebodies, as compared with that used in previous estimates and prevailing throughout

much greater lengths and depths on the ore deposit than those stated above. Furthermore, an entirely new orebody has been developed to the north of the main Perseverance vein, on No. 5 level, which is being opened for mining. At the time of writing this report, this development has extended for a length of several hundred feet, showing an ore deposit well over 100 ft. thick. In addition to the disclosures as described, on and adjacent to the main vein, substantial consideration must be given to that on No. 2 vein developed by the Alexander adit as referred to in the last annual report, and situated about 2000 ft. north of the principal vein series. The vein has been prospected for a length of over 600 ft. as indicated on the accompanying map. Its thickness is over 100 ft., and a mill-run sample of several hundred tons taken from across this full width showed a gross value of about \$1.60 per ton, or about the same as the recoverable value estimated for the ores of the principal vein series at the time the enterprise was undertaken. On the whole, there is every assurance that the tonnage of ore of commercial grade ultimately available from the property will be vastly in excess of any definite estimates heretofore or now made.

The total amount of development work done during the year, including that of the Sheep Creek adit, the main shaft, and other work such as drifts, cross-cuts, etc., but not including diamond-drill work, was 22,137 feet.

The surface improvements at the mine include substantial, commodious, and comfortable quarters for all of the mine employees who will be required when operating at the full capacity of the mill now under construction. A new compressor plant was constructed to accommodate two 3000-cu. ft. electrically driven compressors, which will furnish all the air the mine will require for the output now contemplated.

Power Supply

The development and equipment of the Salmon Creek water-power provides for a continuous year-round production of 6000 electric horse-power. In order to secure this output it is necessary to store some of the floodwaters in the summer time for use in balancing the supply during winter months, and therefore an essential part of the development is the construction of a reservoir, which made necessary the building of a concrete dam 165 ft. high and 700 ft. long on its crest. In order to get the maximum benefit from the total amount of water available, it is necessary to build two power-plants. One of these is situated about a mile from the dam and operated under a head of 600 ft. The water discharged from this upper power-plant, together with a considerable additional amount of water gathered from a drainage area lower than that serving the reservoir, is conveyed by a flume for a distance of about 10,000 ft. and used under a head of 500 ft. through another power-plant of similar design situated on the shore of the Gas-

tineau channel, near the mouth of Salmon creek. Each of these power-plants will be equipped with two 1500-kw. generating units, and will therefore have a total capacity of 6000 kw., corresponding to 8000 horse-power.

Milling Plant

The work in this division comprises the construction of a reduction plant having a capacity of 6000 tons per day, together with the necessary accessories. In this division is also included the construction of a narrow-gage railroad in and from the Sheep Creek adit to the mill-site, for the transportation of ore. All portions of the mine above the Sheep Creek adit will

DUMP AT PERSEVERANCE MINE.

connect with it by chutes through which ore will be drawn into cars of about 10-ton capacity and hauled by electric locomotive in trainloads of about 300 tons to the coarse-crushing plant situated some distance above the main concentrating building. Here the ore will be dumped, crushed, and discharged into large underground storage-bins, from which it will be drawn to conveyors, and by them delivered to the main concentrator at a point about 300 ft. lower in elevation than the coarse-crushing department. This coarsely crushed ore will be received in the fine-crushing department at the upper part of the concentrator, and at an elevation of approximately 150 ft. above the lower floor of the mill, thus providing sufficient elevation between the upper and lower part of the mill to permit of its operation almost wholly by gravity, and contemplating the minimum use of elevators. The lower floor of the mill is approximately 200 ft. above tidewater, thus providing ample elevation for the disposal of tailing. During the year, actual grading for the coarse-crushing plant and concentrator was commenced, and about two-fifths finished before the end of the year. At the time of writing this report the grading for the coarse-crushing plant is entirely completed and that for the concentrating plant practically so. Concrete foundations have also been completed for the coarse-crushing department and commenced for the main concentrator. The structural steel for the coarse-crushing plant is practically all on the ground and will be in process of erection before this report is published.

Copper Matte Production in the Reverberatory Furnace

By HERBERT LANG

Remarkable progress has been made within the last two decades in the art of making copper matte in both the blast-furnace and in the reverberatory, especially in the latter, which has been the subject of much discussion. The surprising records of the big reverberatories which have been erected within the last few years have been the subject of many press communications and accounts in the technical papers, often accompanied with illustrations and statistics of importance. The various innovations in reverberatory construction and management have been fully described, especially the former, and it may seem that the subject has been sufficiently touched upon. There are, however, several matters of principle which, it seems to me, merit further consideration.

Long Reverberatories

It has often been said of late years that the chief improvement in the reverberatory has been in its increase in length; as if this increase were not necessarily attended by variations in its practical working. The fact is that the lengthening of the furnace has brought about, or rather made possible, a great improvement in practice, by which the performance has been enormously bettered. Not only has the daily duty been increased in correspondence with the enlarged hearth area, but the perfection of the smelting has been brought to a par with that of the well conducted blast-furnace, of which it has always in some measure been a rival. The tendency of these improvements, therefore, is not simply toward an increase of capacity, but largely toward better work. These and associated matters will be considered in the following discussion.

In order to understand thoroughly the line of development of the reverberatory copper-smelting furnace, it will be convenient to consider the former style used first in Swansea, Wales, or copied from that original. Swansea was the primal home, or at least the cradle of the reverberatory, records showing that it has been in use there for a continuous period of three centuries and more. It is not a little remarkable that during so prolonged an experience the furnace was never improved to any notable extent. It will be remembered by some, no doubt, that Vivian in his little treatise on copper smelting published in 1880 (a period which now seems historically ancient in this art), remarked that the charges used in his time varied little in weight, and probably in composition, from those used by the smelters in the time of Elizabeth, to which period he traces back the English practice of copper smelting. They had not, accordingly, enlarged their furnaces appreciably during all that time, nor, so far as I can learn, had they im-

proved to much extent the quality of the metal produced. This is very curious, and leads to a train of (unprofitable) moralizing with which I need not trouble anyone. The main thing to remember is that the furnaces had not outgrown the traditional size, nor had the art outgrown the traditional management. So late as Vivian's and LePlay's time, men were still engaged in 'packing' ore on their backs in the works of Swansea, and except for the tremendous stimulus given to this branch of metallurgy by American practitioners, they would probably still be doing the same. Modern English metallurgy, however, has become a very different thing, and although we may enjoy 'taking a fall' out of our British compeers, it is not fair not to acknowledge that they are rapidly catching up with the procession. The ancient British practitioner must have considered the art of smelting as a gift of Providence rather than something to be acquired, and I can fancy him saying in his customary vernacular: "L'arn it! Yer earn't l'arn it. It's a bloom-in' gift!" Else we had not borrowed the Swansea type of furnace, perhaps. However, it was an Englishman, Pearce, who, under the stimulus of American conditions, first set about enlarging and improving, at the Boston & Colorado smelter, at Black Hawk, Colorado, the little Swansea reverberatories with which work had there been begun.

Early Practice

The original reverberatory consisted, to outward view, of a rectangular box of brickwork, about 20 ft. long by 10 ft. wide and 6 ft. high, surmounted by a flat arch, and containing within an elliptical space of about 15 ft. long by 9 ft. high in its greatest width, and of a height averaging three feet or thereabouts. This space was connected at one end with a fireplace, and at the other with a smoke flue, and was provided with doors on one or both sides and at one end, for the introduction of the charge and for the handling of tools for repairs, etc. The fuel at Swansea was coal, but dry wood at Black Hawk. About one and a half tons of ore was smelted with a ton of coal, while at Black Hawk a cord of wood smelted one ton of ore or a little more. Wood is not a very good fuel for the reverberatory, not giving enough heat, and requiring too much attention during combustion, with too frequent opening of the fire-doors. Coal, of course, is good, if it be the right kind, giving a long flame, but the ideal fuel is petroleum. This fuel requires little attention, and the heat is ample and easily controlled.

The cycle of operations at one of the little furnaces was as follows: The furnace being empty, the charge, composed of the crushed ore, reduced in size to pass a

1-in. ring or generally smaller, mixed with the appropriate fluxes (of which only small quantities were ever used, and frequently none at all), was brought to the furnace and dumped on the floor near the side door, which covered an opening from 1½ to 2 ft. wide. This being opened, men shoveled the material into the elliptical space (the hearth), taking care to spread it evenly. It formed a layer some six or eight inches deep. This done, the door was closed and luted up with clay to prevent the influx of air, which has a cooling effect, of course. The fire was then replenished, it having been allowed to go down at the end of the previous operation, and the charge was heated up as quickly as possible, the greatest practicable amount of fuel being burned during the period of fusion. Unlike modern practice, the charge was cold and began to smelt very slowly. The slag and matte remained practically in the spot where first formed, displacing the ore gradually from its bed by sinking beneath it because of their greater gravity. The charge, varying from two and one-half to four tons, might average three tons in weight. If so, it would give rise, ordinarily, to perhaps two tons or 20 cu. ft. of slag, and three-fourths of a ton or 5 cu. ft. of matte. These quantities, infantile in the modern conception, varied, of course, according to circumstances, but may be taken as an average of the practice of ages.

Fusion in Furnaces

Fusion takes place in a reverberatory in a peculiar manner. The ore may be practically all melted, but the slag will remain non-homogeneous and stiff, requiring a further exposure to heat to thin it to the point at which it may be run out or be skimmed out properly. Unfused fragments, especially of difficult fusible substances, remain for a long while floating about, and as long as they come into contact with already melted stuff of a different composition there will ensue reactions which give rise to the evolution of gas, or to the fresh formation of matte, which will require additional time to settle out of the bath. Settling of the matte quite out of the slag is, of course, a *sine qua non*, since, no matter at what time it be formed it will contain metal of value. To remove (skim) the slag before the matte has settled from it is equivalent to a large waste, notwithstanding the time that may be saved thereby. Accordingly, a period of some length, even to an hour, is allowed to pass while the firing is kept up. This is to be particularly borne in mind since in the doing away with this time of waiting is one of the great modern improvements in this kind of smelting. At the end, when the molten mass had become quiescent, indicating the end of the reactions, the front door was opened and the slag skimmed from the surface of the matte. It ran into cavities scraped in the ground or perhaps into cast iron molds placed in a row, whereby a dozen or more cakes were formed, which after cooling and hardening were removed by hand and cast upon the dump, excepting the

cake nearest the furnace, which contained in general too much matte or ore particles to allow of its being thrown away. This cake was usually broken up and returned to the furnace. The matte, cast in similar cakes, was also taken away, to be subjected to further treatment by roasting and re-smelting. All this involved much hand labor. The furnace, now empty, invariably needed repairing, especially the material of the hearth and sides, which, due to erosion caused by the contact with the melting ore, commonly of a nature to unite with the material of the firebrick and sand, was usually much eaten into in spots. I may say here that the matte, in Swansea practice, was usually granulated by being allowed to run molten into water, which breaks it up into minute granules. The object is to save the expense of crushing previous to roasting, the operation next in line. Matte and slag both granulate freely in water, but are somewhat difficult to dry afterward. For this and for other reasons, in particular the danger of the operation, the granulation of matte is not commonly practised.

Accumulation of Matte

The first improvement of significance consisted in allowing the matte to accumulate on the hearth during the smelting of several charges, instead of tapping it out after every charge. This was first done at Black Hawk, where the ores were of such a character as to give rise to but a small proportion of matte. Here the tapping took place but once a week, as a rule, and the matte was very rich in the precious metals. It was discovered in this way that the hearth was better protected from corrosion, having the large body of matte over it by which air was excluded, and furthermore the charges were more easily spread, in fact they spread themselves mainly, as when dumped upon the molten bath they had a strong tendency to float outward to the borders of the hearth. This discovery led to another improvement, that of feeding the furnace from hoppers placed above the arch or roof, whereby the whole charge could be quickly introduced, without the opening of the side door, and consequently without the loss of heat and time attending the usual operation of shoveling the charge in. The hoppers were not a new thing, having been used before, but their appropriateness was much enhanced when it became the practice to feed the ore upon a bed of matte. Fine material, when charged in this way, requires no spreading with tools. The pile of ore, without touching the bottom, subsides rather quickly and within a short time forms a layer over the liquid surface and receives heat, as reflection will show, both from above and below. The radiant heat of the burning gases above affords the most, but a considerable reserve of heat in the matte is given up to the ore above; the result being to fuse the charge much more quickly than if spread upon a comparatively cold hearth. The saving of time is, therefore, considerable. Herein lies the advantage of the mod-

ern method of charging from hoppers as distinguished from side charging. The economy of labor is equally apparent. The lengthening of furnace hearths, which began with Argo practice, Argo being the successor of Black Hawk, spread from there to Anaconda and then to the rest of America. Pearce's largest furnace had a length of 35 ft., which was considered enormous for those days, but structures of more than three times that length are the fashion now, and one seldom hears of a new reverberatory less than 100 ft. long. The favorite size is 19 by 119 ft., dimensions reached in Anaconda practice but imitated almost slavishly, as if there were especial virtue in those figures. It will be noticed that the increase in width of hearth does not keep up with length; in fact, the width remaining almost stationary; or, more explicitly, it has increased only to double that of the Swansea type of furnace, while the length has increased no less than eight times. One of the principal reasons for this lies in the difficulty of supporting an arch of greater span, the limit having apparently been reached in the neighborhood of 20 ft., while, of course, no difficulties are encountered in increasing the length.

Matting Furnaces

Reverberatory matting furnaces perform two principal functions, namely, the fusion of the materials and the separation of the two molten products, the matte and the slag. These take place coincidently to a great extent, but it is found that a considerable quantity of matte, in the form of fine drops termed 'prills', remains in suspension even in very fluid slag for quite a time, requiring for complete separation that the substances remain in the liquid condition throughout. To effect this, it would be quite feasible to attach a settling hearth to the furnace, as is done in blast-furnace matting, in which the mixture would have an opportunity to separate, or to provide a second furnace, kept hot by its own fire, into which the fused material could be tapped, and in which the separation could go on slowly. Either method would improve the percentage of extraction, and by shortening the cycle of the primary furnace, would conduce to more rapid running. But the same end is achieved by merely lengthening the hearth, giving ample opportunity both for fusion and separation. These long furnaces are virtually combinations of furnace and settling basin, the interior space not being given up wholly to the smelting, but a good part of the length being reserved for the separation. The part devoted to fusion, being that next to the firebox, is about one-third of the length. Upon this the ore is charged; after melting, it flows toward the other or flue end, and, still remaining at the fusion temperature, finds ample opportunity for the subsidence of the matte particles and for the conclusion of the reactions upon which the success of the work depends. There is opportunity also for the complete intermingling of the slag, which thereby attains a degree of homogeneity

not found in the product of the older furnaces. 'Floaters,' which are undecomposed silicious remnants of the charge, are formed in the modern reverberatories as they were in the ancient ones, but they have more ample opportunity to dissolve and mingle with the slag, which they will do if there be unsaturated bases to combine with.

The type of slag made in the modern reverberatory is perforce of a fusible kind, neither very acid nor very basic, but best described as neutral. It does not differ in the balance of its constituents from ordinary blast-furnace slags. The great capacity of the modern reverberatory, reaching into hundreds of tons daily, demands special and effective methods of getting rid of the slag formed in such vast quantities. The antique practice of charging, hit or miss, anything that would melt, wholly or partly, into a heterogeneous and oftentimes viscous slag, which was either skimmed or dragged from the furnace, according as to whether it was melted or only floated, is inapplicable to modern works, which demands an entirely liquid product, capable of flowing out of the furnace without being urged by the tool. Those silicious slags represented in Swansea practice, one-third of which was composed of unmelted fragments of quartz, could only be removed from a furnace by manual force, and could not be handled on a large scale at all. To get 300 or even 100 tons of such stuff out of a furnace would require that the skimming door be kept open all the time. Such proceedings have given way to the practice of calculating the composition of the slag as closely as is done in blast-furnace work, keeping the silica and bases in proper proportion to form a fusible and not too dense a slag, which flows out readily when the door is open, and leaves the hearth clear in ten or fifteen minutes, without the use of tools. Here, also, is a great saving, the labor account being much diminished beyond former practice.

Movement of Slag

It will be observed that the movement of the slag within the furnace is in the main from the firebridge to the skimming door at the other end of the structure. In order to utilize the full length of the hearth for the purposes indicated, the furnace must be skimmed at the extreme end, rather than from doors situated upon the side, as was the frequent practice in former days. The matte tap, however, still keeps its place on one side, about midway of the hearth, and the method of tapping and disposing of that substance has not changed appreciably, excepting in the well grounded improvement of keeping a thick bath of the molten stuff upon the hearth, to buoy up the fresh charge. From this has been evolved the practice of tapping only a comparatively small portion at once, the aim being to preserve a certain depth at all times. The slag need not be cleanly skimmed at any time, since the retention of a thin layer to receive the fresh charge is not at all prejudicial to the process. In

fact, the aim generally is to keep the liquid surface at approximately the same height at all times, thus avoiding unnecessary exposure of the brickwork to the heat and the fluxing action of the charge.

Hearth Foundations

The vault beneath the hearth, once deemed indispensable, has been given up, and reverberatories are now universally built with solid bottoms. The cooling effect of the open space, designed to prevent the penetration of the matte, has been proved prejudicial, since it involves a considerable loss of heat from that part which needs it most, namely, the hearth, and the temporary loss of metal cuts no great figure in large operations. The hearths are now invariably made of sand as formerly, the brick bottoms advocated some years since not having attained extensive use. Perhaps as much improvement has been made in materials as in forms of construction. The chemistry of brick-making is now thoroughly understood, and there is no reliance upon rule of thumb. The composition of the materials for different uses, as of silica brick for the arch, neutral ones for the inwalls, and silica sand for the hearth, have received ample consideration, with the result that almost all of the bugbears of the former age have been killed off and smelting reduced to a science. Further, the application of chemistry to the composition of the charges and of the refractory materials composing the furnace itself has brought about and maintained such conditions that the structure has become much more durable. It was formerly taken for granted that the interior surfaces in contact with the slag had necessarily to be eaten away, the waste being supplied by the copious and regular introduction of the so-called 'fettling', which is a loose aggregate of silicious stuff, as clay and quartz, whose application was a regular and laborious duty. By controlling the composition of the slag, and especially by the use of the right brick in the inwalls, this necessity has largely disappeared, and now we find furnaces running regularly which require repairs only once a month or even less often. This tends very much to economy in running. By thus obviating the causes of delay, the economy of the process has been largely increased.

Innumerable persons, perhaps visiting a smelting works for the first time, and taking note of the intensity of the heat at the flue, or even perceiving signs of fusion of the brick lining of the smokestack itself, accompanied perhaps by flames issuing from the top, many feet away, have inferred a great and unnecessary waste of heat and fuel. I have heard suggestions as to the lengthening or enlarging of the hearth, based on this idea, but although there is a waste of heat, it is not an unnecessary waste. The reason is that the whole working space within the furnace has to be kept at practically the same temperature throughout, in order to do the work of smelting and to keep the slag fluid at all points. Were the flue end of the

hearth appreciably cooler than the vicinity of the bridge, the process could not go on in a practical manner, for the slag would cool within the furnace and cease to flow. It will appear from this that the exit gases, which are necessarily as hot as the interior, must escape into the flue at the full temperature of the furnace and its contents, involving a loss of heat roughly estimated at one-half that due to the combustion of the fuel. One may therefore look upon the reverberatory as a wasteful agent which must lose in the flue alone one-half of the original heat of combustion. By the interposition of regenerators or waste-heat boilers in the flues, the loss of heat is much reduced. The former of these expedients, designed to heat the air for combustion, has not been successful, owing to the clogging of the checkerwork by the dust carried over by the gases; but the latter has achieved great and immediate success, and much power, estimated at above two horse-power for each ton of charge smelted daily, is returned by the steam plant, which, owing to the regularity of the furnace work and the consequent evenness of temperature of the exit gases, runs with as much smoothness as could be desired.

The Firebox

The firebox of a big modern coal-burning reverberatory is as large as an oil-furnished furnace, firebox, hearth, and all. It burns, of course, a great deal of fuel, but it smelts more ore with the same weight. It may smelt, say, 240 tons of charge with 60 of coal, while the older furnace smelted perhaps 15 tons with 6 of coal. This points to the tremendous saving of over one-third of the fuel cost. Furthermore, as the custom nowadays is to utilize the waste heat by interposing the steam boilers in the flues, whereby about half of the heat value of the original fuel is conserved, it is easy to see that the new style reverberatory is a most economical apparatus, beyond comparison with its predecessors. So far as I am aware, the high-water mark of capacity has been reached at Steptoe, Nevada, a single oil-fired reverberatory there having put through, according to the manager's statement, no less than 660 tons of material in one day of 24 hours. A portion of this consisted of hot calcines, another of cold ore, another of molten converter slag, etc. Contrast this with the former habit of charging 10 to 15 tons per day. But, of course, the old furnaces were devoid of facilities for charging either hot ore or molten slag; so the comparison is not so severely against them.

The crude method of casting the slag in sand molds near the furnace has been supplanted by the use of the granulating stream, and by the almost equally economical means of large railway pots, by either of which it may be removed with dispatch to comparatively distant dumps at slight cost. If one considers the means now employed, it will be confessed that the reverberatory practice of today has reached apparent perfection almost in every conceivable direc-

tion. There is certainly but small opportunity for new progress in this department of metallurgy unless the waste heat held by the slags at the the moment of skimming be excepted. These carry off, as has been amply demonstrated, an amount of heat which, were it to be saved, would suffice, for example, to heat the incoming air for the firebox to several hundred degrees, and thus serve an important purpose, saving a considerable proportion of the fuel. The method is patented; and the royalties demanded, though very small, have kept it from use thus far, although it is highly probable that on the expiration of the patents it will be adopted by several concerns that have made elaborate inquiries as to its adaptability to their conditions. Notwithstanding the preëminent success of the long reverberatory in the United States, the fashion has not yet spread to foreign shores, and we hear of the construction in various regions outside of our own country of short-hearthed furnaces of the reverberatory form. This conservatism is well illustrated by the building of the two furnaces at the now well known Messina copper mine, in the Transvaal, South Africa.*

Reverberatories at Messina

The directors of the Messina property seem to have approached the metallurgical subject with extraordinary timidity, considering the apparently favorable conditions surrounding their undertaking. Some British companies seem to enjoy working out the details from the beginning of a process, as if they were the first in the field, preferring to ignore the results and practice achieved by previous workers. Contrary to the general impression among metallurgists that the initial steps in the introduction of a smelting or other process are painful, some of our friends across the water appear to revel in the trying and fitting stage, possibly under the impression that the ground was never trodden before. American metallurgists, and no doubt many foreign ones also, will smile at the installation of "a pair of 23-ft. reverberatories," and more broadly at the production of a 50% matte in one operation, leaving 1.5% copper in the slags. But what will they say to shipping a 40% concentrate out from the heart of Africa, along with the aforesaid matte? And by what sort of legerdemain do the Messina metallurgists achieve "10 to 15% jig middlings"?

An immense amount of detail has been gathered about the apparently simple methods and apparatus of reverberatory smelting, and this brief article might be expanded to a portly volume without entirely exhausting the subject. The chemistry of the reactions; the scope of usefulness, the comparative advantages of the blast-furnace and reverberatory; the consideration of draft; the utilization of the waste heat, and the style of boilers best adapted thereto; and many other matters of importance in this inquiry might receive useful consideration.

SOPA DIAMOND MINES.

Diamond Mining in Brazil

Diamond-mining in Brazil is an ancient industry. The methods employed are said to be the same in many particulars as in 1700 when the work began. We present herewith a number of pictures illustrating the simplicity of equipment and methods that are still in vogue, furnished through the courtesy of William O. Taylor, of the Diamond King Mining Co., at Diamantina, Minas Geraes. The native method of work consists of open-pit digging, and concentration by hand in the *batea*, the sharp-pointed pan of Brazil, which is often, at least, made of wood. Where necessary and possible, the overburden is washed off by diverting water from the stream in ditches. The gravel is first concentrated in *bacu*, losing thereby the fine gold and possibly some of the diamonds, and then re-concentrated in large wooden *bateas*.

Not all the work is so primitive. The Sopa Diamond Mines, Ltd., as will be seen from the picture above, employs a more expensive plant and brings the diamond-bearing earth to it by means of side-dumping cars hauled by a Best steam tractor. This Company operates about six miles west of Diamantina, Minas Geraes. It is an English concern organized in February 1911 to acquire and operate properties, water rights, and mineral lands comprising a total of 3428 acres.

The Diamond King Mining Company has had a dredge in operation at Mendanha since 1907, dredging for gold and diamonds. The sand and gravel from the gold tables is passed to a revolving screen and then to jigs where the diamonds are recovered. The great part of the Brazilian diamond production is obtained by native labor who work as lessees on a royalty basis, the property owners purchasing the diamonds from the natives. As a producer of black diamonds, or 'carbons' as they are more commonly called, Brazil ranks first and an ever increasing demand makes the outlook of the industry most encouraging. While the gems are found to some extent in Brazil, the production is of a very secondary importance to that of the 'carbons'. During 1912 the total diamond import of the United States was valued at \$41,363,325.

Various attempts have been made to interest North Americans in the Brazilian diamond fields, and there are a number of companies that are controlled in the United States. For one reason or another, the business has not as yet achieved brilliant success, though the finding of a gem stone weighing 246.4 lb., as reported, would seem to warrant even large expectations.

Ore Transport in Rand Mines

*The transport of ore underground in Rand mines has received considerable attention, and at several of the mines there has been a notable improvement in this work, according to John Munro, the retiring president of the Chamber of Mines. The tendency now at many properties is to use heavier tracks and larger cars, and to pay more attention to the upkeep of this equipment than has been the case hitherto. A great deal of time, labor, and money has been wasted in the past. In the mines of one group, the total cost of shoveling and tramming has varied from 34 to 72c. per ton handled, according to conditions. In the last three years, although many improvements have been effected in regard to ore-handling methods, there has been no diminution of cost, and the obvious explanation is that the economy resulting from better practice has been absorbed by the burden of extraneous expenditure. There is, of course, plenty of scope for economy in regard to this department of mining on the Rand, as indeed there is scope for economy in every branch, and under more favorable conditions charges in connection with ore handling should be substantially reduced.

The driving of main-haulage levels, and concentration of underground transport operations is an important factor in securing better underground ore transport conditions. At a number of the larger mines of the Rand these main haulage-levels are being driven right across the properties concerned along the strike of the 'reef' from one boundary to another. As a few examples of mines possessed of these main haulage levels, may be mentioned a few subsidiaries of the Central Mining & Investment Corporation. The Crown Mines has, for instance, the No. 13 level driven across a considerable portion of that property and equipped with electric locomotives. Below this, No. 16 has also been laid out as a main haulage-level. The Village Deep, City Deep, and Modderfontein B, among other companies, have also well equipped main haulage drifts. Main haulage levels are, of course, not practicable or economical in all mines. Where the width of the property from east to west is small, or where the dip is very steep, main haulage drifts would have little to be said in their favor. The value of levels of this nature depends on the extent of operations and the quantity of ore that can be concentrated on them. The life of the mine which it is proposed to equip in this manner is obviously another material consideration.

It is interesting to note the various methods of ore transport underground as practised on the Main Reef series. Hand tramming need not be discussed, which naturally obtains along levels not specially widened and equipped as main haulages. One of the most modern underground ore transport equipments in the world

is that possessed by the Crown Mines company on the No. 13 level. This level will eventually be about three miles in length, and it is 14½ ft. wide and 9 ft. high. The permanent way is laid with 45-lb. flat-bottom rails. Twelve-ton cars, with a maximum of eight in a train, are used for the conveyance of the ore. The employment of these large capacity trucks has proved so far a success. Their adoption and the method of running have resulted in a large saving of time and labor in **loading and discharging, and in maintenance charges**, which would have been incurred had small side-tipping cars or fixed well-bottom cars been used. They are of novel design, being of the side-discharge saddle type, mounted on four-wheel bogies, with buffer draw-bar attached to the bogie frame, instead of to the main body frame as usual. The cars are drawn by 100-hp. electric mining locomotives at a speed of 10 miles per hour. These locomotives weigh eight tons each and have two motors, which may be run in series or in multiple, thus giving two speeds without resistance losses. They are capable of exerting a draw-bar pull of 3200 lb. The current for the locomotives is furnished by two motor-generator sets, each consisting of 250-kw., 500-volt, compound-wound generator, direct coupled to a 2000-volt motor. These sets are placed in the pump chamber at No. 13 level, and will ultimately furnish current for No. 16 and 19 main levels, in addition to that now used on the No. 13 level.

In the western part of this great property, petrol locomotion is employed. On the first level drift of the Langlaagte Deep, locomotives of 16 to 25 hp. are installed. These pull 30 tons per trip in 3-ton saddle-back cars. Other methods of mechanical transport in use are endless-rope and tail-rope haulages. Animal transport is employed on the City Deep, and at the Modderfontein B both animal and tail-rope haulages are in use. The foregoing will serve briefly to show how much heed is today being given on the Rand to a branch of mining work which in the past was largely neglected. One is certainly justified in looking for some reduction in working expenses in this direction in the near future.

The probable tonnage that will pass through the Panama canal has been estimated as follows by experts for the French government:

| | 1915. Tons. | 1925. Tons. |
|-------------------------|----------------|----------------|
| Westward movement | 919,000 | 1,160,000 |
| Eastward movement | 746,000 | 941,000 |
| Total | 1,665,000 | 2,101,000 |

M. Douvry estimates for 1915 a total of 1,858,903 tons.

The estimated population of the United States is 98,781,324, against 91,972,266 at April 15, 1910. With all of its possessions, the United States has a population of 109,000,000, according to the Bureau of the Census.

*Abstract from *The South African Mining Journal*.

Industrial Hygiene as Practised at Palmerton, Pennsylvania

By JOHN W. LUTHER

*The fact that this Institute of Mining Engineers has invited us to address you on hygiene this evening, I consider extremely significant, indicative of this time of social progress. Twenty-five years ago such a thing would have been an impossibility. Human life has, until quite recently, been held cheap, while material things have had a distinct value in all ages. A machine which has some intrinsic value has always been most thoughtfully selected and tenderly cared for; but what about the poor human machine? If old and disabled from accident or disease incident to his occupation or not, he could be discarded without pecuniary loss and a new human machine substituted. But this is no longer possible, profitable, or desirable.

The discovery of the cause of a great many diseases, through the remarkable advances in the study of bacteriology, has in a great many instances led to prevention and in some cases cure. This has led men of an inquiring mind to investigate practically all diseases resulting in the discovery of cause, and prevention in many of them. The known occupational diseases fell in the class that was investigated, and many of them were found to be preventable.

Government Control of Sanitation

Both federal and state governments looked into the unsanitary conditions in work-shops. The American Association for Labor Legislation sprang into existence, and now every state and the federal government have passed laws governing the sanitary conditions under which labor is to be performed. These investigations by the governments and individuals have done more, however. They have shown that almost every occupation has its peculiar pathology, or that certain diseases are more prone to occur there than in other occupations. The morbidity and mortality rate for tuberculosis is far higher in clerks than in farmers; in pottery men than in furnacemen; in brief in those whose work is light and confining than in those doing heavy work in the open. Certain occupations are classed as dangerous in consequence of attracting a class of workmen who may be peculiarly susceptible to disease. Hence the importance of examining every employee before he is employed to see that he is placed at work which he is physically fit to perform with the least possible detriment to his own well being. If this were carried out universally I believe the stigma of occupational disease would be removed from many occupations.

An outcome of legislation regulating the sanitary conditions of work shops has been the factory inspector. This is a good thing, for he helps those who

want to help their workmen, and forces into line those who do not. Another good result is the reporting of all cases of accidents and occupational disease and compilation of accurate statistics. But here a difficulty arises. Just what is an occupational disease?

Compensation and Liability Laws

The American Association for Labor Legislation is waging a most active and successful campaign to secure the enactment of a model bill by all states not already provided with similar legislation. Their bill, the Kern-McGillicuddy (H. R. 14994), they are endeavoring to have passed by Congress to apply to all civilian employees of the federal government. It differs from many bills in that it provides compensation for occupational diseases as well as for injuries. It reduces the waiting time to 3 days instead of 15. It provides 66⅔% of regular pay for disabled workers during the period of their disability. It provides reasonable benefits for widows, children, and a limited class of other dependents.

The first thought of the employer is, how can I protect myself? How better than by sanitation, safety devices, and physical examination of all employees to determine the physical soundness of all of them. The ultimate outcome will be that instead of being employed and doing what they can, many will be debarred from work and will fall upon the taxpayer for support.

Physical Examination

Physical examination is one of the employer's defenses against compensation legislation, for without it great advantage may be taken of the employer by a workman demanding compensation for a pathological condition which may have existed before his employment. Hernia is a notable example of this. Having been examined before employment, each man placed in a position to counteract an occupational disease should be inspected monthly. This inspection should be directed toward the determination of the existence or absence of the disease peculiar to the occupation. In addition, each employee should be subjected to a semi-annual examination which should be fairly thorough.

By this method the development of almost any occupational disease can be discovered in its incipency and the man transferred to another part of the plant to prevent its advance and in a great many instances, perhaps, effect a cure. In addition to the eradication or diminution of occupational diseases, a record is made by means of which can be seen at a glance whether or not the man is fitted to the work for which he is employed. If not, he can be transferred to other work. Adopting this policy, the New Jersey Zinc Co. keeps

*Abstract of an address delivered before the New York section, Amer. Inst. Min. Eng., April 22, 1914.

its men in the highest degree of physical fitness and accordingly increases their efficiency. I think this will be found to be true in the quantity and quality of output, the returns for which will more than pay the cost. In addition to this there will be less lost time, the men will be more contented at work, consequently labor troubles will diminish, and it is natural to suppose that the influence of cleanliness, general hygiene, and physical care at work will be felt at home.

In connection with this might be mentioned our method of handling the sick and injured. Any man hurt or taken ill on the plant is referred to our emergency hospital, where he is given first-aid treatment and then referred to the hospital. This man cannot return to work until given a written release by the surgeon, who states whether he can resume his usual work or should be given light employment. Any man who reports off on account of sickness is reported to our district nurse, who looks him up and reports on his condition. Before this man returns to work the physician in attendance must fill out a form giving the diagnosis of the case. This is sent with the man to the surgeon, who releases him and allows him to return to work. By this means we try to overcome malingering.

Value of Coöperation

There is one important point in all sanitary, safety, and welfare work which must not be forgotten. That is, that to carry out effectively any plans it is essential to secure the coöperation of the men. How can this be better assured than by educating them? This can be accomplished by health talks, illustrated lectures, distribution of health pamphlets, training of the first-aid squad, and by the use of Tolman's 'Hygiene for the Worker' (American Book Co., New York). Our first-aid squad makes regular tours of inspection of the plant, reporting not only unsafe places, but notes what they may consider to be unsanitary conditions.

Cleanliness is essential everywhere and is, to my mind, the keynote of sanitation. Infection of wounds is reduced to a minimum by first-aid treatment. Dust, fumes, gases, and vapors are cared for by adequate ventilation, and by hoods. In such places as the bag-room and the packing house of the oxide department, where the dust cannot be removed by any means, the men are required to wear respirators. The ordinary cover respirator is used, though one of our men is working on one which will far exceed this in efficiency, while a large part of the objectionable features will be done away with. Clean sponges are provided and given to the men whenever they want them and every respirator is sterilized by soaking in carbolic acid, 1 to 40, for an hour, and then thoroughly washed every week, or more frequently if necessary. I often hear the remarks, "We cannot get our men to wear respirators," and until I visited the Pullman plant I supposed this to be true. They demonstrated to me con-

clusively that it can be done; that men will wear them if the fact that they must, that failure to comply means immediate dismissal, is impressed upon them when they are employed. Success or failure here depends on the atmosphere created by the men above. Respirators at their best are dirty, warm, uncomfortable, and not wholly efficient, so any improvement will be welcome. The present respirators when not in use, before being transferred to another man, should be kept in an atmosphere of formaldehyde for at least 24 hours, then washed in weak ammonia solution and aired, and clean sponges and rubber straps supplied. This treatment will not only sterilize them, but will prevent the rapid deterioration of the rubber and will not harm the metal parts.

Zinc Poisoning

Is zinc poisonous? We maintain that it is not. For over six years I have been surgeon to the largest zinc plant in the world, and I have yet to see a case that even approximated a metallic poisoning. On questioning some of our old hands as to their knowledge of zinc poisoning, some of them will admit to having had acute attacks in the old days, but not recently. The symptoms described by them resemble carbon-monoxide poisoning rather than the so-called 'zinc-shakes' associated with the brass founder's trade.

Sir Thomas Oliver, the greatest living authority on occupational diseases, states that zinc is non-toxic and claims that "animals exposed to oxide of zinc in the form of dust or who received it in their food over a length of time" showed no signs of poisoning. This we have ourselves confirmed. In his visits to the large smelting works at Bleiberg, Belgium, he could not find any evidence of ill health among the workmen traceable to the zinc itself. Rambousek, professor of factory hygiene, and Chief State Health Officer, Prague, and many others state that "industrial poisoning from zinc is unknown. The chronic zinc poisoning among spelter workers described by Schloekow with nervous symptoms is undoubtedly to be attributed to lead."

Brass Founders Sickness

As regards the 'spelter-shakes' or 'brass founders sickness' already mentioned, the balance of the evidence appears to be in favor of copper being the main, if not the only cause of the trouble. As stated before, this particular sickness does not occur in spelter workers, and my own experience shows it to be non-existent at the Palmerton plant.

In our oxide department the men live in the atmosphere of zinc. They inhale it, eat, and absorb it through the skin. The only effect I have found is a drying of the nasal mucous membranes and a tendency to develop bronchitis, though pneumonia among them is very rare. For this reason the use of respirators is insisted on. It must be remembered that this product contains no lead.

There is a tendency among all workmen to attribute any indisposition to their employment. Workers in

the oxide bag-room and packing house show this disposition. I have gone carefully over the records for the past six years and find that gastro-intestinal discomfort occurs with almost equal frequency in all departments, including the shops, but only in the oxide department is it attributed to zinc. In the spelter department, where zinc poisoning would be more likely to occur, owing to the vaporization of the metal, zinc is never given the credit. Here it is attributed to carbon monoxide.

Carbon Monoxide Poisoning

Acute cases of carbon monoxide poisoning do occur occasionally on our plants in both the spelter and spiegle departments, and it does not seem possible to absolutely prevent it. Leaky pipes in the spelter department and the escape of gas during the cleaning of dust catchers in the spiegle department seem to be responsible. Since January 1913 we have had 55 cases of carbon monoxide poisoning, but only a few were sufficiently severe to actually require the pulmotor, and in most of these it was used for the administration of oxygen and not because of suspended respiration. Only once during my connection with the plant was it necessary to remove the man to the hospital to perform venesection before he regained consciousness, and he was an alcoholic. In the history of the plant only one death from gas is recorded and this was due to carelessness on the part of the attendants.

The gas being odorless and colorless, a man may be overcome before he has time to realize his danger. The greatest care must be exercised to avoid leaks, but at times they will occur, notwithstanding the greatest vigilance. Our first-aid squad is regularly drilled in the treatment of these cases. Recently we inaugurated a definite system of gradually drilling the employees in this work. Our active squad in actual training consists of eight men under the leadership of our safety inspector, who devotes his entire time to this work. Every two weeks two of the men leave this squad and two new men come on, so each man serves eight weeks. The men are as equally divided as possible among the various departments. We now have 60 men scattered throughout the works who have served their time and who are entitled to wear our safety button. In case of a carbon monoxide poisoning, one or more of these men are sure to be nearby and immediately starts artificial respiration until the pulmotor can be secured. This is used in all cases. The surgeon on the plant is always summoned, but only twice in the past year has he arrived on the scene before the First Aid squad succeeded in reviving the patient.

Drinking Fountains

After guarding the men against the risk of occupational disease, they must be protected against the danger of contracting disease from their fellow workmen. For this purpose sanitary drinking fountains are installed. Our industrial water supply is not pure, at

all outlets from these mains, therefore signs are posted prohibiting its use. The drinking water is of a good temperature, so the use of ice is forbidden and intestinal colic has been almost eliminated.

Of the greatest importance are the change houses and toilets. We have been working for some months on the plans of what we consider an ideal change house and have finally adopted it as a standard. In it we have made some radical changes. It is arranged so as to be readily connected by covered passage or directly with the shop for which it is intended, as is required by the Pennsylvania law for foundries. Just inside the door is a battery of toilets. The ordinary toilets are poor affairs at their best, and are difficult to keep clean, and many men will refuse to use them for fear of infection. To obviate these objections a toilet has been selected which cannot be used as a seat, doing away with the obvious objections. These toilets are separated one from the other by metal screens painted white.

Change Houses

Just beyond the toilet and separated from it by double swing doors is the change house proper. Here are benches arranged in parallel rows and elevated the usual distance from the floor on enameled pipe legs with aisles sufficiently wide to enable men on opposite sides to change their clothing without entirely obstructing the aisle. The actual distance from the centre of one bench to the centre of another is 10 ft. and each man is allowed 2 ft. on a bench, giving him 10 sq. ft. for his own use. Instead of the usual locker we have substituted a woven wire basket fastened to an endless wire cable which runs between the back of the bench and the ceiling. The basket provides accommodations for a lunch can, and on the under surface are attached 4 hooks, one from each corner, on which the clothing is hung. This being elevated from the ceiling, the warmest part of the room, the clothing dries quickly and all odors arising from them are carried out through the monitor on the roof. They are elevated sufficiently to prevent the possibility of anyone passing underneath touching them. They are so arranged that each man can lock his basket in position. In lowering it, it drops in front of his bench at proper height for him to comfortably reach his clothing and yet sufficiently far away from the bench to enable him to clothe himself readily. The opposite end of the room is provided with ample shower baths, sufficient to take care of the number of men provided for in the change house. This plan provides for 60 men and one shower is provided for every ten men. At the other side at the end of this room are the wash troughs. The individual basin has been done away with and the space given up to an enameled trough with tempered water running continuously from a pipe above. Water is tempered from one end so that there is no possibility of the men scalding themselves. In addition to the tempered water, a cold water pipe is also provided. The wash trough is

so placed that a man standing at one spot can see that every man has washed his hands and face thoroughly before passing through a double swing door, a covered passageway, another double swing door into the lunch room. This is of importance where leaded ores are worked, but in Palmerton, where at present no lead is contained in the ores handled, it is of but little importance. In the lunch room ample table and bench space is provided for each man. Should it be necessary to conserve ground space, the covered passage way can readily be connected with a checking station at the gate of the plant, so that if necessary it again can be seen that the men thoroughly wash themselves before going home; this is not only important, but required in certain states where leaded ore is handled. The floor is made of concrete, the shower bath and wash trough space is covered with wooden slats so that the men do not have to walk on the cold floor in bathing.

The walls are of hollow tile cemented on both sides. The advantage of having the lunch room entirely separate from the change room is obvious. Odors from the wash room are bound to arise, and by this method they are kept out of the lunch room. Where leaded ores are handled and it is necessary to supply working clothing and towels, a supply closet for these materials can readily be built in at one end.

The results of our efforts in the conservation of human life and limb are perhaps best shown by the fact that, among an average of 2000 employees since January 1908, we have had but 9 deaths that could in any way be attributed to occupation; 2 from heart disease that might have been avoided had the men been examined before employment, 4 in consequence of violating rules and disregarding safety devices, 1 from thermic fever, 1 from delirium tremens precipitated by a burn, and 1 from the result of a faulty machine.

Ore Occurrence at the Cloverdale Mine

By LEROY A. PALMER

The Cloverdale mine, in Sonoma county, California, presents an occurrence of quicksilver ore that is of interest in that it is not found in veins, but as disseminations through a quartzite matrix. The mine is situated about 12 miles east of the town of Cloverdale and has been operated for the past 40 years.

THE CLOVERDALE MINE.

the total production of quicksilver therefrom being valued at about \$400,000. Refining is conducted in a furnace on the ground. Several adits have been driven into the steep hillside, a shaft sunk, and a haulage system, including two balanced gravity planes, has been installed. The ore treated averages about 10 lb. of mercury per ton.

The cinnabar, which is the form in which the mercury occurs, is found in the quartzite which forms the upper portion of a hill which rises steeply on the north side of Sulphur creek. The general age of the formation is about Jurassic, and the hill consists of a coarse-grained friable sandstone and the quartzite, the latter overlying the sandstone with apparent un-

conformity. The difference in the hardness of the two rocks produces such an effect on the erosion of the hill that the approximate contact can readily be traced from the topography. The quartzite is many colored and often shows extensive mineralization.

The strata making up this hill have been subjected to strong lateral pressure, resulting in a series of very abrupt folds, the axes of which have general northerly and southerly strikes, in which the rocks have been crumpled almost within their own thickness. Where the quartzite has been thus folded the layers have been forced apart and the interstices filled with gray and light-green talc. It is probable that these convolutions are fracture folds, as it is in their vicinity that the cinnabar is found as blotches and disseminated grains in the quartzite; that is, not between layers that have been separated by folding, but in tiny crevices in the quartzite itself. The general appearance of the ore, so far as this feature goes, is very similar to the disseminated copper ores of Bingham and Ely. The folds mentioned are naturally accompanied by many faults, but none of these is prominent. Instances of slickensiding are pronounced.

The source of mineralization is presumably a strong fissure of general easterly strike which has been observed west of the quicksilver deposits and striking toward them, but which has not been opened on the quicksilver ground. It is a notable fact that there are no intrusives which appear to have any connection with the mineralization of the district, the only intrusive near being a dike, presumably monzonite, which is found with northerly strike some distance west of the cinnabar deposits. On top of the hill is a capping of sandstone in which a small amount of the ore has been found as a contact deposit, but it is evident that the real supply is in the quartzite. There is evidence that this will be productive for some time to come, as the mineral seems to be abundant in the vicinity of the folds and there are many of these which are still unexplored.

Graphic Solutions of Certain Compound Interest Problems

By HORACE F. LUNT

The problem of arriving at the value of a mine often takes the following form: The mine may be expected to produce a certain net income for a certain number of years; what is its present value at a given rate of interest? This may be solved by one of the two following formulae for the present value of an annuity of one for n years:

$$(1) \frac{1 - (1 + i)^{-n}}{i} \quad (2) (1 + i)^{-n} \frac{1 - (1 + i)^{-n}}{i}$$

The first is to be used when the annuity is to begin at once, and the second when its beginning is deferred for d years.*

So far as I have been able to ascertain, the published

means of which most of the calculations involved in the solution of these problems may be avoided. Their use may be explained by the following example.

Assume that an examination has shown a mine to contain 1,000,000 tons of ore having a net value of \$3 per ton which can be extracted at the rate of 100,000 tons per year, and that the interest desired is $12\frac{1}{2}\%$. From the chart, Fig. 1, it is found that the present value of an annuity of \$1 at $12\frac{1}{2}\%$ is \$5.50. Multiplying this by 300,000, the annuity the mine will pay, there results \$1,650,000. If the mine is a going concern and profits can be obtained from the start, this represents its present value. If it will be, say, three years before profits begin, the second

FIG. 1.

FIG. 2.

tables of compound interest are only for the low rates used by trust companies, savings banks, and so on. As mining investments have to promise returns of 10% or more to be attractive, these tables are seldom of use to the mining engineer. To solve a single problem by one of the above formulae is not much trouble, but when negotiations are in progress and several results are desired in a hurry, the calculations become laborious. To facilitate my own work I have constructed two charts for various rates of interest by

*All problems in compound interest, including sinking funds and present values, depend for their solution on one or more of the six formulae, given below for convenient reference. In these formulae n is equal to the number of years (or periods) and i to the amount of the interest for one year (or period). Care must be taken to give i its correct numerical value: for instance, the value in the first example given, where the rate is $12\frac{1}{2}\%$ and the period one year, i is equal to 0.125.

formula must be used. From the chart, Fig. 2, the value of $(1 + i)^{-n}$ is found to be 0.70, and multiplying this by \$1,650,000 I get \$1,115,000 as the present value of the mine. In the latter case it would very likely be necessary to subtract, from the value found by the method given, the cost of improvements that would be necessary before profits began.

This method gives results that are somewhat low, as it is assumed that the interest is compounded annually, whereas in practice dividends are usually paid more often than once a year. Generally, however, this is as accurate as the data on which it is based. If it is desired to be more accurate, exact results can be obtained by taking as i the amount paid at any period and as n the number of periods. In the assumed case, suppose dividends are to be paid quar-

terly; then i will be equal to 0.03125 and n will be equal to 40, and by formula (1) the present value of the mine will be \$1,702,500.

- (1) The sum which l will amount to in n years is $(l+i)^n$
- (2) The present value of l due in n years is $(l+i)^{-n}$
- (3) The amount of an annuity of l in n years is $\frac{(l+i)^n - l}{i}$
- (4) The present value of an annuity of l for n years is $\frac{l - (l+i)^{-n}}{i}$
- (5) The annuity which l will purchase for n years is $\frac{l - (l+i)^{-n}}{i}$
- (6) The annuity which will amount to l in n years is $\frac{l}{(l+i)^n - l}$

Assaying Concentrate and Black Sand for Gold and Platinum

By ANDREW F. CROSSE

*Little has been published on the methods used for estimating the amount of platinum contained in ores and concentrate, etc., but a great deal of work has been conducted on the separation of alluvial platinum, the results of which have been published. Considerably more testing must be done before the best methods can be determined, but this must be paid for by those who would derive benefit from it. The following table shows three methods of assaying black sand, etc., for platinum. Parts of the process are original, and the combination is new.

Elevating Pulp

In deciding upon a suitable scheme for lifting ore pulp in mills, it is necessary that due regard should be paid to two important factors. One of these is the question of the fineness to which the ore has been ground, and the other refers to the height required to elevate. The necessary velocity of vertical flow is in a direct ratio to the coarseness of the ore in the pulp. The specific gravity of the ore also influences the operations in the same way. Hence, where coarse crushing is practised, it is obvious that the cost of elevation of the unground ore must be high, whatever pumping system is adopted. A high velocity is needed to prevent the settlement of gravel in the suction and delivery pipes, and heavy wear and tear is unavoidable. Practically the only type of pump suitable for such work is the centrifugal. In these pumps the economical lift with an ore pulp is limited to about 30 ft. An additional disadvantage resulting from their use lies in the fact that ample gland clearance water at pressure is necessary. This means additional power consumption, and generally an unwelcome dilution of the pulp. As an alternative to the centrifugal pump, the tailing wheel is quite suitable for the elevation of a mill pulp carrying coarsely crushed ore. Although somewhat clumsy in appearance, their cost of upkeep is less than in the case where centrifugal pumps are used. With an ore which is comparatively finely crushed in the batteries, or in tubes after a direct flow from batteries to them, the problem of pulp elevation is simple. Frenier pumps are suitable for lifts up to about 20 ft. or so

The value of the lead and zinc produced at mines in Kansas in 1913 was \$1,343,432, compared with \$1,680,744 in 1912, according to J. P. Dunlop, of the U. S. Geological Survey. In Arkansas the value was \$55,120 in 1913, compared with \$106,014 in 1912.

*Abstract from *Journal of the Chem. Met. & Min. Soc. of S. Africa.*

and an air-lift has an additional advantage over this type of pump in that, besides requiring no gland clearance water, the cost of upkeep is practically nil. For elevations above 20 ft. or so, the three-throw pump of the plunger type is a satisfactory machine if designed properly. Wear and tear is small, the velocity of the pulp is low, and sudden break-downs are few.

Mine Oil-Houses

By P. B. McDONALD

The chief objection to a wooden oil-house is the tendency of wood to soak up oil. Besides being dangerous on account of fire, such a construction is undesirable for many reasons. However, if the oil-house is carefully tended by one man, he can keep a wooden building in good condition by using trays or pans to

found to be a good plan to keep all the oils under the steel floor and pump the oil up into the cans to be filled; then if any is spilled it will drain back. The oil coming to the mine in wooden barrels is placed on the floor of the oil-house and emptied into the steel barrels below. Barrels of grease have to be kept on top with the heads knocked in, but grease never gives much trouble.

The accompanying sketches show the construction of a steel-frame oil-house. The foundation of this oil-

catch drippings. Usually several men have access to a mine oil-house, and sudden demands for oil for some obdurate rock-drill or tram-car result in oil being spilled. In cold weather when the oil runs slowly, such measures as knocking in the head of the barrel and shoveling the oil into pails have been known. In all cold climates the oil-house should be heated; exhaust steam is a cheap method. Oil-houses fitted with broad shelves are well liked when the oil barrels lie on their side and so inclined as to bring the drainings of the barrel to the front. It pays to buy good faucets for the barrels; the cheaper ones leak and require a pail set under them. A regular molasses spigot is satisfactory for cylinder and engine oil. It is difficult to keep kerosene from leaking with any spigot, and is better handled by a pump. One company in the Lake Superior district, after a thorough investigation, recently drew plans for a standard fire-proof oil-house to be used at all its mines. It was

house is made of concrete, and on the concrete foundation lie seven I-beams 3 ft. apart. The floor is of sheet steel. The columns are made of angle irons, as are the five trusses, which are 5 ft. 3 in. centre to centre. There are four windows. The building in this case was covered with a material bearing the trade name 'Hy-rib.' This material is a combination of light steel wickerwork over which is plastered concrete. There are usually two layers, leaving an air space between. Besides being used for walls, it is sometimes used for floors and roofs. Other materials, such as galvanized sheet iron and special sheetings, are also used. Some special roofings have chicken-coop wire mesh as a framework. The cost of each truss as shown in the sketch, figuring steel at 2c. per pound, is about \$2, making the five trusses cost only \$10 in material. Old, second-hand, light rails can be used to reinforce a concrete roof. This type of oil-house is both fireproof and convenient.

Geological Investigations at the Ivanhoe Mine, at Kalgoorlie

The following notes are from the last annual (1913) report of the general manager of the Ivanhoe company. During the year, J. Malcolm Maclaren was requested to examine and report on the question of the East lode and the influence of the porphyry dike at depth, as disclosed by developments subsequent to his previous examination. This report was submitted in August, and by way of a brief summary of same it may be stated that Mr. Maclaren predicted that the East lode would pass through the porphyry at a vertical depth of 3380 ft., taking the point at Section 8, but while the porphyry zone would be unreliable, it would not necessarily be barren, and profitable ore would probably be opened in places within the same. In order to further test the location of the porphyry dike, a diamond-drill bore-hole was put down from the station at the 2870-ft. level, going east and inclined at an angle of 39°. This bore-hole entered the porphyry at a vertical depth of 3028 ft., and 215 ft. east of the shaft, passing out of same at a vertical depth of 3200 ft. and 6 ft. west of the eastern boundary, thus showing the dike to be 271 ft. wide at the point passed through by the bore. In the bore-hole a vein of mineralized rock was cut in the porphyry at a vertical depth of 3067 ft. and 263 ft. east of the main shaft, showing a width of 8 ft. 9 in., but assays proved 2 ft. having a value of \$2.04 per ton, and the balance traces. This is assumed to be the East lode thrown west, and if this assumption be correct, its position and the location of the eastern boundary of the porphyry would mean an increased depth of approximately 120 ft. before the East lode would pass out of the porphyry, in Section 8, and assume its normal conditions as proved above the influence of the dike.

It is proposed to bore at a similar angle from the station at the 3170-ft. level, when the main shaft reaches that depth, and further prove the dip of the intrusive bar. In order to sink the shaft as rapidly as possible, four men are engaged per shift working two machine-drills, and good progress is being made.

The tonnage of ore estimated to be in reserve at the close of 1913 shows a decrease of 99,433 tons compared with the results for the previous year, and a reduction in value of 25c. per ton. This, in the main, is due to the fact that all the important development work for the year has been on the East lode in the porphyry zone at the lower levels, and although profitable ore was opened in places, it has been considered too unreliable to include in estimations, and a large quantity was unsuitable to treat in reduction works. This necessitated rather heavy withdrawals from the reserves in the upper levels, which have proved most satisfactory and continue to develop to highest expectations. The details of ore reserves down to 2420 ft. are as follows: East lode, 738,365 tons worth \$8.72;

Middle lode, 175,536 tons worth \$10.24; New lode, 53,600 tons worth \$10.68; and Boulder lode, 23,916 tons worth \$14.82 per ton; a total of 991,417 tons, averaging \$9.24 per ton.

World's Production of Lead

By C. E. SIEBENTHAL

The following table shows the world's production of lead apportioned according to source of ore. The figures are those of the Metallgesellschaft, reduced to tons of 2000 lb., except for the United States, for which the figures of the United States Geological Survey are used.

| Country. | 1911. | 1912. |
|---|-----------|-----------|
| Australia | 109,789 | 118,387 |
| Austria-Hungary | 21,605 | 23,589 |
| Belgium | 48,832 | 62,941 |
| Canada | 11,795 | 17,968 |
| France | 26,014 | 36,376 |
| Germany | 177,801 | 181,880 |
| Great Britain | 28,660 | 31,967 |
| Greece | 15,763 | 15,983 |
| Italy | 18,408 | 22,597 |

Nome Geology

The United States Geological Survey has just published a bulletin (No. 533), describing the geology of the Nome and Grand Central region of Seward Peninsula, Alaska, by Fred H. Moffit. The investigation of the mineral resources of Seward Peninsula by the Survey was begun in 1899, and geologic and topographic surveys have been made at various times since. The present report brings together all the information at hand regarding the occurrence of the auriferous gravels of the area. Much of this information is stated to be of scientific interest only, as many of the rich placers have been worked out. However, a knowledge of their mode of occurrence will be valuable, not only in this but in other regions, in helping to establish the natural laws which determine the distribution of gold in alluvium. As a record of one of the richest placer camps of Alaska, the report will have permanent value; moreover, as has been stated, there still remain many large bodies of gold gravels as yet unworked.

A diamond weighing 229 carats, was recently found by F. J. Van Zyle in the Pniel diggings of the Transvaal. It was slightly yellow, and was sold for \$11,000.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Foaming During Slime Agitation

The Editor:

Sir—In the article, 'Air Agitation by Continuous Method,' published in the *Mining and Scientific Press* of April 4, 1914, Donald F. Irvin mentions the large amount of foam that sometimes collects on the top of the pulp in the agitators at El Tigre. A case of similar foaming that I experienced may prove of interest to cyanide workers. The agitators used were 10 ft. diameter and 20 ft. high; and, like those at El Tigre, the height of the central pipe was only 66% of that of the tank. Continuous agitation was not practised, but the agitators were filled and emptied intermittently. The pulp was kept somewhat low to prevent the foam from going over the top. Mr. Irvin states that the foaming at El Tigre is aggravated by excessive alkalinity, but I found that it was apt to foam with low alkalinity, especially if the alkalinity was low at the beginning of agitation. The addition of lime, as soon as the agitator was charged, would prevent foaming, and, if no lime had been added, and foam was becoming troublesome, the latter would subside after lime had been added. If the alkalinity got too low during the period of agitation, there was always a decrease. I added more lime, but the alkalinity was never high, the idea being to keep it between 0.5 and 1 lb. per ton. The lime was slaked, thoroughly stirred with water and solution, and the resulting milk of lime poured into the charge, the amount added each time being sufficient to raise the alkalinity only a fraction of a pound per ton. Of course, if sufficient quantities of lime were added early in the period of agitation, there was little need for its addition in the latter part.

I cannot give a reason for the foaming; but in the case of which I write, the presence in the pulp of a soluble aluminum salt, presumably the sulphate, undoubtedly had a great influence on the foaming, and I believe it to be the sole cause. While all slime will make foam, yet the presence of some other substance seems to be necessary for the formation of a large quantity. Qualitative analyses, and the quantity of flocculent precipitate that formed in the zinc-boxes showed the presence of a large amount of aluminum oxide in the solutions. The ore occurred in a large dike of a light-colored volcanic rock, and that which was milled came from near the surface, so it was oxidized material. It contained considerable clayey matter. The sulphuric acid formed by the oxidation of the sulphide had acted on the decomposing feldspars

of the dike, and formed aluminum sulphate, which, being readily soluble in water, was quickly dissolved by the cyanide solution. Mr. Irvin states that "ore containing the largest proportion of slime, causes the formation of more foam than quartzose ores." As the water percolating through the ore and wall rock while they were in place, would carry but little, if any, of the aluminum sulphate, and other soluble salts out of the clay seams, while carrying them away more easily from the harder and more granular portions; as the soft formations are more thoroughly decomposed than the harder ones; also as the most silicious rocks are the last decomposed, the amount of soluble salts present in the pulp would vary with the amount of slime present. The slime at El Tigre may carry some soluble salt that causes foaming, though of course I cannot say that it is aluminum sulphate, as was the case in the instance I give. The aluminum sulphate or other salt, or perhaps a compound that is formed with the cyanide, probably acts as does soap in water. The blowing of bubbles in childhood has made us all familiar with the effect of blowing air into this common solution. The addition of slaked lime caused the precipitation of aluminum hydroxide and calcium sulphate according to the reaction:

and so removed the cause of foaming. Caustic soda has been used to precipitate aluminum compounds from cyanide solutions, but its use is undesirable because the sodium sulphate remains in solution, causing fouling; and also because an excess of the sodium hydroxide will cause the aluminum hydroxide to dissolve as sodium aluminate. Calcium sulphate, being but slightly soluble in water, will not remain to foul the solution, and calcium aluminate, being insoluble, would be precipitated if formed.

F. J. GIRARD.

Dedrick, California, April 22.

Specific Gravity of Specimen Gold

The Editor:

Sir—Under the heading of 'Concentrates' in your issues of November 1 and 8 last, I notice that there is a considerable discrepancy between the two formulae given for estimating the amount of gold in a specimen when its specific gravity and that of the gold and quartz are known.

In your issue of November 1, the percentage of gold is given as $\frac{100g_2(g_1 - g_3)}{g_1(g_2 - g_3)}$, whereas in your issue of November 8 the percentage of gold is given as $\frac{100(g_2 - g_3)}{g_2 - g_1}$. As it is manifest that both cannot be right, in order to obviate misleading statements, I have deemed it well to draw your attention to the discrepancy. I think you will find that the first-mentioned formula is the correct one, as I have often used a modification of this formula in estimating the percentage of cassiterite ($g_2 = 7$) in a gangue ($g = 2.65$).

whereby the percentage of cassiterite P is given by the simple formula $P = 160 - \frac{426}{g_1}$, or, conversely, the specific gravity of the ore is given by $g_1 = \frac{426}{160 - P}$

J. JERVIS GARRARD.

Johannesburg, February 2.

[We are glad Mr. Garrard has called attention to the error in the formula printed in our issue of November 8. The correspondent who transmitted it evidently made use of wrong assumptions in forming his original equation. The correct assumption is that the value of the specimen is equal to the volume of its two constituents, or $\frac{100}{g_1} = \frac{x}{g_2} + \frac{100 - x}{g_3}$.

The computations by means of which this is reduced to the form $x = 100 \frac{g_2 (g_1 - g_3)}{g_1 (g_2 - g_3)}$ may be found in our issue of February 24, 1912.—EDITOR]

The Rand Banket

The Editor:

Sir—I have read with the greatest interest the important series of articles contributed by C. B. Horwood on the subject of the gold-bearing conglomerates of the Witwatersrand region. Many phases of the subject are exhaustively treated and much has certainly been added to our knowledge of these deposits. I feel great hesitation in entering this discussion even in a superficial way, for I have never visited the field, and confess frankly to having no strong attachment to any of the various theories advanced. In occurrence and mineralization the deposits are unlike any to which an origin by hydrothermal solutions can unhesitatingly be ascribed, and at least equally great difficulties apply to the placer theory, even if modified by the explanation of recrystallization.

Mr. Horwood has given much merited attention to the pyrite 'pebbles', and his demonstration of their origin by replacement is an admirable piece of work. I have no doubt that this replacement has proceeded by approximately equal volumes, and his explanation of the narrow rings of silica, often surrounding these pebbles, by contraction of the hot pyrite is probably correct. Similar narrow bands of calcite or quartz often surround metasomatically developed crystals of pyrite. That the diabase dikes influence the metallization is a most interesting feature, though the influence is not universal. The constant connection of the occurrence of gold with that of carbon and in part also with that of pyrite are certainly important and significant facts. On the other hand, I fail to see any argument for the infiltration theory in the occurrence of traces of platinum metals, for such would inevitably be present in a conglomerate accumulated on the shores of ancient lands of schist and granite. Most important are also the statements and diagrams referring to the distribution of the gold in the various conglomerates; these sections are perhaps the most convincing arguments brought forward to support the infiltration theory.

On the other hand, it is certain that any conglomerate accumulated as noted above must contain detrital gold from the veins in the granite and the Swaziland schists. It is equally certain that the conglomerates were penetrated by hot waters containing hydrogen sulphide, which were competent to recrystallize the gold and convert detrital magnetite into pyrite.

This being admitted, what is the objection to assuming that the gold was precipitated with the pyrite and that it was contained in the 'magmatic' waters from the magmas of the Ventersdorp series of effusives? In spite of all that has been said, one objection consists in the absence of fissures; for, granted that the conglomerates are little more easily permeable than the sandstones, the whole series must at the time of deposition have been very porous and hot 'magmatic' waters would necessarily permeate the whole. In view of this, the concentration of gold in the conglomerates is still a problem. The volume of gold-bearing solutions must have been enormous.

In gold-bearing veins we often find fissures entering from porphyries into tuffs or sandstones. In such cases the usual rule is that the vein immediately breaks up and becomes poor.

Furthermore, the mineralization is unlike any other form of gold deposit. There are no 'mineralizers' like boron, phosphorus, or fluorine. Sulphur, of course, is present, but this is not unusual in a sedimentary series. There are practically no other sulphides, nor are the metals present which we usually find associated with gold.

The gold-bearing veins of California and Australia were deposited by solutions rich in carbonates as well as silica, and the carbonates are extremely abundant in the altered wall rocks. If the solutions of the Rand had been similar, much replacement of pebbles by carbonates would have taken place.

The solutions were not strongly alkaline, for much chlorite is present. They deposited no ordinary gangue minerals but quartz, and apparently not much of that. They deposited chloritoid—a mineral of regional metamorphism and unknown in hydrothermal deposits. Some of this so-called 'chloritoid' appears to me to be cyanite, and this aluminum silicate is equally unknown in hydrothermal deposits except in one instance of a high temperature vein.* If these solutions were connected with the intrusion of the diabase dikes, they were assuredly different from most of those which have formed gold deposits in other parts of the world.

WALDEMAR LINDGREN.

Boston, Massachusetts, April 16.

The Messina mine, Transvaal, reports as follows for February: ore treated, 5405 tons; concentrate, (39.7% copper) 1069 tons; smelter treatment, 316 tons middling yielding 66.75 tons of 59.4% matte; total output of concentrate and matte, 1136 tons averaging 40.8% copper.

*Taber, Stephen, Virginia Geol. Surv., Bull. VII, 1913, p. 214.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Copper, lead, nickel, silver, gold, and some of the less common metals are now commercially refined by electrolysis.

Flint pebbles, weighing about 20,000 tons, were exported from the coast near Havre, France, to the United States in 1914.

White lead is a definite compound with the formula $(\text{PbCO}_3)_2\text{PbO}_2\text{H}_2$, and the commercial white leads do not vary much from this composition.

Thermit recently mended a broken crank shaft, weighing 3 tons, of a suction gas engine at the Queen of the Hills mine, Western Australia.

Coke used in smelting 766,414 tons of ore, fluxes, and furnace products of the Tennessee Copper Co., in 1913, amounted to 42,152 tons, or 5.5 per cent.

Grinding-pans at the Ivanhoe 100-stamp mill, Kalgoorlie, now number one for each battery of five stamps. They are used as intermediate grinders.

Cut herringbone-type gear was fitted to the Belmont shaft hoist, Tonopah, in place of straight-tooth main gear, in 1913, greatly improving its operation.

Wireless telegraph stations, on coasts and ships throughout the world, numbered 3998 at the end of 1913, according to the International Bureau at Berne, Switzerland.

Power absorbed by the modern electric furnace is enormous. A furnace about 16 ft. square will consume 12,000 hp., sufficient energy for the requirements of a small city.

A geological examination of the rocks of the lower levels of the Perseverance mine, Kalgoorlie, shows that no danger is to be apprehended of the calc-schist having any deleterious effect upon the orebodies until much greater depths are reached.

Cost of producing copper at the Wallaroo and Moonta mines, South Australia, in 1913, was £56 15s. 10d., against an average realization of £69 15s. 9d. per ton. In United States currency these figures are equivalent to 12.18c. and 14.06c. per lb. respectively.

The approximate cost of preventing yellow fever is as follows, according to Colonel W. G. Gorgas: A village of 600 houses, \$1900 per month; and a city of 30,000 people and 6000 houses, \$5000 per month. This is on the basis of paying native labor \$1 per day, and solutions costing \$18 per gallon.

Water amounting to 21,000,000 gal. must be pumped for every foot sunk in the Tasmania gold mine, Tasmania. The present pumps have a combined capacity of 6,500,000 gal. per day, so only 100 ft. could be sunk per year with the present equipment.

Costs at the Tennessee Copper Co.'s mine and smelter in 1913 were as follows: development, 11.82c.; mining, \$1.02; freight, 7.37c.; smelting, \$1.39; converting, 14.32c.; and general, 19.26c.; a total of \$2.93. There was 470,135 tons of Tennessee and 35,516 tons of custom ore smelted.

Rubber production of the world in 1913 was 108,500 tons, against 96,000 tons in 1912. The Malay Peninsula contributed 47,000 tons of plantation rubber. Shipments of crude rubber from the Amazon valley in February 1914 was 4,074,442 lb. to the United States, and 7,406,037 lb. to Europe.

Imitation gold leaf, known as *blatt-metall*, is being manufactured in Germany. It consists of 75 to 85% copper, and 15 to 25% zinc, and sells for 17c. per book of 10 bundles. There were 73.4 metric tons of gold and silver leaf, value \$313,446, exported from Germany in 1913, of which the United States took 13.8, Great Britain 9.9, Russia 7.5, and France 4.6 tons.

Amicable relations between mining companies whose properties adjoin often leads to economies. The Ivanhoe and Horse-Shoe companies, at Kalgoorlie, have constructed an auxiliary electric circuit, so that in the event of a stoppage of the power-plant on either mine, current can be supplied during such stoppage from the mine not affected. The former's plant includes vertical high-speed English engines, and the latter German turbines direct connected to generators.

Snow disappears at high altitudes without melting, a fact apparently not generally understood. The matter is not a mysterious one for the snow actually does disappear as water vapor into the atmosphere, without melting. A reference to the equilibrium curve between solid, liquid, and gaseous water, which appears in nearly every recent textbook on physical chemistry will show that the change from the solid to the gaseous state is the normal one at low pressures and temperatures.

The amount of silver to be added to the gold in an assay to insure efficient parting with nitric acid, should vary with the grade of the ore and the size of the gold bead resulting. With a 2-assay ton charge on gold ores, assaying \$1 per ton and under, the amount of silver to be added may result in a ratio as high as 20 to 1. This amount may be proportionately decreased as the value of the ore increases from \$1 to \$10 per ton, the latter value with a 2-assay ton charge requiring a ratio of about 5 to 1. The parting in gold bullion assays is usually done with a ratio of 2.5 to 2.25 parts of silver to 1 of fine gold.

Special Correspondence

JOHANNESBURG, TRANSVAAL

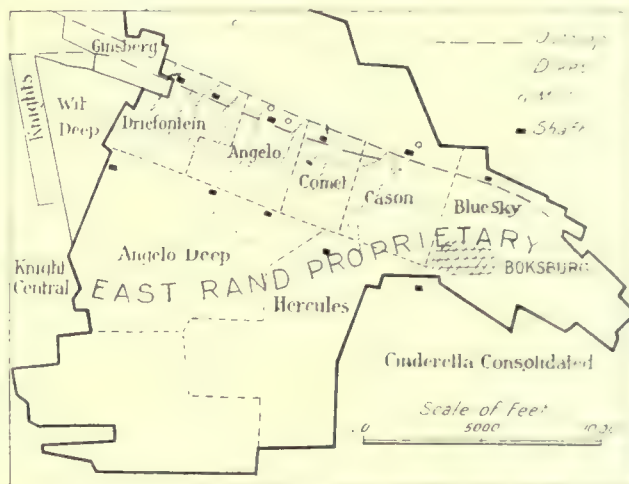

RESULTS OF THE EAST RAND PROPRIETARY MINES CO. IN 1913:
ORE RESERVES, PROPOSED DEVELOPMENT, AND PROBABILITIES
IN CERTAIN AREAS.

The appearance of the annual report of the East Rand Proprietary Mines Co. has lately been regarded as an event of some importance in the mining world, more especially on the Rand, as since the fiasco of 1911 the progress of this mammoth Eastern Rand undertaking has been watched with interest. The net profits earned during the year amounted to £831,565, of which £611,474 was devoted to the payment of a 12.5% dividend. The most interesting feature of the report was, however, that of the superintending engineer, who considers that if allowance be made for the effects of the strike in July 1913 the results obtained may be considered satisfactory. The gold recovered per ton has fallen during the year from \$7.70 for the previous year to \$7.38 per ton, a decrease of 32c. per ton; but the engineer points out that the gold recovered last year more closely approaches the average value of the profitable ore reserves. The following statement shows the condition of these on December 31, 1913:

| | Tons. | Dwt. | Width. |
|--------------------------|-----------|------|--------|
| Main Reef | 392,376 | 5.1 | 60 |
| Main Reef Leader | 3,994,656 | 7.0 | 49 |
| Main Reef & Leader | 1,212,968 | 6.3 | 75 |
| Total and averages | 5,600,000 | 6.7 | 54 |

It will be remembered that under the old administration the profitable reserves, with a lower average working cost than that of today, were estimated as over 10,000,000 tons, and the engineer points out the need of increasing them, and it is in development for them that most interest centres. In 1913 no less than 56,601 ft. of work was done, developing a total of 1,530,226 tons, of which, however, only 904,046 tons, or 59%, was profitable, and of an average value of \$6.90 per ton. It is evident that in such a property as that of the East Rand Proprietary, quite double the amount of development needs to be accomplished; but there would appear to be so many difficulties to contend against in opening the 'reef' to the dip of the outcrop properties, which are fast becoming fully developed, that no surprise need be expressed at the developed ore reserve failing for the past year to come up to the tonnage milled. It will be remembered that, at the Hercules shaft, lying on the dip of the Cason and Comet vein, the Main Reef series was intersected at a depth of 4236 ft. from the surface; but the reef was unprofitable, and considerable interest centres in what will be found in continuing this shaft along the reef to the dip, where there exists a long stretch of unproved property. The advisability of a similar step being taken in connection with the western shaft of the Anjelo Deep is pointed out in the engineer's report, but this area has been somewhat disappointing at depths exceeding 4000 ft., and the driving of inclines to the dip will be watched with more than ordinary interest. It may be pointed out that the small area proved by the levels connecting the Angelo Deep shafts as also by the Hercules shaft, show a marked decrease in gold content, and unless there is a material improvement to the dip of these shafts, a considerable area must prove unprofitable. To the dip of the Driefontein property the conditions are much more encouraging. No. 27 level, west from the Angelo Deep west shaft, opening much better ground as the Wit Deep water dike is approached. Water, however, proved so abundant that a dam

had to be constructed until adequate pumping arrangements could be made, which have only just been completed. Good ore has been found in the reef wherever an abundance of water was met with, in fact, beyond the water dike running north and south, there would seem to exist a richer area perhaps than anywhere else at this depth on the Rand. Boreholes through the water dike, at depths of 3000 and 4000 ft., encountered water at the rate of 200,000 to 250,000 gal. per day, so that large pumping equipments are necessary to prove the reef beyond the water dike. At the present time, how-

PROPERTIES OF THE EAST RAND PROPRIETARY.

ever, the future of the East Rand Proprietary mines depends upon the development and opening of the country beyond the dike. There is every indication of the gold being there to pay for the extra expense likely to be incurred; but before this can be accomplished it is not impossible that the working profits of the East Rand Proprietary mines may in the interval decline.

BULAWAYO, RHODESIA

HEALTH AND DEATH RATE AT RHODESIA MINES.—ANTELOPE PRODUCTION.—THE FILABUSI DISTRICT.—COAL RESERVES IN RHODESIA.

The mining authorities of Southern Rhodesia, like those of the Witwatersrand, have of recent years made a vigorous campaign in the direction of improved health conditions. Although this subject in and on the mines is of far more pressing importance along the Main Reef of the Transvaal, the mines of Matabeleland and Mashonaland certainly have problems relative to the fitness of laborers, which demand constant attention. Happily for Rhodesia, the dread disease, miners' phthisis, which has so decimated the ranks of Rand miners, is, comparatively speaking, of little consequence. In some of the Rhodesian mines, men who are phthisical are occasionally met with, but a close investigation of these cases would probably make it clear that the sufferers contracted their malady on the Witwatersrand before they ever saw Rhodesian soil. Generally speaking, the nature of the rock in the mines of the Chartered company's territory is such, that it does not break up into the fine powder that the Rand sandstone does when drilled into. There has, however, in consequence of legislation of the Union of South Africa, been something in the nature of an influx of affected miners into Rhodesia of late. The Rhodesian Chamber of Mines, considering that a danger to the sanitary conditions of the mines was threatened, thereby advocated the restriction of employment of sufferers from this disease, and the government has introduced and promulgated the miners' phthisis ordinance, which prohibits the employment of victims of this

disease. A most gratifying feature in connection with the health conditions of Rhodesian mines, is that in regard to native labor mortality, statistics disclose a considerably lower death rate for last year than has hitherto been experienced.

During the year ended December 31, 1913, the mortality from disease was 23.69, and from accidents 4.72, giving the low total of 28.41 per 1000 per year from all causes. This compares favorably with 35.83 in 1912, and 49.27 in 1910. The most noticeable decrease was effected in pneumonia, which in 1913 caused 409 deaths, compared with 668 in 1912. While it is probable that mildness of last winter season assisted toward the diminution of disease, the main causes for the existing satisfactory death rate are undoubtedly the thorough and efficient system of medical examination of recruits, and the continued and increasing care, attention and feeding which the natives receive. A further improvement in health conditions on the mines of Southern Rhodesia is anticipated in consequence of the visit of Colonel Gorgas and his assistants from the United States, to this territory. After a short, but careful investigation, he has submitted to the administrator a most closely reasoned statement regarding malarial and blackwater fever in Rhodesia, and the best means of preventing these terrible diseases.

One of the five new and important mines of the country that have recently commenced ore treatment has already announced an initial profit of \$1500, while the cost of operation is given at the high figure of \$9.84 per ton. It is officially explained that these excessive charges were due to the low tonnage treated, caused by difficulties in connection with the new plant. Obviously it is not fair to the Company to regard the results of the initial crushing as a criterion of the capabilities of the mine, but at the same time there is some apprehension as to the future working of the Antelope equipment. At the time of writing, figures as to treatment operations at the Cam & Motor are not available; but particulars of the first month's production and the running of the new plant, which has been modeled a great deal on Kalgoorlie lines and is quite new to Rhodesia, are anxiously awaited. [The first return was 10,692 tons averaging \$7.58 per ton.—EDITOR.]

Good reports continue to come from the properties of the Hanover syndicate, a local concern, situated in the Filabusi district of Matabeleland. Of recent years there has not been much activity in this area, and the news from the Hanover is most encouraging. Until just lately development work was confined to the Tentonic vein, but work has now been decided on for the North and Hanover veins as well. In this last named orebody, a part of the vein about 200 ft. long, and assaying about \$12.50 per ton over 36 in., has been opened at the 300-ft. level. Nine dividends have been paid by this syndicate to date, and the last distribution, that for February, 1913, was 25%. Last month's output was the largest so far recorded. The prospects of this concern are admittedly bright, and the success achieved should assist in directing attention to the extensive Filabusi mining area.

An interesting bulletin has just been issued by the Geological Survey of Southern Rhodesia, dealing with the coal resources of Southern and Northern Rhodesia. Hitherto, only one colliery has produced appreciable quantities of coal, but it has been known for some time that, in addition to the deposit worked by this colliery, the Wankie in northern Matabeleland, Carboniferous measures extend over a considerable area, and it is probable that other mines will be brought to the productive stage in the near future. H. B. Maufe, director of the survey, estimates the actual reserve of coal in Southern Rhodesia at 419,317,000 tons, of which 201,200,000 tons is in the Wankie area of Matabeleland. The probable reserves, extending over a total area of 157 square miles, are estimated at a further 550,094,000 tons, making a total for actual and probable reserves of 969,411,000 tons. The majority of the coals of Rhodesia, like those of South Africa, contain a large

percentage of ash, which is high in comparison with the coals of Great Britain. However, the Wankie and one of the Tuli coals contain only 8 to 13%, which compares favorably with the usual 15 to 20% in the South African coals.

LONDON

PROSPECTS FOR OIL IN SOUTH AFRICA.—CONSOLIDATED OIL FIELDS OF SOUTH AFRICA, LTD.—REPORT BY E. H. CUNNINGHAM CRAIG.

The investigation of possible petroleum deposits in South Africa has loomed large during recent years in London circles, as well as in Johannesburg and Cape Town. Deposits have been found in Madagascar, and have been exploited by South African promoters and capital. For some occult reason, other promoters have argued that, because petroleum is found in the Jura-Trias in an island off the coast, it is also to be found in the Permo-Carboniferous and Carboniferous Devonian of the mainland. One of the companies that has noisily attracted attention is the Consolidated Oil Fields of South Africa, Limited, its very name being objectionable, seeing that it may mislead intending investors into a belief that it has some connection with the celebrated Consolidated Gold Fields of South Africa, Limited. This Company was formed to acquire a property at Ceres, in the Cape Province, about 50 miles east of Cape Town. The rocks here belong to the Cape system, analogous to the Carboniferous-Devonian age, mostly sandstones of varying character, with a few beds of shale. In no case has any geologist noted indications of the strata being petroliferous. Attention was attracted to the Ceres district by occasional outbreaks of gas. Moreover, marine fossils found in the neighborhood were supposed to be indicative of the probable presence of organic matter. Ferric hydroxide films on the water in swampy land misled investigators, who mistook the cause of the iridescent color. E. H. Cunningham Craig, the oil expert commissioned by the South African Government to report on petroleum prospects, pricked the bubble by showing that the occasional show of gas came from a buried bog, and was nothing but marsh gas. The Company, however, though expressing regret at Mr. Craig's pronouncement, fails to adopt his views, and announces its determination not to abandon the search at present. The directors state that they are encouraged to proceed by the many favorable reports on the oil possibilities of the district that they have in their possession. They state that gas has been found in the strata below the marsh. Mills Davies, of Johannesburg, is therefore continuing boring for the Company.

It is of timely interest to say something of Mr. Craig's report. He shows that traces of petroleum and allied compounds have been found in the Permo-Carboniferous, locally called the 'Karoo' beds in the Cape province, associated with and in the neighborhood of dolerite sills and dikes. In spite of extensive drilling, occasionally to great depths, nothing but 'indications' have been found. The report is in form and nature admirably adapted to requirements, suitable for readers who know little or nothing about the subject. He starts with a general dissertation on indications. He shows that, in many cases besides the Ceres, emanations of marsh gas have been mistaken for natural gas, and that the iridescent film of ferric hydroxide on the surface of swamps has often led the prospector astray. With regard to the petroleum and allied compounds in association with the dolerite dikes and sills in the 'Karoo' beds, he shows that these carbonaceous substances have been formed by the passage of the intrusive rock through coal seams and oil-shales. At no place except in a line east and west through the centre of the Cape province, where a fold in the 'Karoo' beds occurs, does the geological structure contain the anticlines and domes so often associated with petroleum accumu-

lations. Mr. Craig is not hopeful, however, of favorable results following boring in the region of this fold. The possibility of petroleum having been found in the neighborhood of salt pans is also adversely discussed. He shows that these are the accumulations during geologic ages of the denudation of a country continuously above the sea, and that in many cases fresh water can be obtained from wells in their vicinity. Thus the salt has no connection with the brine and rock-salt so often found in conjunction with petroleum. Mr. Craig describes the oil-shales in the Ermelo district in the eastern Transvaal, and in the Drakensberg range in Natal. Owing to the thinness of the seams at Ermelo, none being much over a foot wide, it would be impossible to mine them at a profit. On the other hand, the Natal deposits are more hopeful, and he recommends that they should be tested on a large scale. As to natural gas, he is of opinion that in many places accumulations would be found under dolerite sills that might afford small local supplies for lighting purposes. Altogether, Mr. Craig's report presents a hopeless sort of outlook, and it has caused many bad attacks of grouchiness.

CHISANA, ALASKA

DESCRIPTION OF THE GLACIER TRAIL AFTER LEAVING SHUSHANNA JUNCTION.—WORK DONE IN THE WINTER.—COST OF FREIGHTING AND FOOD.

A week's inspection of this new placer-mining district left the following impressions: The trail from McCarty over the Nizina and Chisana glaciers, which so far has proved the best winter route, though at best it is a hard pull, was taken. From McCarty, renamed Shushanna Junction by the railroad peo-

commission ought to have an emergency fund at its disposal, that would enable it to place a couple of men on such a trail to keep it safe to travel over. Once past these eight miles, which part is about five miles from the summit, it is all clear going, with only an occasional rough place. From the foot of the glacier it is about six or seven miles across the river, and through the woods to the town, all easy traveling over the ice.

Actual information about the camp is almost as lacking as it was last September. This is due to a number of causes. In the first place, many of those who got in on the known ground, went outside for the winter, and have just returned, and their ground has not been prospected. In many other cases, probably 75%, the holes have encountered water before they reached bedrock, so the only thing the prospector could do was to wait till the spring and commence sluicing. A large portion of the claims are above timber line, and the men have worked like slaves 'necking' up wood to thaw down the holes. A few boilers have been taken into the district, but little work has been done with them so far. Most of the shorter creeks have steep gradients and flow through narrow cañons.

Freight fell to 10c. per pound during the spring when the trail was at its best, but will go up rapidly when the trail breaks up. Meals are \$2 each, but worth it as the food is good. Wages will probably be \$6 or \$7 per day with board; but with the number of prospectors in the district looking for work to continue prospecting, it would be a poor place for anyone to come to 'rustle a job'. Actual cash is scarce, and probably many of the outfits will work 'on bedrock.'

A map in the U. S. Geological Survey bulletin on the Nebesna-White River district shows the general contour of the Chisana area. Chavolda creek, on the map, has been changed to Wilson creek; and Chatnenda to Johnson.

WASHINGTON, D. C.

SMOOT BILL PASSES THE SENATE; NOW IN THE HOUSE.—IMPORTANCE OF THE MINING INDUSTRY.

The Senate has passed the bill providing for the codification of the federal mining laws, and it now remains for the House to act. The bill passed in the Senate without opposition or debate, Mr. Smoot, Senator from Utah, directing its course. It provides for a commission of three members instead of five, as had been hoped by certain mining people. Senator Smoot made no attempt to amend his measure on that score, although offering several amendments, which the Senate accepted, relating to other provisions in the bill. Instead of providing a commission which shall be composed of a member of practical experience in the operation of mines, a lawyer of experience in the practice of mining law, and a member connected with the U. S. Geological Survey, the bill as passed by the Senate was amended to provide a commission to be appointed by the President and confirmed by the Senate, two members of which shall be lawyers of considerable experience in the practice of mining law, and one a mining engineer who shall have had practical experience in the operation of mines. No miner is provided for.

While the Senate passed its bill, the House committee on mining reported out to the House the Taylor bill, providing for a similar commission, but differing in its terms. It provides for a commission of five members, and carries no salary. The House committee has learned that persons who favor the commission are willing to provide their services free. Inasmuch as the House committee is quite a pro-labor body, it may be expected to work hard for a member who shall be a miner. It is expected that the differences between the two bills will be adjusted in a conference committee between the two houses when the House shall have

MAP OF THE CHISANA DISTRICT, ALASKA.

ple, there is a good river trail to the foot of the glacier; but once on the glacier there is a continual ascent for about 25 miles, reaching an altitude of about 9000 ft. Although a large portion of the trail is not excessively steep, practically all of the freight was being relayed in, and at the steepest pitch a 'Brunton' gave a reading of 25°. At this point the carriers were only loading 250 lb. on the sleds, as that was about the limit of the average horse.

On the Chisana side the glacier is far more active, and for eight miles of the trail it is as much as a man's life is worth to step out of the beaten trail. This distance has been the hardest on the freighters, as about 25 or 30 horses have been lost in the crevasses, and a number of men have fallen in, but somebody has been there to pull them out. Many of the crevasses have been bridged by poles brought up by the freighters, but they are poor makeshifts. It seems as if the road

passed its own version. As things now are, the House will take the Senate committee bill from the Speaker's desk and amend that; the conference committee will do the rest. It is probable that the House will insist on a committee of five members. The House bill carries the provision that the code shall not deal with lands containing deposits of coal, oil, gas, phosphates, or soluble potassium salts, and with that amendment it is acceptable to the Department of the Interior. In reporting out the bill, the House committee on mining said:

"The essential features of the general mining laws of the United States were determined over 40 years ago, when the total production of mineral substances in this country did not amount to more than \$300,000,000 per year. Since that time the value of the total mineral output has increased to \$2,250,000,000 per year, a sevenfold increase. This growth has in part resulted from the discovery and utilization of many mineral substances not previously known to be of any economic value. Since these substances were not within the purview of the original law, no provision was made for their development, and only through the use of strained and forced constructions of the law has it been possible to develop such deposits at all. Of all the defects of the general mining law, the most serious is the present uncertainty of title of a locator to the mineral land he claims. This works an especial hardship on the prospectors and men of small means by whom the discoveries of new mineral deposits are chiefly made. The vital importance of this matter is not alone measured by the 2,300,000 men engaged in the mining industry, and the value of products which results from their labors, but rather by its effects on the whole of the people. More than half the freight hauled by the railroads is the product of the mining industry, and of the \$20,000,000,000 worth of manufactured products annually produced in this country, almost the whole involves the employment of metallic mineral substances. The committee believes that this bill will meet with the hearty approval of prospectors, miners, operators, and the people generally everywhere, and it is sincerely hoped that it will pass."

BRUSSELS, BELGIUM

IMPROVEMENTS AT KATANGA, CENTRAL AFRICA.—AMERICAN ENGINEERS EMPLOYED.

The Union Miniere Du Haut-Katanga is making big plans. An important extension to the smelter has been decided upon. R. M. Johnson, of the East Butte Mining Co., Montana, has been engaged as manager at Kambove. He left for the Katanga at the end of April. The Company will soon have two steam-shovels at work at Kambove, and has already two at work at the Star mine. Mr. Wheeler, consulting engineer, left for the Katanga early in May. F. W. Snow has been engaged by the Union Miniere for mill and smelter experimental work. F. D. Kehew, of the Cananea Consolidated Copper Co., Sonora, has been engaged as smelter superintendent at Lubumbashi. These men will leave soon for the Katanga. The Company has signed an important contract for Nyassaland labor, and several hundred boys have already been recruited. With Horner, Wheeler, Snow, Johnson, and Kehew on the job the Union Miniere should soon get good results. The Company is going into the work in a big way and one can expect some progress from now on comparable with the importance of the copper deposits of the region. It speaks well for American engineers that a Belgian-English company should put its future entirely into their hands. The Brussels company just received the third shipment of about 5000 carats of diamonds from the Kasai field. Among them is a 14-carat stone of good quality. Mining operations at Katanga have a brighter aspect at the present time than at any period in the past, and results are expected soon.

NEW YORK

EFFECT OF THE RECENT DECISION ON FLOTATION PATENTS.—ANACONDA IN 1913.—GREENE CANANEA DIVIDENDS.

The announcement of the handing down of the court's decision in the Butte Superior and Minerals Separation flotation suit has, of course, been the topic of interest of the week. Statements from the two parties to the suit have appeared, and there has been considerable discussion of its effect. The Butte & Superior is relieved by it of the payment of big royalties as well as of large sums for the tonnage which it has treated already. Aside from this Company, however, the situation actually seems to be much the same as it was before the decision was brought, because of the peculiar fact that in our patent law one court is not bound by another's decision in a patent case. As the Minerals Separation Co. has been fighting its patents for two decades in Australia and England, and has carried its suits up to the House of Lords, it can be taken for granted that a single adverse decision in this country is not going to end the matter with them, and they no doubt would like nothing better than an early opportunity to start a suit in another one of the 96 district courts. It will, of course, leave no stone unturned to bring the suit, if possible, before the Supreme Court of the United States, though this is a rather difficult matter to do. Probably the net result of the adverse decision will be to cause the Minerals Separation to demand more modest royalties in order to encourage people to pay them rather than defend infringement suits. As a matter of fact, any small company where the amount of royalty in a year would not amount to very much, would be a great deal better off in paying the royalties demanded, and getting the coöperation of the Minerals Separation staff, than it would in trying to develop its technique alone and fight an infringement suit.

The Anaconda has issued its report for last year [this will be published in the next issue of this journal], and the lessened output and the decreased net earnings have been made the most of in the market. There is a deficit of over \$1,500,000 in the net earnings for the year as compared to the dividends paid, but as the Anaconda has a surplus of about \$9,000,000 this is not a serious affair. During most of last year the copper market looked weak, and it was obviously not the time to make any great attempts to increase output except on the part of the companies which were able to make copper at the lowest cost figure. The Anaconda was engaged in making many changes in its procedure, and quite naturally utilized this period when economic conditions seemed to call for a slightly lessened production. Important changes are on the way in the milling and smelting plant.

For the new leaching plant to be erected by the Utah Copper Co. it is understood that the sulphuric acid needed for the process will be produced at the Garfield smelter, where a chamber process acid plant will be built.

Two weeks ago it was noted that the Greene Consolidated and the Greene Cananea had postponed action on dividends on account of the uncertainty of the situation in Mexico. Meanwhile the operating staff at Cananea has been withdrawn and then sent back again, so that the work is now under way. The Companies have therefore declared quarterly dividends of 50c. per share, and judging from advices from Mexico, Cananea ought to be able to operate at approximately its normal rate. Greene Consolidated, it will be remembered, is the Company which owns the Cananea Consolidated Copper Co., which operates the mines and smelters. Practically the whole share issue of the Company is owned by the Greene Consolidated Copper Co., capitalized at \$60,000,000, and is the only Company in which the public owns shares.

At Nacozari, operations have been resumed, while at the Tigre and several others of the mines in the north, work has not been interrupted. Recent reports from Pachuca, El Oro, and Guanajuato are discouraging.

General Mining News

ALASKA

The lignitic coal reserves of the Bonni field, Alaska, are estimated by the U. S. Geological Survey to be nearly 10,000,000,000 tons, which exceeds by nearly 3,000,000,000 tons the estimate made a few years ago, on the information then available, of the total quantity of lignitic coal in the territory. The new estimates, which are very moderate, indicate that the quantity of coal available in the Bonni field is greater than that of all the other surveyed fields of the territory.

CHISANA

Reports on this new placer district vary considerably, as is shown by the following notes and also in the 'Special Correspondence' pages of this issue: Larry Peppard arrived at Dawson on April 24. He said the trail was good, no new discoveries have been made, prospecting is still under way, the hauling of wood is difficult, and Bowen creek, on the Canadian side, is promising. John Raymond also arrived at Dawson. The trail was good. The camp is an uncertain quantity, according to his statement. Outside of the Bonanza and Little Eldorado gravels, little has been found. F. T. Hamshaw has six boilers and 20 men at work prospecting, and has gone to Cordova to complete a deal with Manley and Ives. There are from 400 to 500 people in the district. Supplies are plentiful. Eggs are \$1 per dozen, and a good meal costs \$1. Last, but not least, the saloon at Johnson City will be closed if the camp does not improve, the owner, F. Miller, being dissatisfied with prospects.

ARIZONA

COCHISE COUNTY

(Special Correspondence.)—After being shut down for 14 years, the Cochise Copper Co.'s property, two miles north of this place, is to be reopened. For this purpose the Southwestern Copper Co. of San Simon, has been incorporated. A good deal of equipment has remained on the surface all this time, and is in fair order.

Paradise, April 30.

At 1800 ft. in the Junction shaft of the Calumet & Arizona a large station is being cut. Large electric pumps are to be installed here when it is finished. The present flow of water in this shaft, 1500-ft. level, is 3000 gal. per minute, so manufacturers of pumps will have an opportunity of bidding for a large plant later on.

GILA COUNTY

(Special Correspondence.)—Twelve vertical raises have been started from the 600-ft. level of the Inspiration mine. A total of 48 faces are being worked in ore throughout the mine. Concreting the main east shaft station on the 400-ft. level is nearly completed, and with this in place the shaft work will be resumed, 40 ft. of it already being done. A 6 by 20-ft. tube-mill was installed at the test-mill during the week, and will be started within a few days. A 66-in. Bradley mill also is soon to be tried at the experimental plant for the purpose of comparing its efficiency as a fine crusher with several other types of mills which have already been given exhaustive tests. The type of bin to be used at the new concentrator is of the suspension class. It will run the entire length of the mill and will have an available capacity of 12,000 tons, or 2000 tons per mill unit.

Development at the Miami mine during April totaled 4937 ft. Masses of chalcocite and carbonate ore have been opened in a shattered zone of the Independence mine in the Miami district.

Miami, May 7.

The 6 by 20-ft. tube-mill which is to be used in the above test is a Chalmers & Williams adjustable quick-discharge machine, described in this journal on page 1040 of the issue of December 27, 1913.

The Inspiration company will install new station equipment consisting of three 6000-kw. Curtis turbo-generator units with 45-kw. exciters. The contract for the apparatus has been awarded to the General Electric Company.

MARICOPA COUNTY

(Special Correspondence.)—Two engineers of the U. S. Geological Survey are to examine the cinnabar deposits in the northeast corner of this county. A good deal of development has been done on them. Four feet of good gold ore has been opened in the Old Kentuck mine, 20 miles south of Phoenix, by John White. This is in a promising district. At the Max Delta mine, the main incline shaft is down 400 ft., and will be sunk to 500 ft. Sixteen men are employed. Ten stamps are being added to the Goldfield mill, near Mesa Phoenix, May 2.

MOHAVE COUNTY

The State Tax Commission has just made its report to the assessor of this county on account of mine tax for the year 1914. Owing to the large amount of dead work done by the Golconda last year and the stoppage of production by reason of the sinking of the new shaft to the 600-ft. level, and overhauling the old shaft to the surface, there was no net production from that property, according to the *Mohave County Miner*. The same was true of the Grand Gulch and the Frisco Gold mines. This left only three corporations in the county that paid net on their production, the Gold Road, Tom Reed, and Needles Mining & Smelting companies. The following is the production of these corporations as shown on the tax roll:

| | Gold Road, ounces. | Tom Reed, ounces. | Needles, ounces. |
|--------------|-----------------------|----------------------|---------------------|
| Gold | 31,875 | 52,538 | 1,370 |
| Silver | 14,246 | 25,697 | 101,577 |
| | | | Pounds. |
| Copper | | | 16,568 |
| Lead | | | 4,266.250 |
| Zinc | | | 3,984.604 |
| Value | \$667,375 | \$1,101,748 | \$503,061 |
| Net | 83,876 | 789,759 | 33,663 |

YAVAPAI COUNTY

(Special Correspondence.)—The old Sunset mill is to be overhauled by W. Sisson, who will treat custom ores Harrisburg, April 30.

CALIFORNIA

Section director Cole, of the U. S. Weather Bureau, with headquarters in Reno, Nevada, has made measurements of snow in the Sierras and finds considerable snow there for this time of the year. The deepest drift was 225 in., and there were many others ranging from that depth down to 53 in. At the measuring station the snow was 63 in. deep. There was practically none on the south slope of the range.

BUTTE COUNTY

A bond upon the property of W. P. Lynch in Sawmill ravine near Pentz has been taken by O. C. Perry and R. S. Kirrick. They have sent a Keystone drill there to prospect the land for gold. If results are satisfactory, a dredge will be constructed there. It is known that much amalgam escaped from the sluice-boxes at the old Cherokee hydraulic mine.

An English syndicate has bought shares worth \$30,000 in the Nimshaw Ridge Mining & Development Co., 18 miles south-east of Chico.

ELDORADO COUNTY

The old Union mine, 11 miles south of Placerville, which has been opened to 1600 ft., has a 60-stamp mill and other equipment, and has been shut down for seven years, has been

A magnetic separating plant is in full operation at the Success mill, treating concentrate. This product is dried in a revolving tube, 3 by 30 ft. and then treated by four

New Century magnetic machines, which now produce a 46% zinc product. C. C. Samuels is superintendent of the mill.

The Hercules Mining Co. has driven its No. 5 or Hummingbird adit a distance of 8185 ft., and has cut 25 ft. of ore. Profits of this Company in 1913 were \$1,207,326. Work has been resumed at the Polaris mine after several years of idleness. The faulted vein in the Snowstorm mine has been found again.

Mining operations on Pine creek are beginning for the summer, and several properties have started work, including the Spokane group, International Crown Point, and Odd Fellow group.

MICHIGAN

HOUGHTON COUNTY

The Tamarack Mining Co. has decided to erect a re-grinding and leaching plant to treat its current and old sand which has accumulated in Torch lake for 30 years. The plant will cost about \$250,000. Mining operations have been resumed at the Tamarack, conditions being fairly good for regular work. On May 6 the Carroll foundry at Houghton was destroyed by fire. The loss is between \$500,000 and \$600,000, of which \$400,000 was in valuable patterns. The insurance was \$250,000. The plant has been in operation for 21 years.

MISSOURI

JASPER COUNTY

Zincblende containing 60% metallic zinc ranged from \$40 to \$35 per ton, during the week ended May 2, according to Lucius L. Wittich in the *Joplin News Herald*. There is a stock of about 15,000 tons of unsold ore in bins. Calamine was in fairly good demand at \$19 to \$20 per ton, basis of 40% metallic zinc. Lead ore was stronger at \$46 per ton, basis of 80% metal. Shipments for 18 weeks of the current year were: blende, 172,233,198 lb., worth \$3,422,739; calamine, 11,675,250 lb., worth \$125,182; and lead, 32,316,130 lb., worth \$755,676. The first turn-in from the Boston-Aurora mine has been made. The mill has a capacity of 100 tons per shift. Ore occurs at a depth of 180 ft. In April, the Continental Zinc Co., of Cartersville, produced 318,000 lb. of blende and 223,000 lb. of lead concentrate, working single shift. The mill can treat about 400 tons of ore per shift. Sheet ore, at 190 ft. in the Bippo, west Joplin, is being worked. Two developments of rich galena and blende were made in the Lone Elm lease of the Granby company's land at 95 ft. A flotation plant is being installed at the Priscilla mine, west of Joplin, by G. S. Thomas and D. I. Hayes. The ore is typically sheet ground, containing 58% blende. The sludge is to be treated by this process.

MONTANA

Billings car No. 5, of the U. S. Bureau of Mines, will be at the Bear Creek, Montana Coal & Iron, and International Coal companies' mines, Bear Creek, from May 25 to 30; at the Anaconda Copper Mining Co. and Smokeless and Sootless Coal Co. from June 1 to 6, and at the Northwest Improvement Co., Red Lodge, from June 8 to 13.

LINCOLN COUNTY

A great deal of preparatory work has been done at the gravel areas at Libby, and good returns are expected before long.

SILVERBOW COUNTY

From 4 to 5 ft. of 30% zinc ore is reported to have been opened at 2200 ft. in the Pilot-Butte mine. Copper has also been opened on this level.

NEVADA

ELKO COUNTY

After the expiration of the option on the Elko Prince mine at Midas, it will be taken over by the old company

the estate of W. C. Savage having the largest interest. A test run is being made in the cyanide plant of the Rex, nearby on the south, also samples are being tested in San Francisco. It is hoped at an early date to have enough data to let a contract for the plant. The mine has sufficient high-grade ore in one shoot to supply a 35-ton mill for four years or more.

LYON COUNTY

The annual report of the Mason Valley Mines Co. for 1913 shows that 228,855 tons of ore was smelted, of which 116,636 tons was from the Company's property and 111,219 tons from custom ore. Matte produced was 17,166 tons, containing 14,601,520 lb. copper, 9922 oz. gold, and 121,835 oz. silver. The profit was \$120,564, and the balance from 1912 was \$226,897, making available the sum of \$347,461. Charges against this totaled \$259,325. The smelting capacity is now 1800 tons of ore per day in two furnaces. The general manager, Jules Lebarth, has arranged with the Southern Pacific railroad to haul 100 tons of ore per day from the Balaklala mine, California, to the smelter.

NYE COUNTY

The two Packard auto-trucks have so far proved a great success in hauling ore from the Reilly Fraction open-cut to the War Eagle mill at Manhattan, a distance of 1.9 miles per round trip. The average loads are from 6 to 7 tons, and the time per trip is about a half-hour. The loaded cars run by gravity to the foot of the War Eagle hill, so that the gasoline consumption amounts to less than 1 gal. per trip. The cars keep the mill supplied with about 250 tons for each day's crushing, and the cost of transportation per ton is less than one-third of the cost when horses were used.

The main gulch at Manhattan continues to be the scene of active placer operations, and the yield is said to average from \$4 to \$6 per yard. A nugget worth \$108 was recently found in the Polaris ground. Other good nuggets have been recovered.

The annual report of the Dexter White Caps Mining Co., of Manhattan, gives the following information: On November 15, 1913, the Company took over the property from the White Caps Leasing Co. Cross-cuts and shaft-sinking have since been done at respective costs of \$7.59 and \$19.48 per foot. There are three well defined lodes in the mine, and reserves total 16,679 tons averaging \$14.35 per ton. During 1913 the output was 3555 tons of \$24.30 ore. Royalties received totaled \$6584; balance from 1912, \$9235; and cash at end of 1913, \$9374. A sum of \$1674 is due from the leasing company. It is proposed to consolidate the Associated mill, the White Caps Leasing Co.'s equipment, and the property of the White Caps Mining Company.

The western ore zone of Tonopah has revealed some good developments, and is attracting considerable attention of late. This is especially so in the Extension at 1100 ft., Victor at 1500 ft., Merger at 1170 ft., and also in the Cash Boy. The output of the district during the past week was 11,379 tons of ore, worth \$278,680.

WHITE PINE COUNTY

During the first quarter of 1914 the Giroux Consolidated company produced 20,428 tons of ore yielding copper worth \$79,157, at a cost of \$93,136.

The Nevada Consolidated reports as follows for the first quarter:

| | |
|---|------------|
| Overburden moved, cubic yards | 906,097 |
| Ore milled, tons | 792,754 |
| Copper production, pounds | 15,597,592 |
| Earnings from mine, etc. | \$ 801,441 |
| Dividend No. 18 | 749,796 |
| Undivided profits | 2,892,599 |
| Metals at refinery and in transit | 2,690,958 |
| The output was 1,087,363 lb. less than the preceding quarter. | |

NEW MEXICO**GRANT COUNTY**

During the first quarter of 1914 the Chino Copper Co. reports the following results:

| | |
|--|------------|
| Overburden moved, cubic yards | 938,590 |
| Ore mined, tons | 606,990 |
| Ore milled, tons | 582,200 |
| Copper, per cent | 2.18 |
| Copper production, pounds (including 798,450 lb. from ore smelted) | 18,078,128 |
| Extraction, per cent | 68.05 |
| Total profit | \$812,087 |
| Dividends paid | \$645,405 |
| Copper on hand and in transit (sold and unsold), pounds | 23,444,209 |

There was an all-round improvement compared with the previous quarter. First-mortgage bonds worth \$112,000 were retired.

(Special Correspondence.)—The Oaks Co. holds an option on the Eberle mine and has ordered the necessary equipment for development. Some good ore is showing about 300 ft. in a cross-cut, and work will be started there. A survey has been completed for an aerial wire-rope tramway to properties about one mile distant, upon which the Socorro Mining & Milling Co. holds option to purchase. The mill handled 5000 tons of ore in April and shipped over 2 tons of bullion, in addition to several tons of high-grade concentrate. Dividends of 1% per month are paid on the common stock, the preferred issue being retired from earnings several months ago. This and the Ernestine company are producing over \$2000 per day each.

Mogollon, May 4.

OREGON

The geology and mineral resources of the John Day district, situated in the north central part of Oregon, is described by Arthur J. Collier, in the March issue of 'The Mineral Resources of Oregon,' published by the Oregon Bureau of Mines and Geology, at Corvallis. The area contains coal, limestone, building stone, slate, basalt, chromite, copper, gold and silver, and artesian water.

SOUTH DAKOTA

The 'Minerals of the Black Hills,' by Victor Ziegler, is the subject of *Bulletin 10*, published by the South Dakota School of Mines at Rapid City. It consists of 250 pages, and is well illustrated by halftones, maps, and charts. There are 300 minerals described, as occurring in this area, many of them being rare species. The total production of gold, the most important product of the Black Hills, amounts to about \$180,000,000.

UTAH**JUAB COUNTY**

The North Tintic district is more active than for some time past. A small cave was recently opened above the 400-ft. level of the Iron Blossom at Tintic, and good ore is showing.

SALT LAKE COUNTY

The Utah Copper Co. reports as follows for the first quarter of 1914:

| | |
|--|-------------|
| Capping moved, cubic yards (March record, 608,517 cu. yd.) | 1,519,940 |
| Bingham & Garfield Railway, average per day, tons of ore | 16,399 |
| Ore milled at Magna and Arthur plants, tons | 1,962,100 |
| Average copper content, per cent | 1.3411 |
| Copper production, pounds | 32,846,155 |
| Net profit from mills, rents, dividends, etc. | \$1,965,074 |
| Dividends paid | 1,189,440 |
| Surplus for quarter | 775,631 |

Wet and frozen ore interfered with the regular mining and milling, but although the tonnage milled was lower, the yield was higher than the last quarter of 1913.

SUMMIT COUNTY

The Snake Creek adit was driven 314 ft. in April. The flow of water is now 5000 gal. per minute. An 18-in. air-pipe is kept within about 100 ft. of the face of the adit, and operating by suction quickly clears away the smoke and gases after each shot. After connection is made with the Daly-Judge workings, this pipe will not be needed for air, but can be used to help take care of any flow of water that may exceed the capacity of the ditch, which is 12,000 gal. per minute. It is estimated the pipe would carry, with suitable head, 10,000 gal. per minute.

Good progress is being made with the erection of the plant for the Park City Milling Co. A number of tanks have been shipped from San Francisco by the Mine & Smelter Supply Co. G. H. Scibird is in charge of construction.

WASHINGTON

A Bureau of Mines rescue car, for mine rescue and first-aid training, from the Seattle station, J. J. Corey, foreman, will be at Fairfax from May 11 to 16, Seattle from May 16 to 24, and at Roslyn from May 24 to June 4. Billings car No. 5 will be at Spokane for repairs from May 18 to 23.

OKANOGAN COUNTY

A vein from 16 to 20 ft. wide, containing lead and silver, averaging \$7 per ton, has been opened for a good distance in the Caaba mine, near Oroville. Below this the ore contains 5% of copper. The shaft is being sunk to 1000 ft. The property is under option to the United Mines Co. There is a 20-stamp mill near this mine, also 10 stamps and a 60-ton electrically driven Morris pulverizer on the Owasco group, held under option, five miles distant.

SPOKANE COUNTY

Dealings on the Spokane Stock Exchange in April, in 36 different mining companies in Idaho, Washington, and British Columbia amounted to 392,490 shares worth \$67,995.

STEVENS COUNTY

Smelter returns from the Grand Forks plant, on 33 tons of ore from the United Copper mine at Chewelah, amounted to \$3290 net. The ore averaged 20% copper, 174 oz. silver, and some gold. A raise is being driven in the new shoot, and should connect with the upper workings about the middle of June. An output of 200 tons of ore per day is expected when this is through.

CANADA**BRITISH COLUMBIA**

Copper weighing 122 tons has been shipped from the Granby company's new smelter at Hidden Creek to New Jersey for refining. This is the first return. Between 700 and 800 men are employed at the mine and plant. The Grand Forks smelter treated 101,153 tons of ore in April yielding 1,692,102 lb. copper, and for the first four months of 1914, 401,246 tons of ore yielding 6,900,652 lb. copper.

ONTARIO

The richest shipment of silver ore for the current year from Cobalt has recently been sent to Saxony, Germany, from the Crown Reserve mine. Twenty tons will average about 4000 oz. per ton, worth a total of \$50,000. From 125 to 150 tons of ore is being sent daily from this mine to the Dominion Reduction mill. The shareholders of the Chambers-Ferland company recently had a stormy meeting at Cobalt. Prospecting by hydraulicking has been started for the season at the Nipissing mine. At the Dome, the main shaft is down 514 ft. Additions to the mill should be finished at the end of the current month.

Personal

E. B. KIRBY is in New York.
H. FOSTER BAIN has gone to New York.
M. H. KORYLA has returned from Costa Rica.
E. M. HAMILTON is returning from San Salvador.
KARL EILERS was in San Francisco on Monday.
CHARLES BUTTERS is in the hospital in New York.
KIRBY THOMAS is in Virginia on professional work.
F. F. SHARPLESS was in San Francisco over Sunday.
S. W. AUSTIN has gone to Washington and New York.
ALFRED VON DER ROEP left New York for California on May 8.
ALFRED JAMES is expected in New York on his way to Canada.
A. W. GEIGER has resigned as manager for the California Ore Testing Company.
C. R. VAN ARSDALE has gone to Arizona, expecting to return to New York within a month.
H. W. ALDRICH, who has been visiting smelters in the South was in San Francisco this week.
C. E. BUNKER is manager for the Oroya Leonesa, Matagalpa, Nicaragua, succeeding H. W. COE.
L. D. RICKETTS has been elected a director of the Inspiration Consolidated Copper Company.
A. C. H. GERHARDI, formerly of South Africa, is with the Iron Mountain Copper Co. in charge of engineering operations.
W. A. HAYWOOD is at Aroa, Venezuela, superintending the blowing in of the smelter of the South American Copper Syndicate.
MORTON WEBBER is in Idaho on examination work. His other professional engagements will make his return to New York indefinite.
SUMNER S. SMITH and WILLIAM J. MALONEY, the federal and territorial mine inspectors of Alaska, recently visited the Goldstream district and report very little activity at present.
H. C. H. CARPENTER, professor of metallurgy at the Royal School of Mines, London, has been in San Francisco, and is to visit Tonopah, Goldfield, Butte, Houghton, Colbalt, and Porcupine. He has already studied metallurgical methods at Cripple Creek and in Utah.

Obituary

NEWTON H. WINCHELL, geologist, and archeologist, was born at North East in Duchsess county, New York, on December 17, 1829. He received the bachelors degree from the University of Michigan in 1866 and in 1869 the master's degree. Upon graduation he became the assistant state geologist of Michigan, and in 1870 was appointed to the same position for the state of Ohio. In 1872 he became the state geologist of Minnesota, which position he held until 1900. In 1906 he was appointed archeologist for the Minnesota Historical Society. Among his many attainments in the course of a long and useful professional career may be mentioned his membership on the U. S. Assay Commission in 1887; founder and editor of the *American Geologist*; fellow in the A. A. A. S.; president of the Geol. Soc. of America; member of Soc. de Min. Francaise; Soc. Geol. de Belge; American Anthropol. Assn.; Minn. Acad. of Science, of which he was a founder and three times the president; N. Y. Acad. of Science; Washington Acad. of Science; Am. Geol. Soc.; and many other scientific organizations. His writings on geological subjects in some of which he collaborated with his sons, Horace V. Winchell and Alexander N. Winchell, will be remembered as valuable additions to the literature. His death, which occurred last week, will be mourned by his many friends and colleagues in the field of science.

| Zinc dust, 100 kg. zinc-lined cases, 7½ to 8c. per pound. | |

EASTERN METAL MARKET

(By wire from New York)

NEW YORK, May 14. There has been little movement in copper, although it shows a slight upward tendency. Lead and spelter are quiet but steady. Copper shares are strong, business being done in Utah Consolidated, Chino, Nevada Consolidated, and Tennessee; Amalgamated moved slowly, but Anaconda was neglected. Generally there was dullness on 'Change. Trouble on the London market has affected business somewhat. Tin is firm at 33 7/8 to 33 9/16, in New York, and antimony dull at 7.15 to 7.25c. In London, copper is quiet at £63 2s. 6d to £63 12c. 6d., tin at £153 5s. to £155 2s. 6d., and spelter £21 7s. 6d. Bar silver is 26 9/16. Mining in Mexico is further curtailed, according to reliable reports of Americans who have left Pachuca, El Oro, and Guadalupe.

SILVER

Below are given the average New York quotations in cents per ounce, of fine silver.

| Date | Average week ending |
|------------------|---------------------|
| May 7..... | 58.75 |
| " 8..... | 58.81 |
| " 9..... | 58.87 |
| " 10 Sunday..... | 58.30 |

German consumption of foreign copper during the first quarter of 1914 was 32,600 tons, against 14,355 tons in the same term of 1913. Of the present year's consumption, 48,399 tons was reported from the United States.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

| Week ending | Apr. 30. |

TIN

New York prices control in the American market for tin, since the metal is almost entirely imported. San Francisco quotations average about 5c. per lb. higher. Below are given average monthly New York quotations, in cents per pound:

Monthly averages.

| 1913. | 1914. | 1913. | 1914. |
|------------|-------|-------|-------|
| Jan. | 50.45 | 37.85 | 40.70 |

April tin statistics were as follows, according to L. Vogelstein & Co: supplies from all sources, into Europe and the United States, 8265 tons; deliveries, 9858 tons; visible supplies, landing and in transit, 16,597 tons; average price per pound in New York, 36 11/16; and in London, £218 10s. to £231 10s. per ton.

COPPER PRODUCERS' ASSOCIATION REPORT

The Copper Producers' Association statement for April shows an increase in production and increase in stocks on hand. The details are as follows:

| | Pounds. |
|---|-------------|
| Stocks of marketable copper of all kinds on hand at all points in the United States April 9, 1914.. | 64,609,319 |
| Production of marketable copper in the United States from all domestic and foreign sources during April | 151,500,531 |
| Deliveries for consumption, April..... | 63,427,633 |
| Deliveries for export, April..... | 82,345,216 |
| Stock of marketable copper of all kinds on hand and at all points in the U. S., May 2..... | 70,337,001 |

Recent changes in surplus have been as follows, in pounds:

| Increase. | Decrease. |
|--------------------|------------|
| April | 28,720,162 |
| May | 8,074,883 |
| June | 14,569,619 |
| July | 699,320 |
| August | 15,280,908 |
| September | 8,531,043 |
| October | 2,773,288 |
| November | 15,363,047 |
| December | 43,509,438 |
| January 1914 | 4,112,182 |
| February | 8,934,833 |
| March | 11,615,531 |
| April | 5,727,681 |

Production of Ural district of Russia amounted to 1,000,000 pounds of copper per short ton in 1913, an increase of 200,000 pounds over 1912. The demand for this product is heavy from foreign countries and the output is increasing.

ORE MILLED on the Rand in March was 2,094,098 tons averaging \$6.32, and cost \$4.14 per ton for all operations. The total profit was \$4,650,000.

Gold worth \$1,000,000 was shipped from San Francisco to the Philippines on May 5. This is the first movement of gold to this territory for several years.

OPERATIONS at the U. S. Assay Office in New York in April totaled \$2,862,086. For the first four months of the current year the business amounts to \$27,712,248, against \$34,283,992 for the whole of 1913.

Production Statistics

Final figures of mineral production of the various states in 1913 are being collected, and the U. S. Geological Survey has published the following data regarding the central states, as compiled by J. P. Dunlop:

ARKANSAS

The value of the mine output of lead and zinc in this state was \$55,120, compared with \$106,014 in 1912. None of the concentrating plants in Arkansas were in active operation during 1913, and the ore shipped was either hand-cobbed or recovered by hand jigs. Nearly all the mixed sphalerite and carbonate was mined by J. Conness Shepherd at the Red Cloud, Climax, and Morning Star mines, in the Rush district, Marion county. The Morning Star mine was also the largest producer of high-grade zinc carbonate. The Frisco and Gloria mines, in the zinc district, Boone county, were worked steadily by L. L. Brown, and the output was the second largest in the state. The small lead shipments were made by the Washington Mining Co., of Washington county, J. W. Park, of Marion county, and N. B. Whitely of Newton county.

ILLINOIS

The value of the silver, lead, and zinc produced at mines in 1913 was \$336,963, compared with \$679,259 in 1912. Shipments of silver-bearing galena concentrate from the southern Illinois fluorspar region amounted to 507 tons, or 290 tons less than in 1912. The decrease in output was due chiefly to the flooding of the Rosiclare mines, the largest producers of lead concentrate in the region, though the Fairview mine also reported smaller shipments of galena in 1913. The lead concentrates yielded an average recovery of 7 oz. of silver per ton. With the exception of one mine in the Elizabeth district, which produced a small quantity of galena, the mines near Galena were the only producers in northwestern Illinois. Development work was more active than in previous years and several mines were placed on a productive basis in the latter part of the year, so that the output in 1914 will probably be much larger than in 1913.

The Vinegar Hill Zinc Co. operated the Vinegar Hill, Eadie, and Marsden Black Jack mines, but the Unity mine, a large producer in former years, was not worked. The old Marsden Black Jack was opened again, and the property was equipped with a 200-ton plant, which was in operation during the past three months of 1913. The Northwestern Zinc Co., was a large producer of both lead and zinc, and the Great Western Lead Manufacturing Co., developed a new mine on the Brown land

and moved the Calvert mill from Benton. Lead and zinc concentrates were sold by the Ten Strike, Josephine, Betsy, and Glen Ridge mines.

KANSAS

The value of the lead and zinc produced at mines in Kansas was \$1,343,432, compared with \$1,680,744 in 1912. The decrease was due to the lower price of spelter and to the decline in recoverable spelter from 10,623 tons in 1912 to 10,088 tons in 1913. Most of the mines in the Badger-Peacock district were idle, and the district produced little ore. The Lawton district was active, several new concentrating plants were erected, and the mine output was double that of 1913. The output will probably be still greater in 1914, as several new plants will be in operation. Mine developments compared favorably with those of other years, in spite of lower prices paid for zinc concentrate, and the production exceeded the sales, so that the decline in production was not nearly as large as the figures indicate. The percentage of concentrate recovered to crude ore mined increased appreciably, indicating a lower proportion of ore from the 'sheet ground.'

MISSOURI

The value of the mine output of silver, copper, lead, and zinc in Missouri was \$29,604,890, compared with \$34,914,761, in 1912. The decrease was due mainly to the output of sphalerite concentrate being about 19,000 tons less in quantity and \$9 per ton less in value than the output in 1912. The production of sphalerite concentrate, of which all but 33 tons was derived from the Joplin region, amounted to 225,850 tons. The output of zinc carbonate and silicate in 1913 was 21,531 tons, compared with 22,172 tons in 1912. About half of this kind of zinc ore was shipped from leases of the Granby Mining & Smelting Co. at Granby, Missouri. The recoverable spelter content of the zinc concentrate (which averaged slightly lower in 1913 than in 1912), was 124,963 tons in 1913, against 136,551 tons in 1912. The total quantity of lead concentrate produced was 255,723 tons, or 1115 tons less than in 1912. The mines operating in the district of disseminated lead in southeastern Missouri reported the production of 218,949 tons of galena concentrate, averaging 67.2% lead. The Joplin region reported the sale of 35,979 tons of galena concentrate and 323 tons of lead carbonate concentrate, a slightly smaller yield of both classes of ore than in 1912. The estimated total quantity of lead, zinc, and copper ore treated in Missouri in 1913 was 12,300,600 tons, or about 1,000,000 tons less than in 1912. The decrease was due almost wholly to the lessened activity in the 'sheet ground' mines in the Joplin region. A good deal of prospecting was successful, and when prices advance many districts in the Joplin region will show an increased output. The yield of silver and copper was derived mainly from the dressing of lead concentrate from mines in southeastern Mis-

souri. [Details of the production of various districts in Missouri was published in this journal of January 10, 1913.]

OKLAHOMA

Oklahoma was the only one of the central states which showed a larger output of both lead and zinc in 1913 than in 1912. The value of the silver, lead, and zinc produced at mines was \$1,855,217, compared with \$1,101,042 in 1912. The metal content of lead concentrate increased from 3388 tons, valued at \$304,920, in 1912, to 6228 tons, valued at \$548,064, in 1913, and the recoverable spelter increased from 5769 tons, valued at \$796,122, to 11,664 tons, valued at \$1,306,368. The increased yield of lead and zinc in 1913 was entirely due to operations in the Miami field, as the mines in the Quapaw and Peoria districts reported a much smaller output and there were no shipments of sphalerite from the Arbuckle Mountain region in Murray county. The relatively small output of zinc silicate came entirely from the Peoria mines. Most of the mines in the Quapaw district were idle the greater part of 1913 and the value of their product was less than half that of 1912. Drilling operations were conducted over a wide area from the immediate vicinity of the city of Miami northeast to the Kansas line and southwest across Neosho river. This drilling resulted in the discovery of some extensive bodies of mineralized ground, the sinking of new shafts, and the erection of concentrating plants, some of which were not put in operation during 1913. The water-level has been lowered to about 320 ft., and an increasing quantity of ore was hoisted from the lower levels. The most productive mines on the Commerce Mining & Royalty Co.'s lands were the Mizpah, Turkey Flat, Cactus, Sullivan, Old Chief, Midas, Lennan, King Jack, and Lost Trail. On the Emma Gordon Mining Co.'s lease the producing mines were the Carson, Thirty Acre, Emma Gordon, Prairie, and Miami (Lennan).

WISCONSIN

The value of the mine output of lead and zinc in this state was \$2,570,464. The value of the production in 1912 was \$4,793,190, the decrease in 1913 being, therefore, \$1,222,726.

The Benton district was much the largest producer of both lead and zinc concentrates, though the yield of galena declined 256 tons and that of sphalerite 4217 tons compared with 1912. Hazel Green was the next largest producer of sphalerite, with shipments of 18,499 tons, or about 1100 tons less than in 1912. The only districts in Wisconsin which showed materially increased shipments of lead and zinc concentrates were Linden and Livingston.

[Details of the production of the various districts in Wisconsin were published in this journal of January 17, 1913.]

Average market prices used by the Survey in 1913 were as follows: silver, 60.4c. per oz.; electrolytic copper, 15.5c.; lead, 4.4c.; and spelter, 5.6c. per pound.

SUMMARY OF ALL CENTRAL STATES

| State. | Ore treated, short tons. | Silver, fine oz. | Copper, pounds. | Lead, short tons. | Zinc, short tons. | Total value. |
|------------|-----------------------------|---------------------|--------------------|----------------------|----------------------|--------------|

*Includes only ore from northwest Illinois; tonnage of ore from southern Illinois not available.

†Production from shallow mining; galena hand cobbled.

‡Tonnage not available.

Company Reports

PIONEER TIN MINING COMPANY

This Company's property is at Bradshaw's creek, Tasmania, and the report is for the year ended December 31, 1913. Tin drift sluiced was 450,600 cu. yd., yielding 327 tons of black tin. The Pioneer property averaged 1.793 lb. per yard, at a cost of 10.51c. per yard. A dividend of 60c. per share was paid.

NEW CHUQUITAMBO GOLD MINES, LIMITED

This Company operates a gold mine in the district of Cerro de Pasco, Peru. The property has been developed by open cuts and adits and is equipped with a long tramway, 40-stamp mill, and cyanide plant. During the year ended June 30, 1913, the amount of ore treated was 23,673 tons, yielding a profit of £2370. The cyanide plant has up to the present proved ineffective, and is the cause of monthly returns not being up to anticipation.

WAIHI-PAEROA GOLD EXTRACTION COMPANY

The business of this Company is to recover tailing deposited in the Ohinemuri river by the mills of various properties at and near Waihi, New Zealand, and recover the gold contained. The tube-mill plant, described in this journal of May 10, 1913, is the largest in the world, and the capacity of the regrinding and cyanide plants is 500 tons per day. During 1913 the river was very low and interfered with dredging work. Another grab dredge is to be installed. Tailing treated amounted to 140,100 tons yielding \$202,000, with a net profit of \$24,000. Since 1912 over 255,700 tons has been treated for gold worth \$385,000.

FRONTINO AND BOLIVIA (SOUTH AMERICAN) GOLD MINING COMPANY, LIMITED

This Company's property consists of gold mines known as Silencio, Cordoba, la Salada, San Joaquin, and others, having a total area of 5000 acres in the republic of Colombia. Some of the mines are being leased and others are being worked by the Company. An electric plant is at work. During the year ended June 20, 1913, the tonnage treated in the reduction works was 32,888 tons averaging \$12.30 per ton. The revenue was \$410,000 from this ore, and \$39,000 from lessees, etc. Costs, including London expenses, were \$10.48 per ton, and the profit \$80,000. Ore reserves in three mines are estimated as 41,200 tons worth from \$5 to \$18 per ton.

AMALGAMATED ZINC (DE BAVAY'S), LIMITED

This Company's business is to purchase current and old tailing from certain mining companies at Broken Hill, New South Wales, treat the product by flotation, and ship zinc concentrate for export. The annual meeting was held in Melbourne, Victoria, on March 26. During the second half of 1913 the plant treated 253,225 tons of tailing yielding 73,947 tons of zinc concentrate, averaging 49.2% zinc, 6% lead, and 8.9% silver; also, 804 tons of lead concentrate averaging 52.2% lead, 35.3 oz. silver, and 18.6% zinc. This output was 7796 tons of zinc and 24 tons of lead concentrate over that of the preceding period. The revenue was \$1,277,000; working profit, \$295,000; and adding the balance from the last period, the amount available was \$680,000, of which \$297,000 was paid in dividends.

OREGUM GOLD MINING COMPANY OF INDIA, LTD.

This is another Indian company, managed by John Taylor & Sons, of London, the property being in charge of R. H. P. Bullen. The reports for 1913 include the following information. The total number of workmen employed was 4694, of

whom 2903 natives were underground and 97 were Europeans. Development totaled 14,813 ft. In Taylor's stope of the mine good ore was opened on No. 44, 46, and 47 levels, south of the dike. In the south part of Oakley's stope rich quartz ore is being extracted on No. 51 level, the deepest in the mine. No. 42, 43, 44, and 45 levels in Bullen's stope is developing well. Ore reserves amount to 186,947 tons. The mill crushed 153,636 tons of ore, and the sand and slime plants 139,876 and 26,330 tons respectively, with a total gold production worth £360,889. All costs amounted to \$5.44 per ton. The profit was £174,832, of which £129,251 was paid in dividends. The output since 1888 is 2,402,346 tons valued at £6,639,539, and £2,214,321 in dividends.

LONELY REEF GOLD MINING COMPANY, LTD.

This Company's property is near Inyati, Rhodesia, and the report for 1913 includes the following information: Ore reserves are estimated at 172,557 tons averaging \$17.14 per ton. Recent development shows a low-grade zone at No. 10 level; but a winze below this level has been sunk from 62 ft. to 110 ft. since the beginning of the current year, and has opened better ore. The lode was strong, but unprofitable for nearly 40 ft., after which it improved to \$15.50 over 57 in. at 105 ft., and \$14 over 51 in. at 110 ft., the deepest point. It is hoped that this may indicate that the limit of the low-grade zone on No. 10 level has been reached. The mill treated 58,903 tons of ore yielding gold worth £218,520. Dividends totaling £81,302 were paid, and £53,709 spent on capital work. The balance carried forward is £13,192, against £31,214 in the previous term. Working costs were \$7.52 per ton.

GREAT BOULDER PERSEVERANCE GOLD MINING COMPANY, LIMITED

This Company's property is in the heart of the 'Golden Mile,' Kalgoorlie, Western Australia, and the report for 1913 contains the following: Development covered 8065 ft. at a cost of \$10.93 per foot. Ore reserves total 516,978 tons of positive and 321,280 tons of probable ore, averaging \$5.50 per ton. The stock of broken ore amounts to 200,178 tons. Work on the Furness and 'D' lodes has given good results. At 2050 ft., a branch of the Lake View lode, of better value than the original drift, may lead to better results at 2200 ft. The dry crushing, roasting, pan grinding, agitating, and filter-pressing plants treated 244,841 tons, yielding 59,451 oz. gold and 6865 oz. silver, worth £253,219. The recovery was 90.26% at a cost of \$2.31 per ton. Costs were: mining, \$1.70; stope filling, 1c.; treatment, \$2.31; disposal of residue, 11c.; and general expenses, 18c.; a total of \$4.31 per ton, or £220,604. After writing off development and depreciation, the net profit was £6897. The balance from 1912 was £57,747, and that for 1914 is £64,644.

NIPISSING MINES COMPANY

This Cobalt, Ontario, Company is so well known that it needs no introduction for its report for the year ended December 31, 1913. The general manager, R. B. Watson, makes the following statement on the work done: Prospecting by hydraulicking was done in 217 days, clearing an average of 3.9 ft. of overburden from 54.69 acres. The work exposed a number of stringers and some promising fissures worth further development. Diamond-drilling in six holes in the diabase area totaled 2239 ft. Results were not favorable. Underground work amounted to 13,664 ft., and 44,017 cu. yd. of stoping. Broken ore in stopes at the end of the year was 65,393 tons. Ore reserves consist of 2464 tons averaging 1897 oz. silver per ton, and 212,180 tons assaying 22.8 oz., the total silver being 9,510,014 oz. The high and low-grade mills treated 1200 and 77,240 tons of ore respectively. The refinery produced 6,530,871 oz., of which 4,844,169 oz. was from Nipissing ore. The average price received was 60.261c. per oz., and the revenue

from silver, cobalt, and nickel was \$2,920,706 net. The cost of production was \$1,096,341. Dividends amounted to \$1,800,000, and the surplus is \$1,259,061. The output to date is 32,585,418 oz. silver, yielding a net value, including cobalt, nickel, and arsenic, of \$17,569,166, of which \$11,998,297 has been paid in dividends.

BUNKER HILL & SULLIVAN MINING & CONCENTRATING COMPANY

The report of this important Idaho Company for 1913 is presented in its usual excellent form, containing 30 pages of data and three large mine plans. Operations, including the statement of the manager, Stanly A. Easton, and the accounts are best given in tabulated form:

Mine:

| | |
|--|-----------|
| Development, feet | 2,203 |
| Cost per foot | \$8.849 |
| Ore reserves (Stemwinder, Sullivan, and Bunker Hill mines, tons) | 3,842,010 |
| Ore stoped, tons | 436,060 |
| Cost per ton: | |
| Stopping | \$1.396 |
| Tramming | 0.067 |
| Hoisting (315,456 tons) | 0.059 |
| Pumping | 0.041 |
| General mine expense | 0.582 |
| Underground improvements | 0.067 |
| Total mining cost, including development | \$2.225 |

Mill:

| | |
|-------------------------------|---------|
| Time in operation, days | 355 |
| Ore concentrated, tons | 436,643 |

Cost per ton:

| | |
|---|---------|
| Crushing and conveying | \$0.070 |
| Screening | 0.025 |
| Jigging | 0.062 |
| Grinding | 0.045 |
| Concentrating | 0.067 |
| General mill expense | 0.192 |
| Improvements | 0.013 |
| Total milling cost (including north mill treating 72,392 tons of tailing) | \$0.506 |
| Concentrate produced, tons (27.6c. cost per ton)... | 59,471 |
| Average content of lead in ore, per cent. | 10.154 |
| Average content of silver in ore, ounces | 3.971 |

Recovery, per cent:

| | |
|--------------|-------|
| Lead | 80.13 |
| Silver | 70.03 |

Production:

| | |
|----------------------|------------|
| Lead, pounds | 71,860,773 |
| Silver, ounces | 1,227,076 |

Financial:

| | |
|------------------------------|-------------|
| Revenue from metals | \$3,890,139 |
| Profit from operations | 1,119,961 |
| Other revenue | 165,790 |

| | |
|--|-------------|
| Total profit | \$1,285,751 |
| Dividends paid | 817,500 |
| Balance at end of 1913, including that from 1912, and excess over book values of mine and plant... | 2,880,203 |

The result of the year's work, as to production, earnings, and new ore found, compares well with that of past years. The development of new ore on No. 13 level, 800 ft. vertically below the Kellogg (mill adit) tunnel, has been satisfactory. The continuation to this level of three important ore-shoots from No. 12 level and their great value, has been already shown. The shaft is being sunk to No. 14 level, with all conditions regular and normal. More of the old upper workings of the Tyler, Bunker Hill, Stemwinder, and Sullivan mines were thrown open to tributaries, or lessees, and as royalties from this production there was collected during 1913 the sum of \$14,256.

Research and experimental work to improve the mill work was continued throughout the year, and the economic extraction shows 1.7% higher than that reported in the last annual report.

Litigation with the Caledonia Mining Co. was settled. There is some doubt as to the action of the Stewart Mining Co., concerning the dismissal of its suit against the Bunker Hill & Sullivan company. About 94% of the shares of the Sierra Nevada Consolidated Mining Co. have been acquired.

TONOPAH BELMONT DEVELOPMENT COMPANY

From the treatment of 172,398 tons of ore, this well known Nevada Company marketed 131.19 short tons of silver and 1.31 short tons of gold, worth \$4,199,133, out of which \$1,650,000 was paid in dividends, during the financial year ended February 28, 1914. Any company report could be summed up in this way; but a great deal of interesting work is done to produce such excellent results, a resume of which is as follows:

The general superintendent, Frederick Bradshaw, reported that development covered 25,696 ft., nearly double that of any previous year. Each foot of development was equal to

PLAN OF IMPORTANT MINES AT TONOPAH.

6.71 tons of ore sent to the mill, at a cost of \$.186 per foot. A fair amount of prospecting was done on the 600, 700, and 800-ft. levels. At 900 ft., cross-cuts and raises were driven on the Belmont vein, the former to look for possible parallel veins. At 1000 ft., the Occidental vein has proved profitable for 150 ft., and the Lillie Belle vein was narrow but of good grade for 200 ft. Drifts 1042, 1048, 1049, 1055, and 1056 were driven on the Shaft vein for prospecting purposes. At 1100 ft., a cross-cut opened a branch of the Mizpah Fault vein, exposing so far 150 ft. of stoping ore. North cross-cut 7 cut the Favorite vein, the east and west drifts showing 280 ft. of ore. The west drift on the Shaft vein opened another good ore-shoot. On the 1166-ft. level, drifts have developed ore for 700 ft., and the east drift on the Belmont vein has opened a rich shoot. A good deal of work was done on No. 12 level, exposing a large low-grade vein, and 2 to 3 ft. of rich ore in the Mizpah Fault vein. Rich ore was opened in a short shoot in the Mizpah Fault vein, branch 'B'. The Belmont vein developed well. At 1400 ft., an east drift on the Belmont vein has proved ore for 400 ft. east of the Belmont shaft. Since the date of the report this vein has been cut on No. 15 level. Mining costs were \$4.699, of which stoping amounted to \$2.681 per ton of ore milled. The main shaft was sunk from 1559 to 1718 ft. A Nordberg air-compressor, and Word drill sharpener were installed. An electrically driven quintuplex pump of 100 gal. capacity per minute against a head of 1750 ft. is to be placed on No. 15 level, in addition to the present 2000-gal. machine.

The mill superintendent, A. H. Jones, reported that the 60-stamp mill treated 172,398 tons of ore yielding 44,466 oz. gold and 4,251,746 oz. silver, with an average recovery of 94.45%. An average of 54.8 stamps crushed 8.66 tons per stamp day. There was no new construction of importance. The Company's custom plant at Millers, 12 miles north, treated 18,088 tons of mixed ores, sand, and slime, averaging \$18.90 per ton, with 87.39% recovery. The profit from this mill was \$38,547.

The undivided profits of the Company at the end of February, 1914, were \$2,126,763.

Monthly Copper Production

AHMEEK COPPER MINING CO., Kearsarge, Michigan. \$1,250,000 in \$25 shares; 24,796 shares owned by Calumet & Hecla; 1500-ton mill at Hubbell; concentrate smelted by Calumet & Hecla smelter. Total in 1913, 9,100,000 pounds.

ALLOUEZ MINING CO., Allouez, Michigan. \$2,500,000 in \$25 shares; controlled by the Calumet & Hecla, which owns 43,000 shares and \$250,000 in notes of the Company; ore is milled by the Lake Milling, Smelting & Refining Co., in which the Allouez owns half. Total in 1913, 4,091,129 pounds.

ANACONDA COPPER MINING CO., Butte, Montana. \$108,312,500 in \$25 shares; controlled through Amalgamated Copper Co. which owns 3,185,240 shares by Thos. F. Cole, J. D. Ryan, and Standard Oil interests; 10,000-ton concentrator and smelter at Anaconda; 5000-ton concentrator and smelter at Great Falls, Mont.; also 70-ton electrolytic refining plant at Great Falls. Production figures include copper from all companies which ship custom ore to Anaconda smelters. Total in 1913, 270,301,644 lb. copper, 64,898 oz. gold, and 10,321,296 oz. silver.

Decisions Relating to Mining

OIL LEASE—WRITTEN AND PRINTED PROVISIONS

Where an oil lease is drawn on a printed form, provisions written in will prevail over conflicting provisions in the printed part.

Amsdell v. Cherry Gas & Oil Co. (New York) 145 New York Supplement, 825. December, 1913.

OIL AND GAS LEASE—RECOVERY OF RENTALS PAID

Where lessees attempted to recover rentals paid the lessor, under an oil and gas lease, on the ground that the lessor's title was imperfect, but were unable to show any obstructions to their taking possession or attempted eviction from the land, they have failed to show a breach of the lessor's covenant for quiet enjoyment and recovery will be denied.

Gaffney v. Stowers (West Virginia) 80 Southeastern, 581. December 16, 1913.

MINING PARTNERSHIP—CONTRIBUTION

Under a partnership agreement, one partner conducted operations on a mining claim and incurred certain indebtedness to the payment of which the other partner contributed his share. At a later date after outstanding indebtedness had been discharged he notified the working partner that he would not be responsible for any further obligations. Notwithstanding such notice the working partner continued operations and later sought to hold his partner to account in an action for his share of the expense. Held, that the agreement terminated upon the notice and defendant could not be so held.

Goldsmith v. Murray (Montana) 138 Pacific, 187. December 16, 1913.

OIL LEASE—ACCOUNTING DENIED

A common lessee of two adjoining tracts drilled an oil well near the boundary line on what he supposed was tract A, and by a large sign posted near, as was the custom, announced that he was drilling the well under lease from the owner of Tract A. After the expiration of ten years, during which time no objection was offered, the owner of tract B caused a survey to be made which determined that the well was on tract B. Held, that the lessee was not estopped from denying the title of the owner of B, as he had never claimed to operate under that lease, and that the owner of B was debarred by limitations from claiming an accounting from the lessee.

Lockwood v. Carter Oil Co. (West Virginia) 80 Southeastern, 814. February 12, 1914.

OIL LEASE—RECISSION DENIED

An oil lease contained the following provision: "It is expressly understood that the second party (lessee) reserves the right to abandon said premises whenever it desires to cease operations, and to remove all property placed thereon by it, at discretion." Held, that such provision destroyed the obligation placed upon the lessee, and hence the contract was without consideration when entered into. However, if the lessee proceeded to comply with the provisions of the lease, and actually drilled wells and developed the land to a certain extent, the lessor could not, merely because of a difference of opinion between it and the lessee as to further development requirements, cancel the lease on the grounds that it was without consideration, unless the lessee is restored to his *status quo* at the time the contract was made.

Caddo Oil & Mining Co. v. Producers Oil Co. (Louisiana) 64 Southern, 685. March 16, 1914.

Industrial Progress

The Elspass Mill

Chilean mills of various designs have found favor with many millmen for crushing coarse ore, up to 2-in. size, and for regrounding pulp for further concentration and treatment. In the older type of Chilean mills, the delivery of the ground product is dependent entirely upon the slushing of the pulp by the rollers against the screen. As this action brings only a small portion at any instant against the screen, the balance is retained until a greater portion is reduced

SECTION THROUGH MILL.

to slime, which may or may not be desired. The 'New Principle' Chilean mill, as designed by the Elspass Engineering & Mining Machinery Co., of Denver, Colorado, consists of a heavy, rigid, revolving bed, the bottom of which carries a heavy steel die ring, and upon this ring rest three massive stationary rolls, 6000 lb. each. Instead of these being dragged around upon the die ring by a central moving journal, as in the older style of mills, the bed below carrying the die ring is made to revolve beneath the rollers, which remain in a stationary position, and merely revolve upon their respective journals as the die ring passes beneath. The wearing surfaces are made of hammer-forged steel. The screen embraces the outer circumference of the revolving bed, and travels with it. There is at all times 36 ft. of screen surface in action. Ore up to 1-in. size gives efficient crushing results, and on quartz the capacity of a mill is from 50 to 75 tons per 24 hours, through a 30-mesh screen. The machine is said to be suitable for preparing zinc and lead ores for concentration, makes little slime, produces an even product, and extracts a high percentage of gold by amalgamation in the mill. A cross-section of the mill, furnished by the manufacturer, appears above.

THE SMITH-BOOTH-USHER Co. reports the election of the following officers: H. P. Usher, president and managing director; J. R. Hoffman, vice president; F. P. Duncklee, treasurer; J. A. Nickell, secretary; E. H. Breidenbach, general manager of sales.

THE GENERAL CHEMICAL Co. has issued a general price list of the chemicals made at the Baker & Adamson Works, which includes valuable tables showing formulas, composition, solubility, and percentage composition of the various chemicals.

R. C. COLE has joined the staff of the pneumatic tool department of the Ingersoll-Rand Co. and has been stationed at the Chicago office.

EDITORIAL

COL. ENOS A. WALL, of Salt Lake City, has brought suit at Wilmington, Delaware, for the dissolution of the Consolidated Coppermines Company, and has asked for the appointment of a receiver. This, the latest of the Wall suits, which have come to be regarded lightly in certain localities, makes as defendants a long list of some of the most well known names connected with the copper industry. The opinion of one of the officials of the Company is that the suit was founded on misrepresentation of facts, and the counsel states that it is without merit.

School of Mines Semi-Centennial

Great schools are not collections of buildings or of books, but of great men. The Columbia School of Mines, which is celebrating in New York this week the completion of fifty years of successful work, celebrates not its growth from dark and cramped quarters in the basement of an unused building to the possession of spacious buildings and elaborate equipment, but commemorates rather the achievements of a group of great teachers and rejoices in the work of its graduates. In such teachers as Egleston, Newberry, Vinton, Chandler, Rood, Peck, and Van Arninge, the young school had the first essentials of success, and Columbia University has grown from a minor position to the leading place among the universities of the United States, and its School of Mines has not only shared in that growth, but contributed materially toward it.

To name the graduates of the School of Mines at Columbia who have risen to honor in the mining profession would require more space than is possible to accord. Nevertheless, a few must be mentioned to indicate how the history of the school is interwoven with the development of mining and metallurgy in America. In the first class, 1867, were Messrs. John A. Church and H. B. Cornwall; 1868 included F. A. Schermerhorn, W. H. Van Arsdale, and A. H. Chester. Messrs. H. S. Munroe, W. P. Jenney, and R. D. Irving were of the class of 1869, and Elwyn Waller and T. F. Van Wagenen graduates in 1870. S. A. Goldschmidt and P. de P. Ricketts of 1871, and T. O'C. Sloan in 1872 lead up to the class of 1874, in which were Messrs. W. DeL. Benedict, A. R. Ledoux, E. E. Olcott, and F. B. Rhodes. Messrs. M. W. Iles, W. S. Noyes, C. M.

Rolker, and M. C. Ihlseng were of the class of 1875; T. S. Austin, G. R. Cornwall, F. R. Hutton, and N. W. Lord of the class of 1876; Carl Barus, S. A. Reed, and Arthur Thacher, 1877; and W. B. Devereux, B. B. Lawrence, and Bailey Willis, 1878. George C. Stone of 1879, Herman Garlichs, W. B. Kunhardt, and Frank Klepetko of 1880, and V. M. Braschi, A. L. Colby, and H. Van F. Furman of 1881 are only a few of those whose names deserve mention. John B. Porter and E. L. Young, 1882; J. P. Channing, Robert Peele, and A. L. Walker, 1883; J. F. Kemp and William Newbrough were of 1884; while A. S. Dwight, E. N. Engelhardt, George B. Lee, F. J. H. Merrill, Richard Moldenke, R. Van A. Norris, W. E. Sanders, and Joseph Struthers were of the banner class of 1885. J. H. Janeway and E. L. Newhouse of 1886, W. H. Aldridge, Jennings S. Cox, and F. M. Stanton of 1887, Edwin Gould and C. H. Smyth of 1888; R. Gilman Brown, F. W. Denton, Karl Eilers, and F. M. Smith of 1889 are but a few of the men of those years who have left an indelible mark in their profession. To name the prominent graduates of the years since 1890 would almost sound like calling the roll of the active younger men of the mining profession. The School of Mines may well be proud of her sons. To them and their school we wish Godspeed, continued success and honor, with a faithful adherence to the noblest ideals of an honorable profession.

Potash Production and Borax Prices

In connection with the impending advent of the American Trona Corporation into the market for potash, there is more than a hint of trouble for borax producers. It will be recalled that Borax Consolidated Ltd. when formed in 1899, acquired the physical properties of the Pacific Coast Borax Company at the same time that properties in Chile, leases in Turkey, and other sources of raw material around the world, were purchased. At the same time the Pacific Coast Borax Company of California was formed by Mr. F. M. Smith and his associates. This new concern received 364,710 of the deferred ordinary shares of Borax Consolidated in payment for the properties transferred, and, having purchased 135,290 additional shares, now holds 500,000 of the 900,000 shares which have voting control of Borax Consolidated. The Pacific Coast Borax Company of California is dominated by Mr. Smith. He, with Messrs. L. H. de Friese, J. Gerstley, and R. C. Baker, are managing directors of the Borax 'trust'. Borax Consolidated has prospered. The net profits have increased steadily and for the year that ended September 30 last were nearly £362,000. There is an amazing tangle of deferred and preferred and ordinary shares, but after deducting for income tax, depreciation, sinking fund, general reserve, investment reserve, and other minor items, the following payments were made: debenture interest, £74,164; preferred dividend, £44,000; preferred ordinary dividend, £27,000; deferred

ordinary dividend, £135,000; carried forward, £45,397. The rate of payment on the deferred ordinary dividend in the last four years has been at 12½, 13¾, 13¾, and 15 per cent. The shares have a par value of £1 and have naturally sold at a premium. Mr. Smith, having become involved in real estate speculations at Oakland, California, and in railway and traction ventures that were not altogether profitable, placed his interests in the hands of trustees some months ago as we noted at the time. Some of his properties already have been sold. So far his Borax shares have not changed hands though there have been negotiations with several parties and various rumors of sale. It is to be noted that their transfer, or even the sale of a part of them, might mean a change in control of Borax Consolidated. Naturally the matter has brought up the question of the value of the shares. So far they have been sold mainly on the basis of the dividend record, though the question whether the richer parts of the colemanite deposits were not being exhausted unduly, has been occasionally brought up. There is no fear as to the total amount of borax available but merely a question whether future costs will not be higher. Another danger to the Company is in connection with the Tonopah & Tidewater railroad. This line was built to provide transportation from the mines to the Santa Fe railroad and in the flush of enthusiasm over southern Nevada, following the discovery of Goldfield, it was extended until now 170 miles of line is operated. Unfortunately the railway does not pay. While the yearly deficit has not been large there is no great encouragement to believe that it can be permanently decreased. The country traversed is desert and there seems little possibility of building up a permanent traffic. The main business at present is with the mines of the Borax company, and if for any reason these should be closed, there would be little left. It does not seem to be generally appreciated that the bonds of this road are guaranteed both as to principal and interest by Borax Consolidated Ltd. There is £500,000 in 4½ per cent bonds issued in 1905 and £175,000 in 5 per cent issued in 1907 out of £250,000 authorized at this time. If for any reason Borax Consolidated should find it necessary to transfer its main activities to another field, there would be here a heavy loss to face.

Competition in borax production has so far been unimportant though there are independent producers. There is now, however, the threat of competition that may put another face on matters. The American Trona Corporation, as already noted in our news columns, has completed a railroad to its works and is rapidly building a plant designed to manufacture soda ash, borax, and potassium chloride, from the brine of Scaries lake. Interesting details of this enterprise were printed in the *Mining and Scientific Press*, June 14, 1913, and since then rapid progress in construction has been made. The various salts have already been manufactured on a working scale and before January it is expected that regular production will be under way.

The plant now being built is small though each piece of machinery is of standard size. It is designed with a view to experimental work directed to obtaining the maximum efficiency in the larger works to follow. The process used was worked out by Mr. John W. Hornsey and after being tested in the laboratory was applied on a larger scale in the old works of the Pacific Coast Borax Company, now under lease to the Trona company. It consists, essentially, of evaporation and fractional precipitation of the soda ash, salt, sodium sulphate, borax, and potassium chloride. The material is derived from brine pumped from the interstices of a crystal body covering several square miles and extending to 60 or 70 feet in depth. The quantity available is undoubtedly adequate and the process to be used has been tested sufficiently to assure its success and economy, though exact statement of costs must wait actual operation on a large scale. The plant will be built in four units and when all are working is to produce daily 500 tons of soda ash, 490 potassium chloride, 225 borax, 1500 salt, and 590 sulphate of soda. There is no adequate market available for the salt and sulphate so the Trona Corporation must derive its revenue from the sale of the other salts. The amount of potassium chloride contemplated is less than that at present annually imported into the United States, and would in any event be absorbed by the normal growth of the American market in five years. As the raw material is obtained by pumping as against mining under peculiar and expensive conditions in Germany, little fear is felt as to the market for this material. The amount of soda ash to be produced is equivalent to about 5 per cent of the present world's consumption and as freight to deep water at San Pedro will be not more than \$1.50 per ton, it is felt that a ready market, probably in the Orient, will be found for all that it is now proposed to manufacture. The critical factor is the borax. It is evidently a matter of book-keeping so far as the Trona Corporation is concerned, as to what the borax costs. It must be taken out of the brine in order to bring down the potassium chloride. It can therefore be sold for anything over freight and handling charges better than thrown on the dump as the salt and sulphate must be at present. The amount to be made is about equal to the present world's consumption, and if it be marketed, borax mines must close elsewhere, at least temporarily.

Borax Consolidated has succeeded in materially expanding the market for its products. The United States output has increased from 5959 tons in 1895 to about 43,000 tons in 1913. Since 1870 the price has fallen from 35 to 4 cents per pound. Probably a still lower price would increase the use of borax, especially in the dyeing, enameling, and glass trades, but there is no evidence that the world's markets will absorb double the present output in even a few years, without a very material decrease in price. It is one of the curious chances of time that the Trona company is now operating in works originally built by Searles, and

which were one of the pioneer plants of the Pacific Coast Borax Company, whose prosperity is threatened by the new development. The San Bernardino Borax Company, a subsidiary of the Pacific Coast, owns the land and the works. The land covers the mud flats but does not extend into the crystal body originally located by the California Trona Company with a view to manufacture of soda. This Company leased the old borax works and to guard against any possible competition it was stipulated that during the life of the lease, which has still four years to run, the Borax company should have an option to purchase at 1 cent per pound all borax that might be produced by the Trona company, and the latter should have a reciprocal option at 1/5 cent per pound on all soda made by the Borax company. At that time potash was known but its value was not appreciated. The California Trona Company borrowed money from the Foreign Mines Development Company and for various reasons came to grief. The Consolidated Gold Fields people, who were backing the Foreign Mines Development Company, bought control of the Trona company and eventually organized the American Trona Corporation, to build and operate the works. The value of the potassium was discovered by one of the engineers of F. S. Pearson who at one time held an option from the California Trona Company, and the discovery was exploited by the United States Geological Survey. When first Trona company began work there was no intention of producing borax but with the development of the process for making potash salts a new situation arose. Borax Consolidated still holds the option on the borax output of the plant but can not take the amount offered without interfering with its regular business. On the other hand, Borax Consolidated undoubtedly has a firm hold on the market and a newcomer will have to fight to get in. The big customers, however, are those who would buy on specifications and price; and, within rather wide limits, the latter is unimportant to the Trona Corporation. The situation is one of much interest. The Borax company did have one club over the Trona Corporation until recently in that it owned the only suitable patented land for the erection of a plant. Following the announcement of the Geological Survey, of the presence of potash in the brine, all the lands around the lake were withdrawn from entry in 1912. This does not affect the locations on mineral land, including the crystal body, which the Trona company owns and which were made prior to the President's proclamation; but it did prevent acquirement of land for the necessary mill and townsite. After proper showing of the non-mineral character of the land and a long and annoying delay, a sufficient area was recently released and has been purchased by the Trona Corporation. The latter accordingly no longer has to have the Borax property, though it would be convenient to own the land, and interested observers anticipate that in the end some amicable adjustment will be made between the two Companies.

DAVY MILL OF THE AMERICAN ZINC COMPANY.

Mining and Milling at the American Zinc Property, Joplin

By E. H. LESLIE

The southwest Missouri zinc and lead mines are divided into three main classes of which the 'sheet ground' properties are by far the most important and have produced the greater part of the zinc concentrate of the district. The 'sheet ground' lies at a variable depth of from 100 to 250 ft. below the surface and is covered with a limestone formation which, in the conduct of mining operations, is supported by pillars of from 20 to 40 ft. in diameter. Another class of deposits is known as the hard disseminated orebodies which are similar and sometimes classed with the 'sheet ground' deposits. The mining methods are similar with the exception that in hard disseminated ground less ore is left under ground as pillars and rooms are often left which are from 30 to 40 ft. wide, 50 to 100 ft. long, and 20 to 100 ft. high. The other class of deposit is locally known as the 'soft ground' deposit and in mining this type of ground timber sets, stulls, and spiling, with lagging is usually necessary.

The property of the American Zinc, Lead & Smelting Co., which is one of the largest producers of concentrate in this district, belongs to the 'sheet ground' class. The mining and milling operations as conducted here represent the most efficient and modern practice in the working of this type of orebody and as representative of zinc mining and modern milling practice in the Joplin district, a brief summary may be of interest.

The deposit was opened by vertical shafts and mining operations commenced as soon as the orebody was reached. In the beginning of mining operations a slice 7 ft. thick is taken from the top of the deposit,

adjacent to the shaft and when 18 or 20 ft. of bench has been uncovered, long lifters or stope holes are drilled and the bottoms are chambered and then heavily loaded and fired, the amount of dynamite used depending upon the depth of the stope holes and burden. Forty per cent dynamite is the usual grade used in mining operations. Drilling is done with the 3¼-in. Ingersoll piston drill which is handled by two men and will break about 46 tons per shift at this particular property. The machines are operated by air at 90-lb. pressure. The 'one-man' drill has not as yet found a place in Joplin mines due, as contended by the operators, to the fact that it has not sufficient 'pull back' for drilling fissured holes. In stoping operations, pillars are usually left at intervals of from 30 to 50 ft. depending upon the nature of the ground. 'Slicing' is employed where the thickness of the orebody permits and underhand stoping is the regular procedure. The pillars vary from 20 to 40 ft. diameter. At this property the tonnage broken per man, including the entire force, both surface and underground, is 5.7 tons and the tonnage broken per man for the entire underground force is 7.41 tons. This method of breaking ground is most economical, the average mining cost being 35c. per ton which is cheap when it is considered that the ground is hard and difficult to drill.

The broken ore is loaded into large buckets of from 800 to 1200 lb. capacity which are placed on small flat cars and trammed by hand out of the stopes to the main haulageway. Here trains are made up of from 15 to 25 cars and hauled to the shaft by gasoline locomotives. Three engines are used for this purpose

which were made by the Milwaukee Locomotive Company. This method of handling ore underground has proved most efficient and is a decided improvement over the time honored mule and 'mule skinner'. In shoveling the regular 'D' handle No. 2 scoup shovel is used and many shovelers will load as many as 25 tons per 8-hr. shift. The loading is done on contract at prices ranging from 6 to 8c. per bucket according to the size of the bucket.

The buckets are hoisted to the surface with small geared hoists mounted in the top of the head-frame, a particular type of which has been developed in the Joplin district. A side elevation of the new head-frame at the American property which is one of the most modern in the district is shown in the accompanying drawing (Fig. 1). The head-frame and ore-bins, which

FIG. 1. SIDE ELEVATION, SHOWING METHOD OF FRAMING.

are a part of the structure, are supported on heavy concrete foundations and are of heavy timber as indicated in the drawing. The hoistman dumps the buckets directly into the mill bins. There are no guides in the shaft and a $\frac{5}{8}$ -in. non-spinning steel cable is used for hoisting. Electric hoists are replacing the steam equipment throughout the district and one hoist will frequently raise as many as six hundred 1200-lb. buckets in an 8-hr. shift, besides raising and lowering the men.

No signals are used for hoisting ore, as the hoistman knows from experience when the 'hooker' at the bottom of the shaft has detached the empty bucket and hooked on the load. Two electric hoists, both mounted in the same head frame which is shown in the drawing and halftone, are employed at the Davy No. 3 shaft, Fig. 2. Each hoist is operated by a 75-hp. West-

FIG. 2. HEAD-FRAME AND ORE-BINS.

inghouse motor and the combined hoists have a daily capacity of about 1200 tons.

The American mine is equipped with an underground machine shop for making minor repairs on the drills, cars, and gasoline locomotives. Also there is a forge and Leyner drill sharpening machine. Ventilation for the forge is secured by a churn-drill hole which serves as a stack to the surface.

Milling Operations

Milling operations may be characterized as simple, cheap, and efficient. In the 1200-ton mill at this property, a general view of which is shown in Fig. 3, the ore is drawn from the hoppers into two 12 by 18 in. Blake crushers and the crushed ore lifted by bucket elevators to two trommel screens. The undersize from these screens which is through $\frac{1}{2}$ -in. goes directly to two 'rougher' jigs while the oversize is reground in four sets of 36-in. rolls, two others being held in reserve. These rolls discharge into the boot of the bucket elevators previously mentioned, and the reground material is returned to the trommels.

The two 'rougher' jigs are made with six compart-

FIG. 4 AND 5. EXTERIOR AND INTERIOR VIEW OF SLIME PLANT.

ments each and produce a middling product, which is reground in 30-in. rolls, and a rough concentrate. The tailing is lifted by means of bucket elevators to the stackers which removes it to the tailing piles. The concentrate from the rougher jigs is raised by a bucket elevator and discharged through a launder to the cleaner or finishing jig. The zinc concentrate and lead concentrate are taken from the first two and last two compartments of the cleaner jig to the concentrate bins. The middling product which consists of a mixture of sphalerite and galena is returned to the boot of the concentrate elevator where it joins the concentrate from the rougher jigs and again passes through the cleaner jig.

The middling, or what is locally known as the 'chats', from the rougher jig is lifted in the 'chat' elevator and discharged into a 3-mm. trommel. The oversize from this trommel is re-crushed in a pair of 30-in. 'chat' rolls and returned by the elevator to the trommel. The undersize from the trommel goes to a cone classifier, the overflow of which is laundered to settling tanks in the 'sludge' mill while the underflow is returned to the elevators and rougher jigs.

The fine sand from the rougher jigs tailing is separated by a hydraulic classifier on the end of the jig through which the tailing flows and is sent to the table room. The classifier as used on the end of the rougher jig, is a local device, which has been found most effective in the recovery of the fine sands in which most of the losses formerly occurred. The tailing in passing from the jig flows over a series of three classifier boxes. These boxes are wedge shaped with a long pipe and water jets in the bottom. The fine material which is held in suspension by the rising current is thus separated and flows through launders to the table room. From the rougher jigs an immense amount of barren rock is quickly eliminated from the mill. Power for the mill is furnished by a 150-hp. General Electric motor. The tailing from the cleaner jig locally called the 'sand' is laundered to settling tanks and a drag classifier.

Not a great many years ago the concentration of Joplin ores was done entirely by jigs and a 'rougher'

and 'finishing' jig, with the accessory equipment, constituted the standard practice. The advent of tables marked a new era in the milling practice and the combination of jigs and tables with a more careful classification has been generally adapted throughout the district. The zinc and lead concentrates from the finishing jig have been augmented by the concentrates from the 'sludge' or sand plant, and at this particular property a slime plant has been profitably added and a still further saving affected. The material which passes from the jig room to the 'sludge' or table room consists, as stated, of the sand which is removed from the tailing of the rougher jigs, the fine material from the classified reground middling product of the rougher jigs, and the tailing product of the finishing jig. All of this material is conducted by launders to the settling tanks and drag classifier where the slime is separated for the slime-plant and the sand for the 'sludge' room concentration.

Sludge Room

The sand is raised in a bucket elevator and discharged into a cone classifier which marks the initial classification in the 'sludge' room or sand concentration. The overflow of the classifier is returned to the settling tanks while the underflow goes to a 1½-mm. trommel. The oversize from this trommel is returned to the 'chat' rolls in the jig room while the undersize goes to a system of classifiers which feed the first set of 'sludge' tables. Wilfley and Arbutnot tables are used for this purpose. The lead and zinc concentrates from these tables goes to the concentrate bins. The overflow from the first set of classifiers which feed the first system of tables is re-classified in hydraulic classifiers, and treated on a second set of tables. The slime from this second classification goes to the settling tanks and slime plant. The lead and zinc concentrates from these tables goes to the concentrate bins while the middling is returned by bucket elevator to a 1½-mm. trommel. The oversize from the trommels is returned to the 'chat' rolls in the jig room while the undersize is again classified in a cone classifier, the overflow going

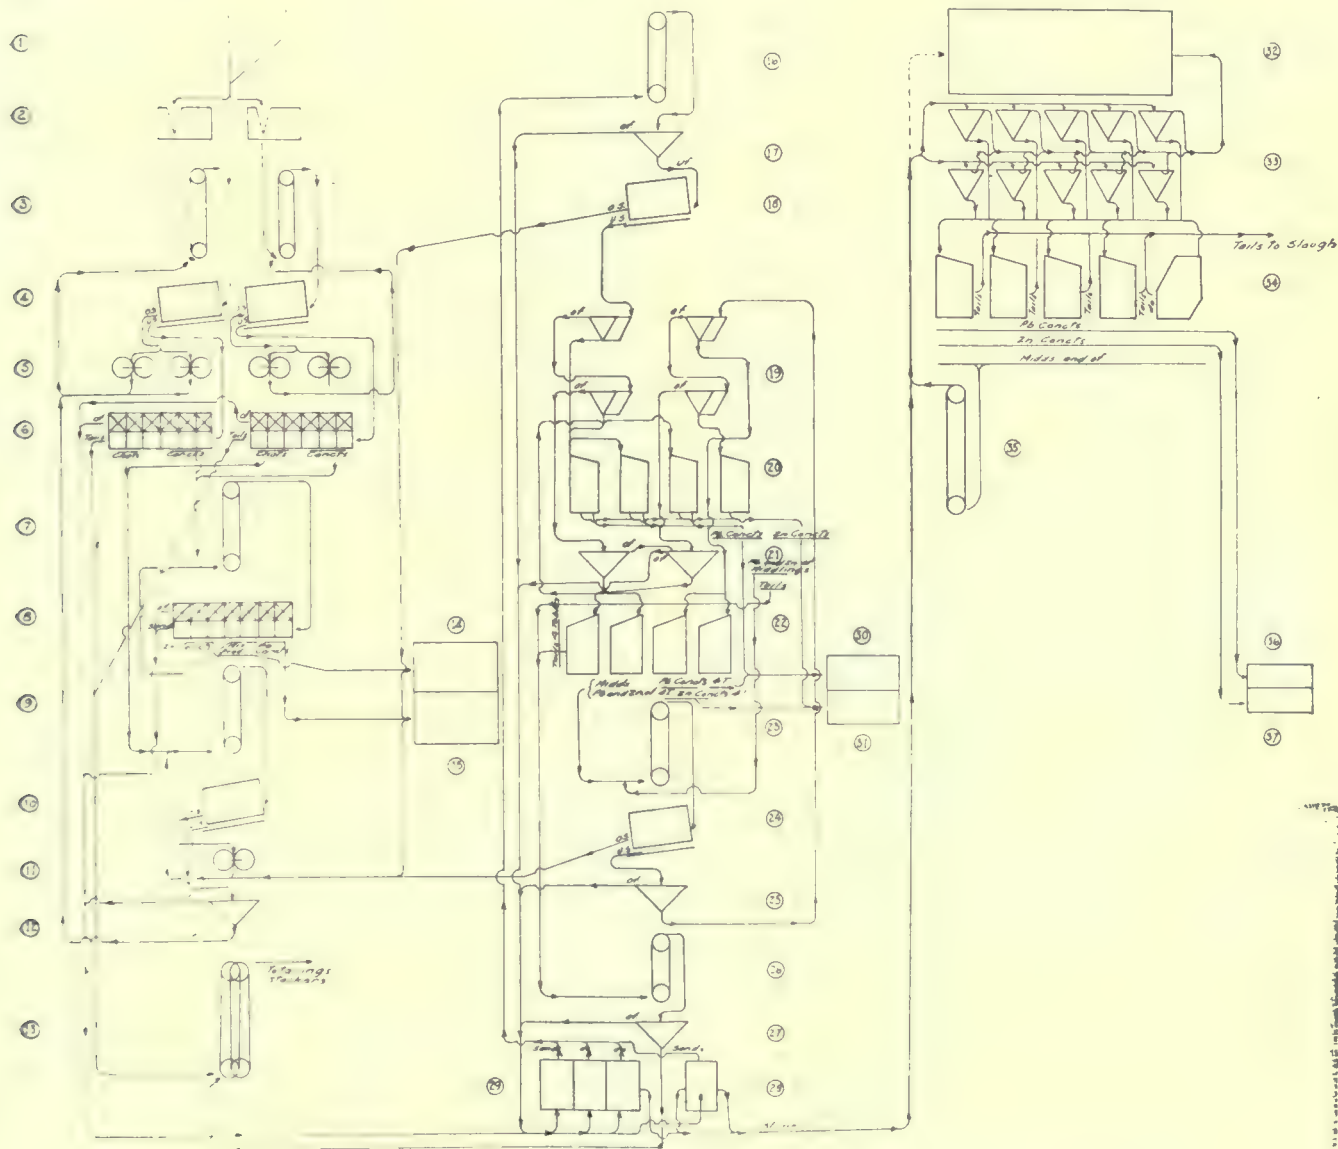

to the settling tanks and slime plant, while the underflow is returned to the first set of classifiers and tables. The system of classification appears rather complicated from a record of flow through the sand plant, but reference to the flow-sheet, herewith presented, shows the system of classification to be by no means complicated. The method adopted amounts to the separation of three products, a coarse and fine sand which are treated on two sets of tables and the slime which is passed to the settling tanks or drag classifier and from there to the slime plant.

The tailing from both sets of tables is raised in

a bucket tailing elevator and classified in a cone classifier. The overflow from the classifier goes to the settling tanks while the underflow is sent to the tailing elevators and thence to the tailing piles.

Slime Plant

The slime-plant, of which an exterior and interior view are shown in Fig. 4 and 5, is a feature of the mill, being at present the only one in the district, and owes its existence to the recent manager, J. N. Houser. The performance of the plant during the past year in which it has been in operation has proved this depart-

ment to be a valuable addition to the existing milling practice in Joplin district where a sufficient amount of slime is produced to warrant such an installation.

The slime as formerly removed from the sludge room went directly to the pond. The slime now passes to a system of ten cone classifiers which will be seen in the halftone to the left of the slime-plant. The overflow from these classifiers which contains but a very small per cent of solids, the cones acting as a dewatering device rather than classifiers, goes to the pond while the underflow is treated on five slime tables, four of which are James tables and one a Wilfley. Lead and zinc concentrate are obtained from these tables and the middling is elevated and returned to the classifiers. The tailing is laundered to the slough. The material treated in the slime plant is finer than 200 mesh and carries about 5½% zinc. The tailing contains about 1½% zinc. The total mill recovery is between 68 and 69%, and the average cost about 18c. per ton.

The method of mill tailing disposal is by bucket elevators and a launder distribution system. This method

FIG. 6. METHOD OF TAILING DISPOSAL.

is used throughout the district, the topography being almost universally level with no depressions which will permit of a gravity disposal. As the tailing piles increase in size and height a limit is finally reached and it becomes necessary to re-elevate the tailing to permit of a higher pile and broader distribution. At this property it has been found necessary to elevate the tailing three times as shown in Fig. 6. The elevation and disposal of tailing at this plant is effected at a cost of 2¾c. per ton.

The boiler plant consists of eight 150-hp. boilers, which are fitted for burning gas, coal, or oil. The Hammel oil burning system is used. As a result of the fuel equipment, a shortage in the gas supply occasions but a short delay in putting the oil system into operation. The oil storage is sufficient to run the plant through any ordinary gas failure. In the event of a shortage of both gas and oil, coal is fired under the boilers. The boiler plant supplies steam for three compressors, a 3000-ft. piston inlet Ingersoll-Rand cross compound, a 2000-ft. Laidlaw-Dunn-Gordon compound, and a 2000-ft. Rand compressor. All compressors run condensing. Electricity is used for all power pur-

poses, excepting the compressors, and is supplied by the Empire District Electric Company.

The machine shop equipment is elaborate for a property of this size and in addition to handling all of the repair work about the mine and mill, manufactures elevator buckets and machine spares for this and other properties of the Company. The equipment includes two lathes, shaper, planer, radial drill press, two pipe machines, power hammer, plate bending rolls for trommel screens, three power saws, and oxy-acetylene welding outfit. The machinery is driven by a 40-hp. General Electric motor. The store room contains a \$40,000 stock of all kinds of supplies for mine and mill use.

While the methods herein described of both mining and milling will undoubtedly appear as rather primitive to miners and millmen in other parts of the world who are accustomed to the more elaborate and costly equipment, nevertheless the results which are being obtained at total cost of mining, milling, depreciation, amortization and general expenses of less than a dollar per ton is ample evidence that the Joplin practice is most efficient and well adapted to the local conditions.

The work done in producing a given deformation of any body, within the elastic limit of the substance, varies as the volume of the body deformed, according to Arthur F. Taggart in the *Bulletin* of the American Institute of Mining Engineers. For a highly elastic substance this principle may be extended beyond the elastic limit, by the assumption that the force-deformation curve beyond the elastic limit is closely represented by a continuation of the straight line, which represents the behavior of the body within the elastic limit. For rock, which is almost perfectly elastic, this assumption is correct within the limits of experimental error. The work of crushing rock is proportional to the volumes of the particles crushed, and to the volumes of the resulting particles. Attempts to prove the work of crushing proportional to the reduction in diameter err in one of the following ways: (1) by neglecting the distance quantity in the work formula; (2) by assuming that particles in a crushing machine are acted upon in such a way as to produce simple shearing stresses; (3) by assuming that the force exerted is a constant; and (4) by confusing force and work. The difference in the results obtained according to the two assumptions is small throughout a considerable range of sizes. The difference is marked in the fine sizes, where the greatest amount of power is wasted.

Wages paid to white employees of mining companies in the Union of South Africa in 1913 totaled £9,913,490, of which the Transvaal was responsible for £8,551,921; Cape Colony, £868,982; Orange Free State, £337,081; and Natal, £155,506. Native, Asiatic, and other colored peoples were paid £8,027,541, the Transvaal accounting for £6,595,657. Total mine employees in the Union in February, 1914, were 28,750 whites and 243,531 natives, against 32,159 and 302,337 respectively in March, 1913.

A New Safety Detonator at Cornwall

By EDWARD BROWNING

Bench blasting by means of deep well drill-holes has come into general use in nearly all large open-cut mining and quarrying operations because of the greater economy found in breaking down with a primary blast masses of material, which saves the immense amount of labor formally used in bench cleaning and which gives assurance that plenty of material is on hand prepared for the shovel and for other reasons.

Always the great trouble experienced in blasting is

Probably in all large shots the more holes that are fired at one time and the deeper they are, the more the efficiency that can be procured, due to one hole helping out another, and because there are relatively less end holes. Now it is a well proved fact that the powder in a hole gives best results around the exploder. This can be seen at any time by examining the face of a bank after a shot. The powder farthest away from the exploder has decidedly less disrupting

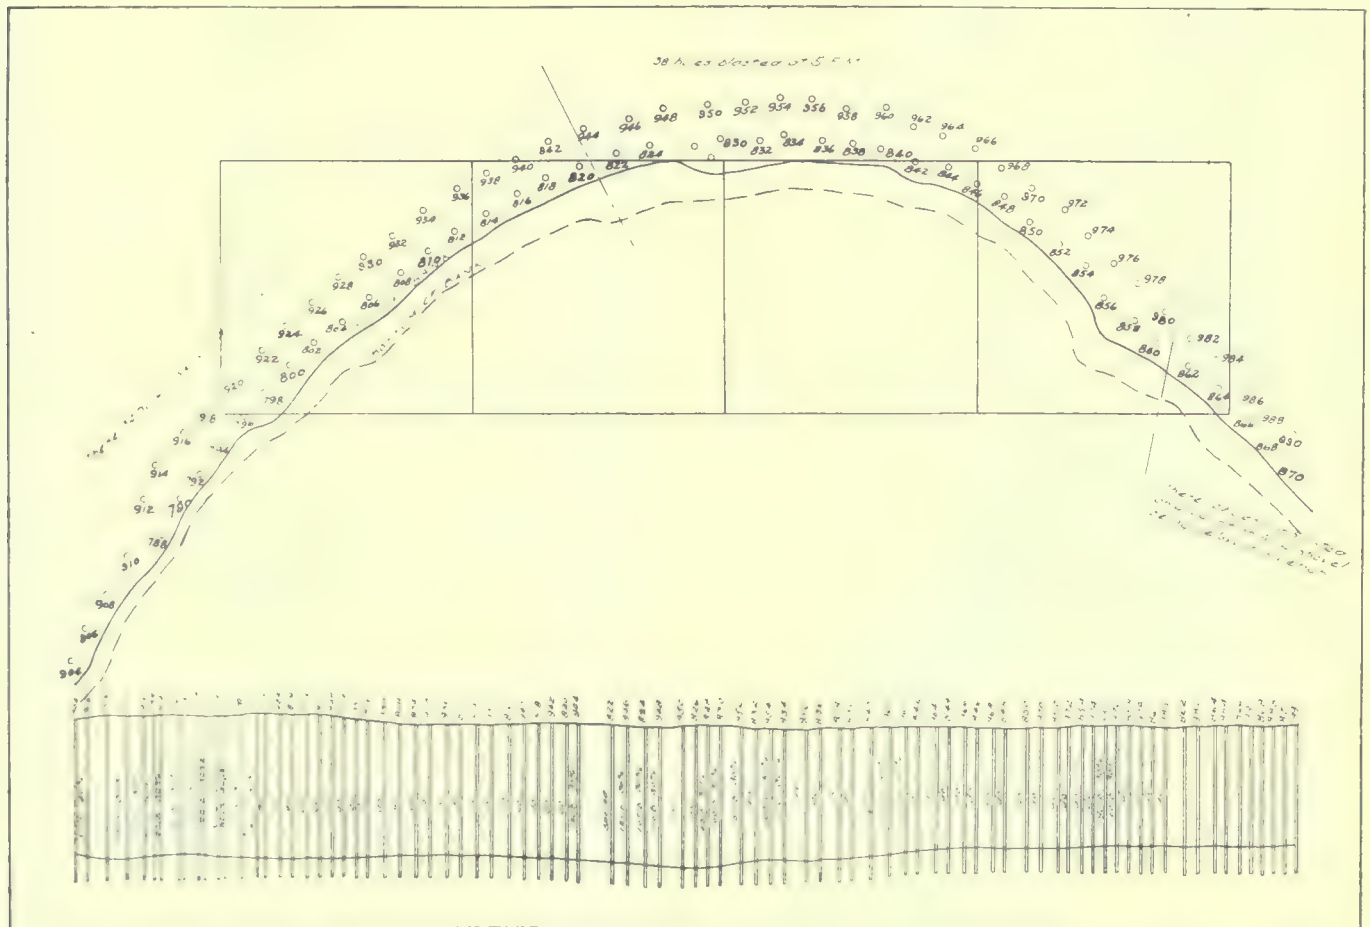

DIAGRAM SHOWING ARRANGEMENT OF HOLES AND AMOUNT OF EXPLOSIVE USED IN BENCH BLASTING AT CORNWALL.

imperfect detonation of all the holes. The charge of powder or dynamite is necessarily large on account of the amount of burden to be moved. Unless a live wire is used to set off the blast, comparatively few holes can be shot at one time, as the ordinary blasting machine is only capable of shooting a few of the long exploders, with any certainty; also by either of these methods there is always the danger of a short circuit spoiling some or all of the holes and there is the added danger of the wires being charged accidentally by lightning. The up-keep of the live-wire circuit and the leader wire is also considerable

power. The usual 4 by 8-in. stick of dynamite will fill about 1 ft. of hole ($5\frac{5}{8}$ in.) for every 15 lb. if uncut, or 33 lb. can be tamped in a hole if the dynamite is taken out of the paper. This means that if a hole is not chambered a couple of hundred pounds will fill several feet and in order to get good efficiency, two exploders are used, one near the top of the charge and one near the bottom. This insures greater safety in case one exploder is defective or the wire is broken. Also it increases the danger in loading a charge and increases the number of detonators to be exploded. In very deep holes it would at times pay to load the dynamite in

several separate charges in order to break up the rock better, but the number of wires to be handled in this case is almost prohibitive. A perfect exploder would be one that would be safe and easy to handle, that would be waterproof, would explode a charge of powder throughout its entire length, and in any number of places instantaneously.

Very recently a large powder concern brought to our notice a new exploder called 'cordeau' which answers all of the above requirements. It consists of a lead tube 5 or 6 mm. in diameter, filled with a safety explosive. This tube comes wound on reels or spools, in convenient lengths for handling. The operation of loading a hole is very simple. First the hole is pumped out if possible, then a stick of powder is tied to one end of the exploder tube and lowered down the hole. The object of the powder on the end is to give weight to the tube to facilitate lowering and to keep it taut. After the tube is all the way down, the hole is charged in the usual manner, no special precaution above the ordinary being necessary, and tamped up. After the hole is finished the cordeau is broken off, leaving about 1 ft. extending above the top and the next holes loaded and so on until all are finished.

After loading the holes the ends of the cordeau sticking out are split with a knife for about five inches and a leader, consisting of the same cordeau, is run along the top and the split ends of the separate holes are carefully wrapped around this leader. If several rows of holes are to be shot at the same time, it is necessary to either leave enough cordeau sticking out of the back holes to extend to the leader over the top of the front holes or to run a second stringer across them also and loop the two leaders together at one end by means of a little brass sleeve. In order to shoot, all that is then necessary is to place an ordinary blasting cap with fuse at one end of the leader and the whole shot goes off instantaneously.

At the mines of the Cornwall Ore Bank Co. we have been using the cordeau two months, being as yet the only users of it in this country, although in France, where it is manufactured, they have used it for several years. We have made a dozen big shots. Before attempting to use it, however, we tried it out in the open. It is surprising what a terrific explosion a short piece will make when detonated. A two-foot piece laid on top of a powder box will blow it all to splinters; however, letting a locomotive run over it repeatedly has no other effect than to flatten it out, and applying a match to some of the cordeau powder gives no results but to make a black smudge which immediately goes out of itself. Our first shot consisted of five 40-ft. holes. The second of twenty-seven 40-ft. holes. The last one consisted of seventy-two 30-ft. holes by which 30,000 tons of heavy magnetic iron ore was displaced.

The makers claim that the rate of travel of explosion in the lead tube is 17,716 ft. per second, faster than that of 40% dynamite itself. By the use of this exploder we get greater efficiency from our dynamite,

mostly due to the fact that the powder is detonated throughout its entire length and we have therefore cut down the amount of powder used 10% and have not yet reached the limit. The lead tube makes the explosive absolutely water-proof. The handling of the same when loading is very much simpler than is the case with exploder wires and does not require the supervision the latter do. Also, because there are no wires to worry about, the loading and tamping are much expedited.

Finally, the remarkable fact of cordeau is that it not only promotes the 'safety first' idea by eliminating the real danger in blasting (the mercury cap), but it also is much simpler to handle, cheaper, and more efficacious.

Reviving Oil Wells

The use of nitroglycerine to increase the flow from oil wells has been so long known that it is common practice. A more recent development which promises to be of great importance is the use of compressed air for increasing the flow. The theory upon which it is based is that if the original rock pressure is put back upon the rock the flow of oil through it will be greatly accelerated. In actual practice the method followed is to cap a well in the usual way and connect it with an air-compressor. The compressor is run at full speed until the most satisfactory degree of pressure is reached, and then it is only operated to the extent necessary to keep the pressure uniform. The flow of oil from the surrounding wells is thus greatly increased, and in one case a group of wells was raised from an output of about 40 bbl. per day to over 40 bbl. per day. The degree of pressure needed has to be determined by experiment, and when the point is found at which the greatest flow is attained, the pressure is maintained at this point. In practice it has been found, for example, that a 14 by 20-in. compressor will serve to properly stimulate the flow of a group of 40 wells. The air is only used on certain of these, and the pumps are operated upon the remainder in the usual way. Patents covering the use of air for this purpose have been obtained by Smith & Dunn, of Chicago, and the process is being applied to over 1000 wells in various places between Pennsylvania and Texas with results that are reported to be uniformly encouraging. In some cases wells which have not yielded oil for many years have been caused to produce again. There is some question as to the validity of the patents and many other operators are also using the method for stimulating the flow of their own wells.

The production of crude barite in the United States in 1913 was 45,298 short tons, valued at \$3.45 per ton, according to the U. S. Geological Survey. The imports of crude barite entered for consumption amounted to 35,840 short tons, valued at \$1.71 per ton. Of these imports 82 short tons were entered at San Francisco.

Economical Sliming by Grinding Pans

By M. G. F. SÖHNLEIN

In Mr. Alfred James' review of progress in gold ore treatment during 1913, which appeared in the *Mining and Scientific Press* of January 3, 1914, the author refers to my article in *The Engineering and Mining Journal* of September 27, 1913, describing the evolution of the present grinding-pan practice at our mill. Since Mr. James believes that my grinding-pan results deserve the attention of the industry, I feel myself obliged to explain everything that may have left some doubt as to the actual performance of these pans. In this, as in the previous paper, only the metric ton of 1000 kilograms has been used.

Character and Quantity of Feed

At the time when I wrote the paper mentioned (May 1913) the pan had been running for two months in the way I described. The quantity of tailing from the old mill was computed as follows: In one unit of the plant I was treating 50 tons of pyritic ore per day, which after roasting was reduced to 40 tons, and in the other unit a maximum of 22 tons of oxidized ore from the upper levels of the mines. Preliminary grinding of both kinds of ore was done in No. 5 Krupp ball-mills, and certain middling-products from the concentrating machinery were reground in Huntington mills to about 40 mesh. After taking out a maximum of 10 tons of concentrate and rich middling for roasting and re-dressing, the balance of 52 tons was sent to the tailing-mill, of which I described the regrinding and sand-concentrating department. In the tailing-plant about two tons of concentrate was recovered from the Overstrom tables and the slime-plant, so that the final tailing amounted to at least 50 tons. I am absolutely certain about the grading analysis of this material, because the tables in the tailing-mill were working some time before the pan was started, and after being treated on these tables the pulp overflow from classifiers and cones was made to pass an automatic sampler, which takes a cut across the whole stream every 70 seconds, traveling at right angles to it and at an even velocity. Therefore I had a perfect control on the performance of the pan: knowing how much the average quantity of -200-mesh product was in the daily sample, any increase of this material was due to grinding of sand by the pan.

The quantity of pyritic ore treated was exactly known, because the ore is delivered at the plant in railroad cars which are weighed on platform scales when arriving. From daily laboratory tests on a sample of the ore ground during the past 24 hours, the loss in weight through roasting is known to average 20 per cent.

That part of the mill which treated oxidized ore was not run all the time. The ore supply was irregular on

account of the work in the mines being confined to development at that time. This department could only be run when there was ore, and then a quantity of 50 trucks of 440 kg. each was treated in 24 hours. The gangue of this ore contains slate, quartz, limonite, and other iron oxides, more or less decomposed feldspars, and a little pyrite. I may give an idea of its hardness by stating that it is at present being crushed in a 10-stamp battery, of which the output is 3.25 tons per hour when discharging through a 1.18-mm. screen. The stamps drop 98 times per minute, the height of drop being 6½ in., height of discharge 4 in., and weight of stamps 1050 pounds.

All my figures and screen tests refer only to those days when both parts of the old mill were running. If finally no +60 product was found in the daily tailing sample, it is obvious that the pan must have reduced all the sand to pass a 60-mesh screen, and about 30 tons of it to -200 mesh, as shown below:

SCREEN TEST ON MILL TAILING SAMPLES

| Quantity of tailing, 50 tons per 24 hours. | | |
|--|-----------------------------------|----------------------------------|
| Screen. | Before installation of pan, %. | After installation of pan, %. |
| +200 | 81.5 | 21.2 |
| -200 | 18.5 | 78.2 |
| | 100.0 | 99.4 |

The increase in -200-mesh product, due to grinding done by pan was $(0.782 - 0.185) \times 50 \text{ tons} = 29.85 \text{ tons}$. I hope it will now be well understood that the pan really slimed 29.85 tons, and not only one-third of it, as Mr. James infers in his paper. I have dwelt rather long on this subject, but my only reason has been to prove that there is no guesswork about the quantity of material treated in our plants, and the grading analyses given in the previous paper.

At present the pan does not grind the same quantity, because since October of last year that part of the mill for the treatment of oxidized ore has been closed down, and this ore is now treated in much larger quantities in a new installation with its separate grinding pan and slime plant. At present 40 tons of roasted ore is being treated in the tailing mill, of which the pan grinds 20 tons to -200 mesh. I have given up sliming all the sand, because it was found that the poorest sand-tailing from the Overstrom tables always contains less tin than the final tailing from the slime-plant. Therefore it is useless to grind this material, and by running about five tons of the poorest sand to waste, the extraction of tin has been improved.

I must admit that I was working with favorable material when sliming about 30 tons per day in the pan. Roasted ore is always easy to grind, and the oxidized ore is not hard. But at many Australian mills

the pans are likewise handling roasted ore, and their results are not as good as those obtained here. As I said in my previous paper, there are reasons to believe that I had not reached the maximum capacity of the pan when sliming 30 tons; less water in the feed, heavier shoes, a larger grinding surface, and greater muller speed would probably have improved the grinding work. Further, it must be borne in mind that this pan is a rebuilt amalgamating machine, changed into a fine-grinder by crude make-shift means, and if a pan were specially designed along the lines of my indications, it would doubtless be more efficient.

When operating the pan without any special feed device it was impossible to slime more than 2½ tons per 24 hours. I did everything possible: thickened the feed pulp to 80% moisture by discharging the spigots of the dewaterer intermittently, run the muller at seven different speeds varying between 26 and 70 r.p.m., tried several heights of discharge, and changed the position of the baffles, none of which gave satisfactory results, and the pan was about to be sent to the scrap pile, when I noticed a cut of a Colorado Iron Works pan in Richards' 'Ore Dressing,' showing the central feed pipes. When these had been put in, the pan became serviceable, but its performance was not yet satisfactory.

I noticed with some satisfaction, when reading A. W. Allen's experience with an amalgamating-pan as a fine-grinder ('Cyanide Practice, 1910 to 1913,' page 189) that I do not stand alone with my failure to make such a machine grind. Mr. Allen says: "Personally I have done everything in an endeavor to coax even a moderate duty out of this type of pan, but all to no purpose. * * * The maximum output I could get on ordinary quartz ore and with the pan fitted with new shoes and dies and a Wheeler discharge was about three tons slimed per 24 hours from 20 mesh." This figure agrees remarkably well with mine of 2½ tons.

Quantity of Sand in Circulation

I said in my previous paper, "the quantity of sand separated by the Dorr classifier is 38 tons, without considering the sand returned from the pan." My paper was not silent on the question of the returns, as Mr. James observes. To compute the total quantity of sand which passes during 24 hours from the tables to the pan, I must refer to the screen tests on feed and discharge, which, of course, were made under normal working conditions, that is, when the equilibrium to which Mr. James refers had been established.

| Screen, mesh. | Feed to pan. | Discharge from pan. |
|------------------|--------------|---------------------|
| On 20..... | 9.0 | 0.0 |
| 40..... | 11.0 | 1.0 |
| 60..... | 21.5 | 12.5 |
| 80..... | 24.0 | 22.5 |
| 100..... | 9.5 | 9.5 |
| 150..... | 13.0 | 11.0 |
| 200..... | 7.5 | 11.5 |
| Through 200..... | 4.5 | 32.0 |
| | 100.0 | 100.0 |

If the overflow of the Dorr classifier consisted exclusively of -200-mesh material, 32.0 - 4.5 = 27.5% of the discharge from the pan would be discarded at one passage. But the overflow has only 78.2% -200 mesh, and consequently 21.8% + 200-mesh product. Therefore an additional amount of $\frac{21.8}{78.2} \times 27.5 = 7.6\%$ of the pan discharge flows over as fine sand. This makes a total of 35.1% of the pulp ground fine enough at one passage to be eliminated from the circuit, and consequently, 64.9% is returned. Of this returned sand, another 35.1% flows over after the next passage, and 64.9% goes back to the pan, and so on. If the original feed to the pan is 38 tons, the total feed during 24 hours, including the returns, must be:

$$38 + 0.649 \times 38 + 0.649 \times 0.649 \times 38 + \dots \dots \dots 0.649^n \times 38$$
$$= \frac{38(0.649^n - 1)}{0.649 - 1} = \frac{38}{0.351} = 108.2 \text{ tons.}$$

Before the pan was used, one large-size Overstrom table could easily handle all the sand, but when the quantity had been so considerably increased by the returns from the pan, it was found necessary to use both tables, which then received about all they could treat.

It never occurred to me to check the total quantity of sand fed to the pan by a direct test, but have recently determined by timing the filling of a 15-litre bucket that it is equal to 73 tons under the present conditions, when sliming only 20 tons and discarding 5 tons without grinding.

Mr. James observes that it is difficult to realize how, if at one passage only 30% is slimed, the other 70% is to be slimed as well, and at the same time the new ore from the mill is crushed. I believe that this may be explained as follows: by discharging the pulp directly after it has once passed underneath the muller, instead of returning it by baffle-plates, so much time is gained that this accounts for the greater capacity. Be this as it may, it is possible, because I have done it for over six months, and am doing it today with two pans, though grinding smaller quantities. I shall refer again to this question further on.

Comparison of Screen Analyses

In comparing the screen test tables, one sees immediately that the increase of -200-mesh product in the discharged pulp is principally gained at the expense of the +20, +40, and +60-mesh sand. This is easy to understand, because if a pan muller squeezes a grain of say 0.3 mm. (40 mesh) between shoes and dies, it is almost certain that this grain will be disintegrated into almost impalpable powder. The finer sand more easily escapes the grinding action, because when the muller is engaged in crushing the coarser grains, it will probably be lifted a very small distance from the dies on which it should be resting, and thereby gives the fine sand a chance to reach the periphery without being touched. Then again, if fine grains get under the shoes, they will have a tendency to be broken into a few smaller particles instead of being pulverized like the

larger ones. It is fully corroborated by screen tests that the fine sand between +80 and +200 mesh accumulates in the pan-feed. Before the pan was used, the grading analyses on the products from the Dorr classifier were:

| Screen, mesh. | Sand, 38 tons. | Slime, 12 tons. |
|------------------|----------------|-----------------|
| On 20..... | 11.5 | 0.0 |
| 40..... | 14.5 | 0.0 |
| 60..... | 29.0 | 0.0 |
| 80..... | 19.5 | 0.5 |
| 100..... | 12.0 | 3.0 |
| 150..... | 7.5 | 6.5 |
| 200..... | 4.0 | 9.0 |
| Through 200..... | 2.0 | 81.0 |
| | 100.0 | 100.0 |

The grains between the limits of -60 and +200 con-

back to its proper pan. Every pan could be so built as to be most efficient for the size of sand it should comminute. The pan grinding the coarsest sand would probably have more capacity than the others, therefore to work under the most economical conditions it might be necessary to have three or four pans for the finer sizes instead of two, this detail being different for each kind of ore and also depending on the preliminary crushing.

Referring again to the question of grinding the returned sand in the same pan, I should like to make a comparison with a tube-mill working in closed circuit with a classifier. It is generally acknowledged that no separate tube-mill is needed to slime the oversize in the discharge from the first one, although in exceptional cases the latter practice has been adopted. I have no

FIG. 1. SECTIONAL ELEVATION OF GRINDING-PAN FED IN ORDINARY WAY.

Centre of pan around central cone is full of pulp. Grains of sand directed by the baffles to A have to settle the distance AB in the liquid to arrive at the grinding surface. C. Baffle plate. D. Grinding surface.

FIG. 2. SECTIONAL ELEVATION OF GRINDING-PAN WITH CENTRAL FEED CYLINDER.

Bottom of pan around central cone inside cylinder is dry. Grains of sand fed in the cylinder fall directly to A, where they arrive at the grinding surface without delay. B. Central feed cylinder. C. Grinding surface.

stitute 43% of the sand product of the classifier, and after mixing it with the returns of the pan, the quantity of this fine sand is as much as 54%, as shown in the screen test table on feed and discharge of the pan.

The Australian practice of using different pans for coarse grinding and sliming seems reasonable, because each pan can be so adjusted to suit the material it is grinding. This principle is very good, but it should be more elaborate to give real economy. For a large installation, I believe the following arrangement would prove very effective: a different pan should be used for every size, namely, one to reduce only +40-mesh sand, another -40 to +80, and perhaps a third one to grind only -80 to +200-mesh material. The product from these grinding machines should then be returned to the sizing and classifying system, which could be simply and efficiently made of two Callow screens and one mechanical classifier, and the oversize from each screen and the classifier should be brought

grading tests to publish from personal experience with tube-mills, and have compiled a small list of screen analyses on feed and discharge from tube-mill practice in different parts of the world, which show the increase of the quantity of finest product obtained at one passage through the mill.

In compiling these data I have tried to be entirely indiscriminating regarding the performance of the tube-mills; my only purpose has been to obtain figures from many various districts. The average of the eight examples gives 29.8% of the feed slimed at one passage through the grinder, against 27.5% by my grinding pan. Example No. 2 is very instructive. The tube-mills in question receive a feed, of which only 7% is coarser than 60 mesh, and due to this have an abnormal small duty. This proves that whether the pan or tube-mill is used, the main difficulty in fine-grinding consists in reducing the -60 to +200-mesh sand to slime. To compare the quality of grinding of pan and tube-mill, regardless of power and material consumption, I should like to know if in the tube-mill feed the same accumulation of the fine sand is noticed as with the pan. Although not having data at hand from which I can make a definite conclusion, I have a strong conviction that this really is the case, based chiefly on the reduced output of tube-mills working on fine sand only. Now, if the quality of grinding work of tube-mill and pan is so similar, why should one machine have more difficulty in handling the returns than the other? Besides, I believe to have proved by my pan-results that the difficulty does not exist.

I can give a satisfactory explanation to Mr. James' observation, that although there is more +100-mesh product in my pan discharge, my results seem to be better than in Australian practice. As I understand, the pan in vogue in Australia has its return classifier connected with it, while I use a separate classifier outside the pan. The coarse sand which needs further comminution remains inside the Australian pan, until it is ground fine enough to flow over in the discharge lip, whereas I discharge this material with the fines to elevate it to the Dorr classifier.

Central Feed

I must confess that I think very little of the argument from Australia that "the centrifugal motion was such that the feed was found to be sent from the centre between the shoes and dies to the periphery anyhow." The only natural movement of the pulp in the pan is from centre to periphery, and it is just this movement which should be fully utilized to make the pan grind properly. During the passage from centre to periphery on the grinding surface the pulp stands the best chance to be caught by the entire width of the shoe. Now let us see how a pan grinds which is not centre fed. The pulp is introduced opposite to the discharge lip, rises to the baffle-plates, which subsequently direct it to the centre.* From there it is supposed to pass between shoes and dies to the periphery to be discharged. This is nothing but centre feed in disguise. If the pulp is not directed to the centre by the baffles, no grinding will result. Now, it is certainly not correct to first make a mistake and to afterward use baffles as a remedy; it causes loss of time by keeping pulp in circulation before it comes to the grinding surface at the contact of shoes and dies, and here 'time is capacity.'

In a pan with central feed the bottom inside the central cylinder is entirely dry, one sees the pulp falling between the projecting points of the shoes and dies, from which it is directly drawn away by the suction from the revolving muller. But during this rapid passage to the periphery the grains are sure to meet the shoes, because they cannot pass above the muller, every communication between the centre and the pan body being closed. On the other hand, if the centre of the pan is open, the level of the pulp at this point stands above the muller. The feed, be it brought to the centre by baffles or pipes, does not come directly to the clean grinding-surface, as with the centre-fed pan, but falls into a liquid where the coarse grains must first settle before they can come on the dies. This settling is a delicate question: first, the specific gravity of the pulp in which the settling must take place is high; and, second, the grains are directly submitted to the action of the centrifugal force caused by the revolving muller, which will draw some of them, and I believe the greater part, over the shoes

*'Grinding-Pan Practice at Kalgoorlie,' by M. W. von Bernerwitz, *Mining and Scientific Press*, May 17, 1913.

instead of through the open segments between them, where the only possibility of grinding exists. The accompanying sketches elucidate this. I believe I have sufficiently proved, first by the results of my grinding-pan, and further by argument, that a forced central-feed arrangement is an essential feature for real economical work with pans.

Finally, I will use this opportunity to make a few observations on the reply of Mr. von Bernewitz to my letter in the *Mining and Scientific Press* of December 6, 1913. I saw in his sketch that the coarse sand from the return-classifier is supposed to be drawn in by the muller. It is not drawn in, but settles by gravity, because it cannot flow over in the classifier. Then it is kept in circulation at the periphery of the pan until it has sufficiently risen to reach the baffles, and only then it comes back to the centre where it can come to the shoes and dies. The grinding pan can be compared with a centrifugal pump: with both, the maximum suction exists in the centre, and at the periphery, where the discharge should be, there exists only a repellant action. Therefore, it is impossible that the revolving muller can in any way be an agent for sucking the coarse sand back to the grinding surface in the pan.

As to the paraboloidal shape of the pulp surface, a look into a text-book of theoretical mechanics will prove that any liquid, contained in a cylindrical vessel in which a stirring motion parallel to the circumference is acting, must assume this shape. Of course, baffle-plates interfere with the regularity, but a depression in the centre always exists, and the pulp cannot keep level, as Mr. von Bernewitz believes. There is no reason whatsoever for the pulp in a sliming pan to behave differently in this respect from the pulp in the stage-crushing pan. I have noticed the central depression with every pan I have seen working.

Synopsis of article, 'Economical Fine Grinding in Pans,' discussed by Alfred James in 'Progress of Gold and Silver Ore Treatment During 1913':

In a new plant for concentrating tailing from tin ores, erected in 1912 at the reduction works of the Compañía Minera de Oruro, at Machacamarca, Bolivia, a mill was needed for grinding the sand in the tailing to -200 mesh. On account of the small quantity to be handled, a tube-mill was out of the question, and it was decided to install a pan. The pan in question was a 5-ft. standard amalgamating-pan, and when tried as it came from the factory, the maximum capacity which could be obtained was 2½ tons of sand slimed per 24 hr. After a feed device with pipes which delivered the pulp in the path of the mullers had been fitted to the pan, the duty was raised to 7 tons slimed per 24 hr. When a sheet iron cylinder was fixed on the muller plate, all openings in this plate were closed, and the feed introduced inside the central cylinder, the grinding improved to

such an extent that the pan reduced 30 tons of sand to -200 mesh, with a power consumption of 6.26 hp., and the muller made 60 r.p.m.; 0.67 lb. of iron was used for shoes and dies for comminuting one ton of sand to -200-mesh product. A cost of \$0.30 per ton slimed was calculated after two months' running.

FLOW SHEET OF REGRINDING PLANT

Capacity, quantity of moisture in the feed, and number of revolutions of muller are closely related, and for every feed a critical speed of highest efficiency exists. The material ground was not hard, the greater part of the sand came from roasted pyritic ore, and the balance from soft oxide ore. The tailing-pulp was delivered by an elevator to a Dorr classifier, which sent its overflow to the slime plant and the sand to two Overstrom tables, which recovered a small quantity of concentrate. All middling and tailing from these tables went to the pan after being dewatered in a small spitzkasten to 48% solids. The discharge from the pan went back to the same elevator, and the sand which had not been ground fine enough at one passage through the pan was returned to the tables by the Dorr classifier, and subsequently to the pan, until all had been ground so fine that it could flow over into the classifier.

The diamond is the most impenetrable of all known substances, and will scratch any other stone or the hardest steel. During his lecture at Kimberley, before the British Association, Sir William Crookes squeezed a diamond between two blocks of steel until they touched, without the slightest injury to the stone, although the pressure is said to have been 170 tons per square inch. Gardner F. Williams, late of the De Beers mines, witnessed the experiment, which thoroughly illustrated the impenetrability of a rounded diamond. No doubt, however, an octahedron formed stone would not have stood the test.

The De Beers diamond mines contribute \$3,600,000 per annum to the revenue of the Union of South Africa. At the present rate of production, the mines will last for 50 years or more.

COLUMBIA SCHOOLS OF APPLIED SCIENCE IN 1914 AND 1884.

Columbia School of Mines, 1864-1914

Columbia University, or Kings College, as it was then known, was founded in 1754. The few buildings in which the College was housed stood just west of the present Woolworth building, and in the midst of what were then broad meadows on the outskirts of the city of New York. During the Revolution, the buildings were used by both American and British troops as barracks and for hospital purposes, and it was not until 1784 that they were restored to college uses. For some reason the institution did not flourish greatly on this site and in 1857 it was removed to Forty-ninth street, not far north of the present station of the New York Central railroad. The wisdom of the change was at once demonstrated, for the College that for nearly one hundred years had seldom had more than 125 students in attendance, a few years later had nearly ten times as many.

Establishment of School of Mines

The establishment of the School of Mines was the result of the efforts of Thomas Egleston, who had studied at the Ecole de Mines in Paris, and on returning to this country was full of enthusiasm for the establishment of a school of mines in New York. In March 1863 he published a plan for a school of mines and metallurgy embodying a three year course of instruction, both theoretical and practical, in the subjects relating to mining and metallurgy. Some of the trustees of Columbia College became interested in the plan and a committee consisting of John Torrey, William Betts, and George T. Strong was appointed to consider the matter. The committee made its final report on December 21, 1863, and the trustees adopted resolutions establishing the school, appointing Thomas Egleston professor of mineralogy and metallurgy, and entrusting him with the work of organizing the school.

The School grew so rapidly that new quarters had to

be provided for the second year, and a vacant wall paper factory nearby was secured and equipped. Accommodations were provided for 72 students and 89 were in attendance during the second year. The third year the trustees of the College were sufficiently convinced of the success of the new School to authorize the construction of a special building, and John M. Newberry was appointed professor of geology. It was not long before a fourth year was added to the curriculum, but as a fourth year course was thought too long, this was designated a 'preparatory course' in order not to appall the students.

The School entered into a new period of development when the University was moved to its present site on Morningside Heights in 1897 and mechanical limitations of cramped quarters were removed, the development of the School then becoming even more rapid. The work of the School found ready support, and funds became available for laboratory equipment that had long been needed. Laboratory instruction in ore dressing, for example, was first possible on a large scale in the more spacious quarters available on the new site. A few years later, through the generosity of the Lewisohn family, funds were provided for the construction of a special building to house the departments of mining and metallurgy.

The growth of the other engineering schools has been so great in the past 25 years that in 1896 the form of organization was changed and the schools of engineering and chemistry were set off from the School of Mines, the three, however, remaining under the jurisdiction of a single faculty now called the Faculty of Applied Science. The present organization therefore consists of:

1. School of Mines, with courses leading to the degrees of Engineer of Mines, and Metallurgical Engineer.

2. The School of Engineering, with courses in civil engineering, sanitary engineering, electrical engineering, and mechanical engineering, leading to the degrees of Civil Engineer, Electrical Engineer, and Mechanical Engineer, respectively.

3. The School of Chemistry, with courses leading to the degree of Chemist and Chemical Engineer.

The buildings of the university proper number over twenty, and of these the following are particularly devoted to instruction in the courses taught in connection with the School of Mines.

New Building

The School of Mines building, erected in 1904, is 145 by 57 by 100 ft. in size. The entire building, with the exception of three rooms, is occupied by the departments of mining and metallurgy. On the left of the entrance is the mining museum; on the right, the museum of metallurgy. The museums contain models of mines, mine plants, smelting furnaces, and metallurgical appliances, together with a collection of metallurgical products. On the two basement floors are the ore-dressing laboratories, provided with appliances for concentrating and testing ores on a small scale, and for crushing ores preparatory to treatment in the con-

centrating plant. These laboratories also contain a number of full-size concentrating machines, which are examples of the principal types of apparatus used in modern concentration works. On the second floor is a drafting room, the reference library of the department of mining, the non-ferrous and electro-metallurgical laboratory, containing roasting and crucible furnaces and amalgamating and bleaching apparatus for dry and wet metallurgy, and the library of the department of metallurgy. The third floor is occupied entirely by the department of metallurgy: the iron and steel laboratory, provided with electric and gas furnaces, pyrometers, and other apparatus, for experimental work and the heat treatment of iron and steel; several rooms devoted to metallographic work; an analytical laboratory, dark-rooms for photography, and officers' studies. On the fourth floor are the assay laboratories; also, separate rooms for crucible furnaces and western coal-fired muffles, a room for the preparation of assay charges, and a weighing room provided with a number of balances.

The School of Engineering building, erected in 1896, is 150 by 57 by 100 ft. In the sub-basement are the bituminous materials' research laboratory and road materials' testing laboratory of the highway engineering

VIEWS OF ASSAY, CHEMISTRY, ORE TESTING, AND STRENGTH OF MATERIALS LABORATORIES.

department; also the storage battery room and the supply room of the department of electrical engineering, as well as the gas engine room and stock supply room of the department of mechanical engineering. In the basement are the machine laboratories (direct and alternating current) of the electrical and mechanical engineering departments. On the main floor are the reference library of the departments of civil, electrical, and mechanical engineering; the electrical engineering museum and lecture rooms, the museum of the civil and mechanical engineering departments, and the testing materials laboratory of the department of civil engineering. On the second floor are the drafting rooms of the department of civil engineering, a library, and a large lecture-room. On the third floor are the instrument laboratory, the drafting rooms of the department of electrical engineering, and a reference library. The fourth floor is devoted entirely to the department of engineering drafting. In the attic is a blueprint-room with large rolling frame and tank.

Havemeyer Hall

Havemeyer hall, erected in 1896, is 205 by 80 by 100 ft. The entire east wing of the first floor is occupied by the Chandler Chemical Museum, showing in specimen form the evolution, not only of the science of chemistry, but of the chemical and allied industries. The rest of the large building is taken up by the laboratories, administrative offices, lecture-rooms, the science seminar, and a library of books and journals devoted to pure and applied chemistry.

Fayerweather hall, erected in 1896, is 150 by 57 by 100 ft. The building is occupied by the departments of physics and astronomy.

Schermerhorn hall, erected in 1896, is 205 by 80 by 100 ft. It is occupied by the departments of geology, mineralogy, botany, and zoology. At the left of the entrance hall is the museum of economic and physical geology, at the right the Egleston museum of mineralogy. Two lower floors are occupied by museums, laboratories, and special research-rooms for invertebrate paleontology, stratigraphic geology, mineralogy, and blow-pipe analysis. The second floor contains the general laboratory of inorganic geology and petrography, special laboratories, the lecture-room, and the library of the department. The third floor is mainly occupied by the department of botany. The upper floor is devoted to the department of zoology.

The field work of the School of Mines consists of summer courses in surveying and in mining and mine surveying. Camp Columbia, the summer school of field work and surveying, is situated in the Berkshire hills about seven miles from Litchfield, Connecticut. It comprises a tract of 500 acres of land and a group of buildings sufficient to house ten or twelve instructors and 180 students. An administration building, an observatory, a fireproof instrument house, three dormitories, a mess hall, a Y. M. C. A. building, and a building containing laboratories and baths are provided.

Instruction is given for a period of about fifteen weeks each summer, between June 1 and September 15, in surveying practice, hydrographic surveying, railroad surveying, office work, and map-making.

Not far away, near Roxbury Station, is Mine Columbia. This was first opened nearly 200 years ago, being first worked as a silver-lead mine and later as an iron mine. It has three adits and ten shafts and winzes, the lowest level being 1100 ft. long. The vein is nearly vertical, and the workings are well adapted to the study of problems in mine surveying.

The trustees of Columbia University, in accordance with the unanimous recommendation of the Faculty of Applied Science, have recently determined to raise the requirements of admission to the Schools of Mines, of Engineering, and of Chemistry, and generally to elevate and strengthen the course of engineering and technical study, from and after July 1, 1914. These schools will then become advanced or graduate schools to which students of any branch of engineering, who have had a suitable preliminary training in scientific school or college, may come for the highest type of professional instruction and for training in methods of research.

After July 1, 1915, candidates for admission to these schools will be required to present evidence of such preliminary general education as can ordinarily be had only by taking at least three years of study in a college or scientific school of high rank. During 1914-15 candidates for engineering degrees will be admitted to the second year of the present course upon presenting evidence that they have completed the work of the present first year in addition to the existing entrance requirements. The Schools of Mines, of Engineering, and of Chemistry will, therefore, be placed upon the same academic plane as the present Schools of Law and of Medicine in Columbia University.

Revised Course of Study

The revised and improved program of studies to be offered in the Schools of Mines, of Engineering, and of Chemistry will be strictly professional and specialized for students who are candidates for any one of the several degrees offered in Mines, Engineering, and Chemistry. The college or scientific school course, completion of which will be required for admission to these schools, will be one including thorough instruction in mathematics, physics, and chemistry, as well as certain designated work in drafting, shop work, surveying, and mineralogy, together with courses of college grade and type in English, history, economics, philosophy, and in either French, German, or Spanish.

The purpose of this important change is to offer better and broader training for students of engineering, and to place the instruction in these professional subjects upon the same university plane as the instruction in law and in medicine. The recent rapid development of engineering practice, the wider social and public recognition now given to the engineering pro-

fession, and the frequent demands that men in executive and administrative posts shall have had an engineering education, make it imperative that the engineer of the future shall be a broadly educated professional man and not merely a technical expert. In order to insure this, it is necessary that the future engineer shall widen his intellectual outlook by continuing his general education considerably beyond the limits of the ordinary high school course. At the present time, even before the proposed new system is in operation, about half of the new students entering the Schools of Mines, of Engineering, and of Chemistry come from other colleges and universities, many of them with a bachelor's degree, and nearly one hundred students in Columbia University are already taking advantage of the existing opportunity to combine a college and engineering course covering six years of study.

The following is the program which has been announced for the fiftieth anniversary celebration:

Wednesday, May 27—Smoker at Columbia University Club, 18 Gramercy Park.

Thursday, May 28—12 m., Registration in Earl hall. 9 p.m., Reception in the University gymnasium; dancing.

Friday, May 29—10 a.m., Academic procession (alumni to assemble in Earl hall). 10:30 a.m., Convocation in the gymnasium with commemorative and scientific addresses, and the conferring of honorary degrees upon distinguished alumni. 1 p.m., Alumni luncheon in the University commons. 3 p.m., Inauguration of Chandler lectureship, H. L. Baekeland, lecturer, and award of Chandler medal. 4 p.m., Faculty teas in the several departments. 7:30 p.m., Anniversary dinner at the Waldorf-Astoria hotel, Fifth avenue and 34th street.

The foregoing program concludes the actual anniversary celebration, but all alumni are invited to the following events in commencement week:

The anniversary headquarters in Earl hall will provide opportunity for the arrangement of side trips and group meetings for Saturday.

Saturday, May 30—10 a.m., Meeting of electrical engineers. 3 p.m., Baseball game, South field.

Sunday, May 31—Baccalaureate service.

Monday, June 1—Class day and Senior dance.

Tuesday, June 2—Campus night.

Wednesday, June 3—Commencement day; conferring of degrees; alumni luncheon; costume parade; baseball game; beefsteak dinner; decennial celebration; singing on South court.

Imports of gold and silver coin and bullion and of the baser coins into France in 1913 were valued at \$203,417,000, against \$102,531,000 in 1912, and the exports \$84,050,000 and \$62,681,000, respectively. Imports of gold coin and bullion increased from \$49,244,000 in 1912 to \$128,296,000 in 1913. Exports for the two years were \$6,851,500 and \$14,453,384, respectively, so that in 1913, \$113,843,000 in gold remained in the country. Imports and exports of silver coin and bullion in 1913 were more nearly balanced, the figures being \$75,113,000 and \$69,505,000, respectively. The trade of the country was \$1,642,117,000 in imports, and \$1,326,950,000 in exports, the balance against the republic being \$315,167,000.

Zinc Smelting in West Virginia

The importance which West Virginia has attained as a zinc smelting state during recent years has not been generally realized. The only place in which zinc smelting is carried on is at Clarksburg, near the northern boundary of the state at about the central part. The town may at first sight appear to be in a peculiar situation as a zinc smelting centre since the ore deposits in Tennessee and Virginia are so situated with respect to the Alleghany Mountains that they are even less accessible than the regions of the Middle West. The town, however, has two great advantages as a zinc smelting centre. The first of these is that it is only a comparatively short distance from Pittsburgh, where

GRASSELLI SMELTER.

there is a large market for spelter in connection with the galvanizing industry. A second and even more important feature is that there is an abundant and cheap supply of natural gas. The three plants now in operation in Clarksburg each own gas properties but have not yet developed them as an abundant supply of gas is available at about 31¢ per thousand feet, at which price it is as economical to purchase it as it is for a company to develop a supply. Gas was discovered in the Clarksburg district about 20 years ago but it is only within the past decade that development has been rapid. Since that time the growth of the town has been remarkable and a number of important industries have been developed.

Two of the zinc smelting plants at Clarksburg are owned by the Grasselli Chemical company. One of these plants is a short distance south of the town, where 5760 retorts are now in use. Another and larger plant is at Meadowbrook, ten miles north of Clarksburg, where 6912 retorts are in use. These plants are in charge of Richard Ziesing. These plants are operated on ore from the Grasselli properties. The plant of the Perlman company, which employs 2736 retorts, is not of so much interest since it treats only scrap from galvanizing works. Details as to the metallurgical practice in these plants are not available for publication, since these companies have not seen fit to fall in line with the general practice among metallurgists of making public the processes employed. The general features of the Clarksburg plant of the Grasselli company can be seen from the accompanying photograph.

The Rush to the Hoco-Poco Diamond Fields

Although tales of the rushes of 'forty-niners' and of the Alaska stampedes are still fresh in the minds of all interested in mining, it is doubtful if any of them encompassed more vivid experiences than those of various Asiatic prospectors in the race to the Hoco-Poco Diamond Fields in 189— Mr. C. L. Larson has been good enough to attempt to reproduce the tale of one of these Oriental stampeders, practically as related to him by Mr. McK—, one of Asia's oldest and best known wanderers. The tale has all the earmarks of authenticity that usually characterize the stories of old but unsuccessful prospectors. It follows:

"Jerry Whaley, Jim Ferguson, and myself had been prospecting alluvials for some time, in the valley of Coptiko Copokus, in the Roos Coast range near the Bay of Bengal, when news came to us of diamond discoveries near Hoco-Poco bay. Although this field was some 1800 miles from us, we were well acquainted with its locality, it being close to the Straits of Malakai. As our placers had not proved up as well as might have been desired, we all decided to pull stakes and head for the scene of the new discoveries.

Rapid Transit in the Orient

"Ferguson voted for an overland journey, while Jerry and I determined on a water route and at once began the construction of two 'katamurangs.' These were practically simple rafts made of logs from banana trees. Two runners, as it pleases me to call them, were cut about 10 ft. long and curved upward slightly at the front. These were joined by three cross-pieces, the joints being lashed together by means of monkey tails. Bamboo slats provided a suitable floor, and a bamboo pole served as a mast, tiger skins being sewed together for sails. We then prepared a stock of provisions, and were about ready to start when Ferguson reappeared from a jaunt into the forests, leading a lively specimen of a giraffe, on which he declared he would make the journey. After rigging up saddlebags of monkey skins and stocking these with food, Jerry boarded his unwilling land yacht and smiled at us a good-bye as the wind took his sails and rushed him crashingly into the underbrush.

"After a final meal ashore, Jerry and I boarded our miniature ocean greyhounds and started out to sea 'neath fair skies and in a steady and strong wind. Things went well until three bells the next morning, when we were overtaken by a screeching southwester. Our barometer jumped from 37 knots instantly to 60, and by daylight we were shooting along at 68. About 10 a.m. we narrowly escaped cutting the P. & O. liner *Baltic* in two, she barely swerving enough at the last instant to clear our course.

"Late in the afternoon the sea calmed down and we kept ourselves busy for a few hours in consuming

food and sleep. About midnight we ran into a second storm, a genuine Australian 'willy-nilly' which slammed directly across our battered 'katamurangs.' The next twelve hours were critical ones as we raced through leagues and leagues of seas torn up by the 'willy-nilly' and strewn with wreckage. Luckily the seas were covered with phosphorus which greatly helped us to steer safely through the maze of dangers. Many times we were awed at finding our compass needles whirling around and around, and only when we noted large floating masses of magnetite were we able to subdue our fears of having wandered into haunted seas.

"The climax of danger came with a narrow escape from colliding with a German mail line steamer, the *Prinz Isaac* (I think), which, however, we passed with no more serious damage than the shaving off of her rudder. In the instant of passing her we had barely sufficient time to shout to her that we were bound for Hoco-Poco bay and would receive the claim for damages at that port.

"Shortly after this occurrence the 'willy-nilly' left us and we again enjoyed peaceful progress. As we neared the entrance to Hoco-Poco bay the next afternoon we thought our troubles were over, but on entering the harbor were attacked by a huge number of sharks and alligators. I at once turned my steed toward the deeper waters, but Jerry uncorked a bottle of a chemical which he had discovered on a trip of ours up in the Himalayas, and poured it out upon the waters. The seas instantly turned an indigo blue from the reaction of their sodium chloride on that precious solution; the sharks and alligators alike, promptly succumbed and their lifeless bodies were soon floating, bottoms up, out into the deep. This phenomenon, witnessed by so many natives, at once proved to them that we merited their respect and services, and they greeted us on landing in the manner desired by kings and queens. We had no sooner landed than we heard the crashing of trees and bushes afar off, the noise rapidly approaching us. To our surprise it proved to be none other than Ferguson on his giraffe, tired, bruised, but happy, and runner-up with us in the 1800-mile stampede, accomplished in 3 days, 7 hours, and 42 minutes.

Proof of Darwinian Theory

"The natives treated us very kindly, and interested us very much. They are known as 'Manikoos,' and are Darwin's only living proof of his startling theory of evolution—they still retain the first joint of the caudal appendage. The Hoco-Poco diamond fields were all that could be wished for. We netted \$750,000 each after six weeks work, after paying all expenses, including the damages for the rudder on the liner, the German government having sent seven regiments and two Gatling guns to the bay to collect same from us. All in all, the name Hoco-Poco brings pleasant recollections to me."

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Stripping Frozen Gravel

The Editor:

Sir—I have read carefully your editorial on this subject, and in the main think that you have hit the nail on the head. There can be no question about Mr. McCarthy's experience in thawing by means of heat, but it must be borne in mind that conditions on Bonanza and Eldorado creeks, which comprise the holdings of the Yukon Gold Co., are very different from the Klondike valley where the Canadian Klondyke operates, and also to the conditions existing on Dominion creek controlled by the Granville Mining Co. The Canadian Klondyke has an unlimited supply of water in the Klondike river, which runs through the property from end to end. This water can be diverted to practically any part of the property without great difficulty or expense. Also there are large areas of thawed ground on which to work during the time the frozen areas are being stripped and thawed by natural means. This never has been possible with the Yukon Gold Co. As a matter of fact there can be no comparison drawn between the operation or costs of these two companies. The management in both instances is good. On Dominion, where the Granville Mining Co. is preparing extensive areas for dredging, the conditions are again quite different from those met by either the Yukon Gold Co. or the Canadian Klondyke company. The overburden is of a different character; it contains far more ice and less matter, and for this reason is more easily removed. Considerably more cubic yards per inch of water employed may be moved.

Steam thawing has very little effect on 'muck' that contains a large percentage of ice, especially where the overburden is heavy—in excess of four feet. Dominion creek carries 'muck' for the greater part of its entire length in excess of five feet in thickness. The removal of such overburden cannot well be undertaken except by the use of water. It would probably cost three times as much to thaw five feet of 'muck' as it would five feet of ordinary gravel. In gravel the heat could be applied through points placed at least 10 ft. apart. To attain the same results in 'muck,' the points would have to be placed not more than three feet apart. Steam would have to be applied the same length of time in both instances. I think that the fairest way to put it is that under certain conditions thawing by steam is undoubtedly preferable; such conditions exist on the properties of the Yukon Gold Co. Under others the best and cheapest plan is to strip the ground by use of water and allow same to thaw naturally.

The latter applies to the Canadian Klondyke company, and Granville. When it is understood that practically every creek has its own peculiar difficulties, it is not exactly fair to quote costs on any particular creek expecting them to be the standard for the whole section; this also applies with equal force to methods. Both systems have their good points, and it requires careful investigation and a clear understanding of the peculiar conditions to be overcome to determine which system is best, or whether a combination of the two might not prove more satisfactory. I think that Mr. McCarthy's statement that "it was demonstrated that stripping and natural thawing could not be depended upon for large scale operations," is a bit too strong, as again, this depends upon natural conditions, which were evidently adverse where attempted by the Yukon Gold Company.

In regard to the costs of the Canadian Klondyke company, and the Granville, which were quoted at the meeting of the Northwest Corporation, Ltd., 10c. per cubic yard, there can be no doubt that this is an extremely low estimate. However, there are grounds for expecting it to be realized. For example, suppose a section of ground 21 ft. deep from grass roots to bedrock be taken to see how it works out. To start with, there would be available 70c. for each square yard of bedrock uncovered, based on 21 ft. or 7 yd. in depth. Now on such ground on Dominion creek one would expect to find fully 7 ft. of 'muck' and 14 ft. of gravel; one-third 'muck' and two-thirds gravel. By ground-slucing under efficient management, the upper one-third of overburden can, or should, be moved for 5c. per cubic yard. Therefore, the upper one-third, equaling $2\frac{1}{3}$ cu. yd. per square yard of surface, would cost $11\frac{1}{3}$ c. to move, leaving a balance of 58 $\frac{2}{3}$ c. to be applied to the removal of the remaining $4\frac{2}{3}$ cu. yd. of gold-bearing gravel, or 12.51c. per cubic yard. Now, granting that the removal of the overburden results in thawing the ground, it will be seen that 12.51c. per cubic yard is sufficient to dredge unfrozen ground, and also to provide for a reasonable rate of interest on the amount invested per cubic yard during such time as it is necessary to wait for natural thawing to be accomplished. To thaw by natural means 14 ft. of gravel and, say, 3 ft. of bedrock will require three summers, and the gravel must be free from all overburden or 'muck.' Also it must not be forgotten that one-third of the deposit has been permanently removed, which is not the case where steam is employed. The upper one-third, of course, contains no gold.

There are a multitude of ways by which the overburden or 'muck' may be handled, and a close study would be necessary before deciding on any particular plan, but in the main water under control (pipe, giants, etc.) give the best result. The cross-ditches mentioned are not efficient and are used only where the water has not been properly harnessed. The piling up of debris can be overcome without difficulty if necessary preparations are made beforehand, such as building flush

dams, and the burning of stumps, moss, and roots, instead of allowing them to be carried away by the water. The experimental work carried on by the Yukon Gold Co. in 1906, 1907, and also in 1909, is in reality no criterion, for such conditions on Bonanza where this work was carried on, are not adapted to thawing by stripping and ground-sluicing.

To refer again to cost of 10c. per yard, I think that there is no doubt that both the Canadian Klondyke company and the Granville officials have figured their estimated costs out on some such basis as I have attempted to illustrate, as there does not appear to be any other way for them to accomplish what they hope for. However, the Granville at first stated that the cost would be 18c. per cubic yard, which is a much safer figure. To follow out the same line as above, this would give them about 25c. per yard for working the gravel; which, if partly frozen, might still prove more economical than complete thawing by steam.

Altogether, I do not think it quite fair to the Canadian Klondyke company, the Granville company, or to the Dawson district as a whole to allow it to be definitely understood that dredging cannot be successfully carried on there for less than 30c. per cubic yard. The Yukon Gold Co. has no occasion to apologize for costs, for they are in all truth as low as the best sort of management can make them. Conditions are against them, and they cannot be changed.

EX-DAWSONITE.

San Francisco, April 28.

The Prospector in Mexico and 'the States'

The Editor:

Sir—I long to go prospecting again, so we decide to lease our mine, having found that many companies do this, following the old Cornish system; by this means they find out the exact value of their property very quickly, and the poor old overworked general gets a much needed rest.

My partner and I talk the matter over from all sides, and I plead to take our chances in Sonora, where the mining laws are just and fair, giving the prospector a chance. In the United States, apart from the difficulty of finding out where you are at, whether on private property or land not open to location, a prospector may perhaps forget that quail are out of season, and he is a law-breaker at once; or after tracking a deer for a few miles he finds it is a doe, and another law is broken. I believe strongly in woman's rights, and the idea of making Mormons out of those innocent animals by force of arms is scandalous. Government officials never seem to realize that after the deer and quail are gone (and they are fairly good at taking care of themselves), they can turn a few goats and turkeys loose, and there we are again; they never think of the great luck the Englishman had with the rabbits. Barbwire fences are a nuisance, too, when you are conducting a burro train, and in these cases I certainly admire my partner. His perfect command of the language appeals

to me. For myself, each time I see a picture of a buffalo, I shed a tear for his passing; with government protection he would surely clean up a few fences.

In my opinion there are only three chances left for a prospector in the 'States': 1. He can lease, and this is what many old-timers are doing, the married ones especially. 2. He can go on a still hunt for apexes, but this takes time, and he must have a well dressed partner to do the outside work; his own part must be to wander from one mine to another, working underground, until he finds one which has opened up a blind ore-shoot; of course it must be a recent discovery, otherwise the mine would not be working; then he posts his partner, giving him the general direction, and his share of the work is done. The partner, who meantime has the lay of the land surrounding, gets a bond on any property in said direction, and the lawyers do the rest, on shares, of course. 3. He can go 'high-grading,' which is not such a crime when all hands are laid off waiting for the decision to be reversed, and perhaps the rightful owner himself in on the play; law-breaking being the natural result of too much law.

Having a copy of the Mexican mining laws, we read it over carefully. We find that the districts are bounded by the watersheds as much as possible; each district has its mining agent, and for the sum of \$1, one can find out the standing of any monumented property, whether open to denouncement, or when liable to be. One can denounce as much ground as one wishes, and add to this at any time if still open. Title to said ground is secure as long as the owner pays his taxes. A prospector is happy in the knowledge that all the metal inside his boundary lines (which he has to monument and plainly mark) is his, and no enterprising brother in the next state can imagine that he has an apex and pass those lines. Said brother's lode can sprout spurs if it wishes, or can develop a case of dips, or get the heavens, or might fissure and take to angling around some; but it has to respect those boundary lines, and the only way they can juggle him into a lawsuit is for them to find the outcrop in the antipodes and raise into his ground. One can denounce a prospect on anyone's land, as the surface and underground rights are entirely separate, oil, coal, etc., excepted, as they ought to be. If you think there is mineral 1000 ft. or so underground, the Government will not interpose; its officers politely collect their \$6 per, and probably consider that your theories are your own affairs, possibly at the same time longing for a few more theorists to happen along. You can even form a company if you wish and start out after the widow and the seamstress; these latter will invite you in and divide their humble beans and tortillas with you, and will smilingly shake their heads. "Now, if the Señor had a few pictures of the saints, then perhaps—", and you will say good-bye a little shamefacedly, for you have learned that these people are wise in their ignorance; they get a nice long run for their money, at least. But

the revolution? Well, after all, it is quite a family affair; our neighbors are not fools by any means; they have no wish to kill the theoretical goose. The American who behaves himself is *persona grata* in their country, and a prospector with his burro or two, off in the hills, is as safe as a bottle of whisky in Heaven. As I say we look carefully over these mining laws, and rather to our surprise we find that it is a government leasing system, pure and simple, working so perfectly and smoothly that a mining camp lawyer is unknown, and I am willing to bet that nine-tenths of the mine owners of Mexico do not know that they are lessees.

JOHN WATSON.

La Caridad, Nacozari, Mexico, April 12.

Prospecting and Government Aid

The Editor:

Sir—I have read with a great deal of interest the discussion in the *Mining and Scientific Press* relative to the discouragements of prospecting and how to encourage it. The article by F. Sommer Schmidt, which appeared in your paper of April 4, contained an excellent suggestion on the system of government aid to prospectors and prospecting companies. Especially appealing is the action of the British Columbia government in building wagon roads to properties even before the tonnage had been developed. In contrast to this I may cite the experience of the Leesburg Syndicate which in 1890 was endeavoring to open a hydraulic placer property here. This syndicate built at its own expense ten miles of wagon road over the Leesburg summit at a cost of \$10,000. This road has ever since been used by the public. The prospectors and miners in this county alone during the past 30 years have made 200 miles of wagon road at their own expense.

One of your correspondents brings out the fact that with all due appreciation of the Geological Survey during the past it has not taken up work in a mining district until the mineral reputation has been established by a considerable amount of development. I believe that a system of having a permanent United States district geologist who would make frequent visits to localities where prospecting is being done, who would give advice where requested, and collect data of new developments, who would also make tests of ore for prospectors or have them made, would be of the greatest assistance to prospecting.

During the last annual session of the American Mining Congress a comparison was made of the federal aid given to agriculture and the amount given to mining. The amount given annually for the benefit of agriculture was stated to be \$17,000,000, the amount to mining approximately \$1,000,000. The Department of Agriculture has for many years past at great expense and effort published for free distribution more than 500 bulletins, the result of painstaking experiments relating to agriculture which have proved of great assistance to the farmers. May we not hope that the federal government through the Bureau of Mines, will in the

future make like experiments in mining, milling, smelting, and all matters pertaining to prospecting and mining, and issue for free distribution bulletins giving the aforementioned information?

O. E. KIRKPATRICK.

Leesburg, Idaho, April 23.

[We are glad to present this bit of experience direct from the field. The suggestion that the United States Geological Survey employ district geologists has much to commend it but fails to take into account differences in conditions. The work of the proposed geologists is exactly what is expected of the State Geologists and their staffs. None of us need wait for Washington to act. Get after your state legislature, which is nearer home and see that your own State Geologist is given funds to do this work. As to road building we wish heartily that it was possible to commute by cash payment much of the useless and wasteful assessment work now done on mining claims and thus build up a fund that could be used under proper supervision to build roads through our mining districts comparable to those in the Yukon and British Columbia. Possibly this can be brought about in connection with the mining law revision now under discussion. In theory our law leaves it to the prospector to build roads where they will do him most good and allows the work to be counted as done for the benefit of the claim. In practice the plan does not always work out well and we may well learn from our neighbors to the north.—EDITOR.]

Cost at the Commonwealth

The Editor:

Sir—In your issue of May 2, you print an excellent article on 'Milling Operations at the Commonwealth Property', by E. H. Leslie, in which it is stated that the total cost of mill construction was \$335,271. This is an error, the figure given being the entire cost for all construction work, including new shaft equipment, and power plant equipment. The cost of mill construction alone was \$241,070.81 as shown in accompanying statement of tabulated construction costs.

Mr. Leslie's article is so complete in every other respect, that it is unfortunate that we were unable to give him these detailed figures before the article was written.

EDGAR A. COLLINS.

Pearce, Arizona, May 6.

[The table of costs to which Mr. Collins refers will be found on p. 619 of the *Mining and Scientific Press*, April 11. The cost of the crusher plant, stamp-mill, and refinery alone amount to the \$241,070.81, and, as Mr. Collins states, the figure used by Mr. Leslie should have been stated to include power plant and other items.—EDITOR.]

Wages paid on Rhodesian mines are as follows: 1850 white employees, \$144 per month; 34,000 natives, \$7.20 per month. Dividends paid by all companies totaled \$2,545,000. Up to the end of 1913, Southern Rhodesia had produced minerals valued at \$121,000,000.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Sulphuric acid manufactured by zinc and copper smelters in 1913 was 296,218 and 336,019 tons, respectively, averaging \$6.87 per ton.

Osmiridium nuggets have recently been found in Tasmania. The largest were 1 oz. 17 dwt. and 1 oz. 15 dwt., the former being probably the largest in the world for this metal.

Candles, caps and fuse, carbide, and powder used in the Bunker Hill & Sullivan mines, Idaho, in 1913, cost 1.4, 1.1, 0.2, and 7.3c. per ton, respectively, in mining 436,060 tons of ore.

Cryolite, a fluoride of sodium and aluminum, is mined in Greenland and exported to Denmark. The production during the past five years is as follows: 5754, 4593, 7376, 10,609, and 8041 tons.

Seeger cones are used for the measurement of heat effect. They are made of silica, aluminum, and lime compounds for various temperatures. From the point of their collapsing in any kind of furnace the temperature is determined.

Electric switches in gaseous mines are liable to produce explosions if they are not properly designed and made. The U. S. Bureau of Mines recently conducted a number of tests with switches for mines. The permissible switch may be either of oil or of the explosion-proof types.

Molybdenite is recovered in Queensland and New South Wales. In February, a shipment of 8 tons, from Wolfram Camp, in the former state, and assaying 94%, was sold for \$2217 per ton, after keen bidding. It is reported that a process for the preservation of cordite in hot climates, involving the use of molybdenum, has been discovered in France.

There is no law in the United States against melting gold coin so as to entirely destroy its identity as money. The crimes against coinage consist in 'sweating,' or in any way removing part of the metal in the coin without rendering it unfit for circulation. It is, of course, a crime to attempt to recoin the metal when once melted, or even to have in one's possession dies or machinery which might be used for counterfeiting purposes. While coins may be used by jewelers in the British Empire, it is against the law to melt any coin. 'Sweating' coins has been done recently in Australia with disastrous results to those engaged in this illicit work.

Sections 1416 to 1422, inclusive, of the civil code, contain the general law of the state of California relating to appropriation of water. If the water is to be used for power purposes, an application must be made to and a permit secured from the State Water Commission before the water can be diverted or used. The law governing such applications may be found in the statutes of the extra sessions of 1911, pages 175 to 185, inclusive. Application forms and instructions may be had by mail from the Commission, whose offices are in the Mills building, San Francisco. The last legislature (1913) passed a new act making the appropriation and use of water for all purposes, including use by riparian owners, and use of percolating waters, subject to regulation by a new water commission, but this act has been held up by referendum petition and cannot become effective unless approved by the voters at the next November election. This act may be found in the statutes of 1913, pages 1012 to 1033, inclusive.

The rationale of bridge design was discussed by Charles Evan Fowler in *Western Engineering* for May. The article was accompanied by illustrations of ten different bridges throughout the world. The accompanying halftone shows a fine example of reinforced

VIEW OF GRAFTON BRIDGE, AUCKLAND, NEW ZEALAND.

concrete bridge work in Auckland, New Zealand, which was constructed in 1910. Dimensions are as follows: total length, 973 ft.; clear span, 320 ft.; greatest height, 140 ft.; height of span, 83.99 ft. from centre line of hinges; deepest foundation, 62 ft.; shallowest foundation, 18 ft.; and width of bridge, 36 ft., with 24 ft. of highway and two 6-ft. sidewalks. There are 2 major and 7 minor piers. The approaches are 20 and 22 ft. wide, respectively. There was used 330 tons of steel, 1130 tons of New Zealand cement, 2100 cu. yd. of basalt, 4050 cu. yd. of shingle rock, 230 cu. yd. of large boulders, and 60 cu. yd. of sand. For the falsework, 400,000 board feet of timber was used. In testing the finished structure, 292 tons of rock was loaded on one section, removed, and then two 16-ton steam rollers run across, showing deflections of only 0.143 in. and 0.083 and 0.066 in. respectively. The bridge was built in 32 months and cost \$205,000.

Special Correspondence

JOHANNESBURG, TRANSVAAL

DISCUSSION OF WORKING COSTS ON THE RAND.—CHEAP OPERATIONS AT SOME OF THE DEEP-LEVEL MINES, AND WHOLESALE MINING RESULTS.

Since the publication of the evidence submitted by the Chamber of Mines to the Economic Commission, on the future of the Rand gold-mining industry, the necessity of reducing working costs has been generally recognized. Some idea of the urgent need of a material reduction in the working costs, if very deep mining is to be successful, may be gathered from the January statement issued by the Chamber of Mines showing the yield, cost of working, and profit. The average working cost for 50 producing companies was \$4.36 per ton, an average exceeded by 31 companies, leaving 19 with a working cost below the average. The cheapest worked mines are those controlled by the Consolidated Gold Mines of South Africa. For instance, the average working cost at the Knights Deep was only \$2.76, and at the Simmer & Jack Proprietary \$2.80 per ton, which are the two most economically worked gold mines here. The Glencairn Main Reef mine, with a working cost of \$2.98 per ton, does not throw much light on the future working costs of the Rand, as the mining conditions are abnormal when compared with those likely to be encountered in future deep mining in the district. The same cannot be said, however, of the Simmer Deep, with a working cost of \$3.18 per ton, which may be looked upon as a mine fully representing all the features and difficulties likely to be encountered in the immediate future in deep mining. Most of the cheaply worked mines are those without any costs for development, simply because they are practically fully developed. Under this category are such mines as the Simmer & Jack, Glencairn, and Robinson. The Simmer Deep, Robinson Deep, and Rose Deep are, however, mines with working costs below the average, and all the items of expenditure and conditions to be encountered in deep mining here. The Simmer Deep has the low average cost of \$3.18 per ton milled and under existing circumstances may be said to be the most economically worked of any deep mine on the Rand, it being the deepest mine at present being worked here. That it is not a profitable mine cannot be put down to its working cost, but to its comparatively poor yield, which during January was only \$3.40 per ton milled. Then there is the Robinson Deep, also controlled by the Consolidated Gold Fields, with the low average working cost of \$3.96, although the mine has to contend with all the difficulties and expenditure likely to be encountered in future deep mining. In the Knights Deep, Simmer & Jack, and Simmer Deep, the Consolidated Gold Fields controls the most economically worked gold mines in the district, the first and the last named being good examples of what may be achieved under existing conditions in the direction of reducing working costs to the lowest limit. It may be emphasized that the yield at these two properties is only \$3.34 and \$3.40 per ton respectively, and probably this low yield is the cause of the low working costs. In both instances these costs have been obtained by what is known as the 'big milling policy' combined with an adequate number of tube-mills, and when such a policy can reduce the costs to about \$3 per ton it would almost appear as the policy likely to be most successful in the future deep-mining operations on the Witwatersrand. Wherever this policy has been adopted, working costs have been reduced, and in future deep mining here it is far more likely to succeed, than in any attempt to raise by artificial means the grade of the ore sent to the mills. It will be remembered that some time ago, the big milling policy was hoped to be improved upon, and working costs still

further reduced by merging several mines under one management, but up to the present this policy has not come up to anticipation. A policy of consolidation to be successful, a concentration of operations becomes absolutely necessary, otherwise it exists in name only and this would seem to be the drawback of this policy on the Rand. The East Rand Proprietary, Crown Mines, and Randfontein Central, are the three most striking examples of this wholesale policy, and so far the Crown Mines company constitutes the only instance where any serious attempt has been made at concentrating mining operations. In this instance the working costs have been reduced to \$3.70 per ton with prospects of still further reductions; but these concentration operations have in this instance cost such an enormous expenditure of capital that few concerns, even on the Rand, are in a position to undertake such a task. At the Randfontein Central the working costs averaged \$4.46 per ton, which was 10c. above the average of the whole Rand, despite the fact that the Company has by far the biggest mill. At the East Rand Proprietary the big milling and wholesale mining policy has been abandoned for selective mining with the result that working costs have advanced to \$5.36 and over per ton, with scarcely a corresponding improvement in the yield. The natural result follows that profits have fallen, and the future prospects of the concern become seriously imperilled by the reduction of the profitable ore reserves to at least one-half of the former estimate, that is, from 10,000,000 to 5,000,000 tons, a reserve scarcely ample for such a concern according to development ideas generally prevalent in this country. In conclusion it may be pointed out that working costs on the Rand are highest where the scale of operations is not in keeping with the size and importance of the property, such as for instance, at the West Rand Consolidated, Princess Estate, City Deep, and Geduld Proprietary mines, where the costs run from \$6 to \$6.12, as against \$4.36 per ton for the whole of the Rand. It must be concluded therefore that if future working costs are to be brought down to a profitable level the most likely policy will be that associated with wholesale mining, underground and surface concentration of operations, and last, but not least, big milling and large scale working which, as already shown, have in several instances brought down working costs to the low level of \$3 per ton below which, under existing conditions, it does not seem possible to go.

JOPLIN, MISSOURI

MANY NEW MILLS CONTEMPLATED.—SOME ENCOURAGING ZINC PROSPECTS. SITUATION IN THE ZINC AND LEAD DISTRICT.

Several new concentrating plants are to be constructed in the Missouri-Kansas-Oklahoma zinc and lead district in the near future, according to plans of various operators in different parts of the district. Despite rather low ore prices that have prevailed for some time, operators are more or less optimistic concerning the future. A number of new mills have recently been completed and placed in operation, and work on new ones is to start immediately. The Osceola Lead & Zinc Co. has started the construction of a 200-ton concentrating plant on the Riseling land, West Seventh street, Joplin. The former mill on this property, operated by the Waneta Mining Co., was burned about a year ago. The Osceola company took over this lease recently and has been developing it. Hand jigs have been used so far by the Osceola company in cleaning the ore, but these will be discarded when the new plant is completed. This makes the third mill operated by this Company, the other two being in the sheet ore district of the North Webb City, Missouri, field. The Waneta lease has produced \$700,000 in zinc and lead to date. New work is in virgin ground, and unusually good ore has been blocked out both in drilling and prospect driving. Recovery by the hand jigs has run as high as

12% sphalerite concentrate. J. R. Underwood, of Granby, Missouri, operator of one of the largest mines in that district, will soon commence the construction of a 150-ton mill some distance to the south of the main Granby district. Drilling has shown sphalerite deposits. Originally Granby was one of the heaviest galena producers of the district, but in recent years the galena production has been small. As a calamine producer, Granby leads all other camps of the district. Recently it has gained in importance as a zinc producer. The new development launched by the Underwood company promises to result in an increased output of zinc-blende. Another mill is to be constructed by the Lone Elm Development Co., operating on the Granby Mining & Smelting Co.'s land, Joplin. The plant will be used as a custom mill, handling ore from several small mines on the property. The Company has just started its third pump, two pumps having been at work for several months. On another part of the Granby land, one mile west of the Lone Elm tract, the Granby company is conducting some important development on its own responsibility. The Granby company has just purchased from the Excelsior Zinc & Lead Co. the Guveneur concentrating plant situated at the Four

CARSON-DODSON PROPERTY, MIAMI, OKLAHOMA.

Corner camp, several miles northwest of Joplin, and the mill will be removed to the Granby lease. In the reconstruction of the plant many improvements will be made. The capacity of the Guveneur mill was 150 tons per shift, but this will be increased to 250 tons by additional equipment. Other mills are planned by several companies, including the J. M. Short Co., operating at Oakland, northeast of Joplin.

Foreshadowing eventual mill construction, a number of important drill discoveries have been made recently. F. V. Wasserman and associates, consisting of Kansas City and Iowa people, have made three finds of exceptional richness on the Llewellyn land at Belville, Missouri. In view of the fact that deposits in this region have usually been found to be uncertain in dimensions, the richness of the new developments does not mean extensive deposits. However, as four holes have been sunk, three penetrating high-grade blende, it would appear that the tract is almost certain to become a producer. The ore shows a general depth of 118 to 145 ft., an average yield of at least 15% being indicated in the drill samples for the entire distance in all holes sunk. While some large producers have been opened in this immediate field, the tract on which the present Company is at work has never been prospected. In the Miami, Oklahoma, district a number of finds are reported. Recently the writer counted 23 prospect churn-drills in the Miami field, about 15 of them being in active operation, while the others were being moved to nearby leases where they would soon be placed in operation. The Miami field, once confined to a comparatively small area immediately north of the town of Miami, has broadened out, covering an area several miles square. Recent drill prospects in the Neosho river bottoms, northwest of Miami, show both zinc and lead ores at 50 ft. down to 200 ft. Already one new concentrating plant, owned by the McConnell & Barnes Mining Co., has been erected. This plant was put up solely on the strength

of drill samples. While the mill was being built a shaft was sunk to ore; the operators cut barren ground in shaft-sinking, but in extending a prospect drift they have opened good ore. The mill is now in operation and is producing. Drilling on the Connor estate, Central City, Missouri, has revealed calamine and lead at 50 to 72 ft. Childress & Co. are doing the work. Following several drill finds, a shaft has been sunk to ore, and a large pile of crushed rock is on the surface. Some 'turn-ins' of galena, occurring in large chunks, have been made.

KALGOORLIE, WESTERN AUSTRALIA.

THE LANCEFIELD MINE, PREPARATIONS FOR RESUMING OPERATIONS.—DEEP SINKING AT THE IVANHOE.—GEOLOGY OF EDNA MAY.—GREAT BOULDER RESERVES.—SONS OF GWALIA.—ASSOCIATED NORTHERN.—GOLD RETURNS.

The Kalgoorlie & Boulder Firewood Co., the new owners of the Lancefield mine, have 30 men employed overhauling the 300-ton treatment plant, which was in poor condition. Besides completely remodeling the furnaces, a new hoist, two suction-gas engines of 220 hp. each, and vacuum-filters are being added to the equipment. Alexander Porter, the chairman of the Firewood company and the biggest holder of its stock, is sparing no expense to give the venture a fair chance of success, and his enterprise in helping the mining industry in the present depression is fully appreciated. There is no question about size of the lode, as it averages 25 ft. in width, and has been proved to a depth of 1000 ft. on the incline. The ore-shoot is also 1200 ft. long, and has already yielded \$4,140,000 from 540,000 tons, or \$7.66 per ton, and, according to Bewick, Moreing & Co.'s estimate, there is 250,000 tons of ore in reserve of similar grade. There should be a good profit in the venture if strict economy is practised. The mine is in charge of John Dunstan, who has had a long experience in gold mining in this state; and the underground manager is Archie Long, who has recently held a similar position on the Great Fingall mine, but was formerly on the Lancefield.

The sinking of the main shaft of the Ivanhoe is being pushed ahead so as to get below the porphyry dike, which has impoverished the lode below the 2000-ft. level. The present depth of the shaft is 3015 ft. and it is to be sunk to 3500 ft., or well below the dike, into the quartz-dolerite, in which the lodes contain the best gold content. Owing to this intrusive dike the ore reserves during last year declined from 1,080,850 tons worth \$9.74 per ton to 991,400 tons worth \$9.24 per ton, a decline of 89,450 tons.

The Edna May mine at Weston's, 40 miles west of Southern Cross, has been giving remarkable returns and profits since June last. The total output to date is 14,689 tons for \$318,600, and dividends amounting to \$82,500 have been paid. A good deal of controversy has resulted regarding this mine, as it is in granite country, and geologists are of opinion that sooner or later the lode will be cut off. This opinion is backed by the fact that the Greenfinch company held the adjoining claim on the northwest, and granite has completely cut off the lode at a depth of 90 ft. The Edna May lode at a depth of 150 ft. is still strong and rich, although a 'floor' of granite 18 in. thick cuts horizontally through the vein at that depth, and if there are other floors, as in the Greenfinch, the life of the mine will be limited.

Although shaft sinking on the Great Boulder mine has been suspended for three years, since the main lode passed into the Golden Horse-Shoe ground at a depth of 2630 ft., the output and ore reserves are well maintained. During last year 212,205 tons of ore was treated, returning \$2,823,400, yet the ore reserves only decreased from 731,260 tons worth \$13.28 to 688,920 tons worth \$13.26 per ton. The life of the mine is certainly limited, unless the lode turns back from the Horse-Shoe as it did at a depth of 950 feet.

Acting on Malcolm MacLaren's advice, A. Wauchope, manager of the Sons of Gwalla mine, is sinking a prospecting shaft in the northern part of the property in search of a new ore-shoot. When J. MacDermott took charge of the mine in 1906, he found that there was no ore north of the main shaft below No. 8 level, and that at No. 4, the ore-shoot only commenced at 700 ft. south, the drift work at this point being in barren rock. Mr. MacDermott accordingly abandoned seven 24-acre claims on the north, and applied for a similar number on the south. The gold since won, and the dividends since paid, amounting to \$11,015,400 and \$2,579,600 respectively, recovered from 1,384,979 tons, have almost entirely come from these southern blocks. If Mr. MacLaren's theory is right, and a new ore-shoot is found at the north, the position of the mine, which is already excellent, will be further strengthened. The profits for the last 18 months have to a large extent gone in alterations and additions to plant, and when the work is finished, the increase in profits will be at once apparent. For instance, during February, expenditure on plant paid for out of profits was \$24,300, and this reduced the month's profit to \$7300.

The mill on the Associated Northern's Iron Duke lease at Kalgoolie has been permanently closed down, and part of the plant will be transferred to the Victorious mine at Ora Banda. The Iron Duke claim has been let on tribute to Shepherd and Trenwith, who, for five years, have been working a lode on the Hannan's Consols lease. During this period they have treated in a Huntington mill 59,000 tons of ore yielding \$155,000, or \$2.63 per ton at a profit. There is a large tonnage of oxidized ore in the Iron Duke assaying from \$3 to \$4 per ton, which the lessees expect to be able to treat successfully after paying the Company a small royalty. There is also a possibility of finding rich patches in taking out the ore wholesale. The main shaft on the Victorious mine is being sunk to 700 ft. and should be completed next month. The level continues disappointing.

The February return from gold mines in the state was \$2,194,100, and from the principal mines as follows:

| Name. | Tonnage. | Value. | Profit. | Dividend. |
|------------------------|----------|-----------|-----------|-----------|
| Great Boulder | 16,518 | \$219,600 | \$121,500 | |
| Kalgurli | 10,030 | 102,500 | 45,900 | |
| Ivanhoe | 14,991 | 137,400 | 38,200 | |
| Fenian | 2,886 | 45,400 | 23,900 | |
| Edna May | 1,929 | 38,000 | 23,600 | \$20,600 |
| Lake View & Star | 16,970 | 99,400 | 18,000 | |
| Bullfinch | 5,130 | 43,600 | 17,200 | |

WASHINGTON, D. C.

FATE OF BILLS CONNECTED WITH THE MINING INDUSTRY.—WATER-POWER AND ALASKA COAL LANDS BILLS.—COPPER EXPORTS.

It is not yet clear whether the program of the Democrats of the House, with reference to the remaining legislation of the session, shall include action on the bills that affect the mining industry, such as the codification bill, already passed by the Senate; bill for mining experimental stations; bill for mining rescue stations; and bills for the leasing of oil and gas lands which involve mining properties. It is certain that if any one of them meets with much opposition their passage will be difficult. It is not even certain what the fate of the codification bill will be. The sentiment in the House is not predisposed for legislation that can only go through by unanimous consent. Possibly, later, the disappointed ones will be in happier mood, and permit some of the much desired legislation to go through.

The House committee on public lands has reported out the water-power bill which interests so many mining men in the West. The bill authorizes the Secretary of the Interior to grant leases for water-power rights on the public domain, fixing royalties, and imposing restrictions to prevent monopoly. In states which have no public utility commissions, the secretary would be empowered to make regulations to insure fair rates to consumers. The Conservationists are said to be for the bill. Chairman Ferris of the committee has a letter from President Wilson favoring action at this session on this legislation, and also on the Alaskan coal lands bill and for the measure providing for the leasing of mining rights on the public domain. The desire is so general to shorten the session of Congress as much as possible that much of the Administration's program is being omitted.

The Department of Commerce has just made public its statement of the recent exports of copper from the United States, showing a high record, the exports for the six months ended March 31, 1914, amounted to 495,000,000 lb., or equal to the total for the calendar year 1906, and one and one-half times that for the year 1912. Copper ranks high among the articles exported from the country, being exceeded only by raw cotton and iron and steel. In the last calendar year raw cotton showed a total export of \$575,000,000; and iron and steel manufactures (including agricultural implements), \$330,000,000; while copper manufactures in the same year amounted to \$145,000,000. Present indications are that exports of copper manufactures in 1914 will approximate \$150,000,000.

PLATTEVILLE, WISCONSIN

LOW PRICES FOR ZINC ORES.—FUTURE PRICES PROBLEMATIC.—ORE SHIPMENTS IN APRIL.—MINES IDLE.

Diligent efforts on the part of large spelter consumers to avoid buying in quantity, constantly increasing stocks of metal in the hands of smelters, and a growing reserve of blende in the two leading zinc-ore producing areas of Wisconsin and Missouri, finally had its effect on the metal markets. Quotations on the closing days of April stood at \$4.80 per cwt. Blende suffered as a natural sequence, and the basis reported for the Wisconsin field at the end of the month, according to a report handed in by one of the leading buyers of the field, stood as low as \$34 and from this to \$38 per ton. The inferior grades suffered by comparison and producers were seriously discussing the advisability of shut-downs, while a noticeable curtailment was evident in all parts of the field. Shipments declined considerably and a conservative estimate of zinc ore carried over shows nearly 5000 tons of ore in bin, the highest quantity ever reported for the Wisconsin field. Prospect work with drills has been suspended, considerable underground development planned for this season has been checked, and new plants, upon which construction would now have been

well under way, is being deferred until market conditions have improved and prices warrant a normal production of zinc ore. Leading mine managers and ore buyers, thoroughly familiar with inside conditions, responding to personal interviews, think that no immediate relief is in sight, and look for no changes for the better within the next 60 or 90 days. Prices paid for April on the various grades produced in the field were given as follows: 30%, \$12.50; 35%, \$16; 40%, \$19; 45%, \$22; 50%, \$26; 55%, \$32; and 60%, \$38 per ton. Carbonate zinc-ore producers were out of commission entirely. Prices on pyrite were off as well, and shipments were half that usually reported for this period.

Shipments of ore from the various districts in April were as follows:

| District. | Zinc, Pounds. | Lead, Pounds. | Pyrite, Pounds. |
|---------------------------------|------------------|------------------|--------------------|
| Benton | 4,082,000 | 179,500 | 2,259,200 |
| Galena | 3,042,000 | 452,580 | |
| Cuba | 2,678,000 | | 141,520 |
| Livingston | 2,222,000 | 75,000 | |
| Hazel Green | 2,032,000 | 60,000 | |
| Platteville | 1,374,000 | | |
| Linden | 1,300,000 | 64,000 | |
| Shullsburg | 700,000 | | |
| Harker | 482,000 | | |
| Highland | 248,000 | | |
| Montfort | 160,000 | | |
| Mineral Point Zinc Company..... | 2,895,100 | | |
| Total | 21,215,100 | 831,080 | 2,400,720 |

Thirty-five mines, all with modern mining equipments, are idle at present. Two recently constructed mills are closed, with little prospect for operation in the near future.

TORONTO, ONTARIO

REPORT ON THE KIRKLAND LAKE DISTRICT.—CROWN RESERVE WINS LITIGATION CONCERNING ITS STOCK.—LEGISLATION ON EXPLOSIVES.—ALGOMA STEEL CORPORATION.

The report of F. H. Hatch, the well known mining geologist, who recently inspected the Kirkland Lake district, had been awaited with much interest, as likely to set at rest the prevalent uncertainty as to the prospects of the field. It is now announced by cable from England that his report will not be made public.

The Crown Reserve Mining Co. has won an important case, which after five or six years litigation in Canada, was taken to the British Privy Council on an appeal from the decision of the Canadian court, dismissing an action by John Black and others, claiming 569,950 shares, of which 338,807 had been disposed of. The Privy Council confirmed the judgment of the lower courts, ratifying the sales of stock made by the Company and declaring the remaining 231,143 shares to be its property. The final settlement of this long protracted litigation has considerably strengthened Crown Reserve stock on the market.

The need of more drastic legislation as to the manufacture, sale, and use of explosives has long been apparent, as accidents from carelessness or ignorance in this respect are of frequent occurrence. The dominion government, some years ago, ordered an investigation into the subject by an engineer specially brought over from England for the purpose; but as is often the case with official investigations, it led to no practical result other than the drafting of a bill which never became law. The principal difficulty in the way of effective legislation appears to be the conflict of jurisdiction between the dominion and provincial governments. It is now announced that another attempt will be made to deal with the matter. The Hon. Louis Coderre, Canadian minister of mines,

has given notice of the introduction of a bill on practically the same lines as that introduced by the former government, with some modifications as to provincial rights, providing for the regulation and control of the manufacture, importation and use of explosives. With the great expansion of the mining industry the necessity for such legislation grows more apparent year by year.

Though the secondary or finishing branches of the iron and steel industry continue much depressed, there is increasing activity in the basic branch. The Algoma Steel Corporation, Sault Ste. Marie, made new records in March, with an output of 30,420 tons of pig iron, and 29,640 tons of rails. It is running to full capacity with orders to keep it busy for several months. The Sydney plant of the Dominion Steel Corporation, which last January was only working to 40% of its capacity, operated up to 60% in April and finds business considerably improved.

NEW YORK

ELECTRIC SMELTING FOR REDUCTION OF BUTTE & SUPERIOR ZINC CONCENTRATE.—AMALGAMATED COPPER AND GREENE CANANEA.—HOLDING AND OPERATING COMPANIES.—DOME REPORT AND COBALT MINES.

Now that the infringement suit of the Minerals Separation, Ltd., against the Butte & Superior has been finally decided in the latter's favor, the Company has a clear field. Hayden, Stone & Co., the controlling interest, has secured the control of the American rights for the Johnson electric zinc smelting furnace, and with the high freight and penalty charge which the zinc concentrate now has to stand, there is a chance for the inception of electric smelting at Butte, though the furnace is better adapted for the treatment of complex ores.

The Amalgamated Copper Co., like the Anaconda company, reports a small deficit in its net receipts as compared with dividends paid during 1913, and, of course, for the same reason. This was made the most of as a 'bear' argument, but the stock rose in spite of it, probably because a less favorable report was expected. The reduction of the Amalgamated's surplus from \$24,000,000 to \$23,640,000 is scarcely reason for much consternation. The 1% dividend paid by the \$50,000,000 Greene Cananea Copper Co. may have puzzled some people, since the assets of the Greene Cananea consist of the stock of the Greene Consolidated Copper Co., a \$10,000,000 company, which declared a dividend of 50c. per share. The explanation, of course, is that the Greene Cananea shares are \$100 par value, while the Consolidated shares are \$10 par. The fractional prices of mining stocks are often a source of bewilderment to men familiar with general business, who suppose Utah Copper, for example, at 55 is at only one-half par, when it is actually at 5½ times par. The companies which expect active trading in their shares in the open markets commonly make the par value low, as the small investor would rather purchase 100 shares at \$1 each than 1 share at \$100.

The report of the Dome Mines, Ltd., for 1913 has just come out and shows that the gross proceeds from its ore milled were \$1,204,600. Operating costs amounted to \$615,500, leaving a net profit of \$591,780. The sum of \$134,084 was set aside for depreciation and maintenance, leaving a net surplus of \$457,700. The Dome got into a bad position through the optimism of the original management, which was not careful enough to develop a sufficient ore reserve in a deposit which was obviously of variable gold content; but its position has been since greatly improved, and it will undoubtedly eventually make good. The Trethewey (Cobalt) Silver Co. has taken an option until October on the West Beaver, 25 miles southwest of Fort William, and is reported to be about to spend \$50,000 in testing it. Canadian Gold & Silver is still being boosted.

General Mining News

ALASKA

CHISANA

The accompanying halftone shows the first picture published of the town of Chisana, the centre of the new placer district, which has been the cause of considerable notice from

STREET SCENE, CHISANA, ALASKA.

time to time. In another issue will be shown some prospectors at work during the past winter.

CORDOVA

A good deal of development has been done at the Bonanza and Jumbo mines, according to T. B. Tansey, of Kennecott. A tramway is being constructed between the latter mine and the mill. The concentrator has started work.

COUNCIL

Two shallow-draft dredges with 2½ cu. ft. buckets have been shipped from the works of the Straub Manufacturing Co., Oakland, California, to the Council district for the Flume Dredge Company.

JUNEAU

The Alaska-Gastineau Mining Co. will add to the electrical equipment of its power-house a 540-kva. synchronous motor and switchboard, the apparatus having been purchased from the General Electric Company.

VALDEZ

In the Granite mine, on Hobo bay, the gold-bearing vein is 14 ft. wide. It is probable that three Nissen stamps, a Lane mill, and 150-hp. power-plant will be erected.

ARIZONA

GRAHAM COUNTY

The Shannon Copper Co. reports as follows for the first quarter of 1914:

| | |
|--|-----------|
| Shannon ore treated, tons | 51,960 |
| Outside mines, tons | 13,254 |
| Copper, pounds | 2,922,889 |
| Gold, ounces | 397 |
| Silver, ounces | 19,480 |
| Net profits | \$46,676 |
| Cost of producing copper, cents per pound..... | 12.687 |

Results showed a decreased profit of \$54,962 compared with the last quarter of 1913.

GILA COUNTY

(Special Correspondence.)—The most important transaction that has occurred in the Globe district for many months is the purchase by the Iron Cap interests of the ground known as the Bird group, consisting of eleven claims, six of them patented. The claims adjoin the United Globe, Arizona Commercial, Iron Cap, and Superior & Boston, and are considered desirable ground—the Old Dominion, Superior & Boston, and other companies in the Globe district having negotiated for their purchase at different times during the past few years. The general manager of the Iron Cap, Frank A. Woodward, through whose negotiations the claims were finally secured by his Company, has wanted the ground for six years, although he says there will be no work done on the property at present. It probably will be held in reserve and later worked from the present Iron Cap workings, which it parallels on the north. The first payment on the property was made on May 9. The property was owned by Wenthrope Church and associates.

Globe, May 7.

PINAL COUNTY

The Ray Consolidated Copper Co. reports as follows for the first quarter of 1914: The orebody tributary to No. 1 shaft produced 59% of the tonnage; that at No. 2, 36%, and that at No. 3, 5%. Of the total tonnage, 11% was produced from development, 26% from active stoping, and 63% from reserve drawing. Mining and coarse crushing cost was 68.411c. per ton.

| | |
|---|------------|
| Development, feet | 29,832 |
| Ore milled, tons | 714,009 |
| Average copper content, per cent..... | 1.7978 |
| Recovery, per cent | 67.13 |
| Milling cost, cents per ton..... | 53.15 |
| Copper production, including 473,028 lb. in ore shipped to smelter, pounds..... | 17,707,374 |
| Net profit, including that from the Ray & Gila Valley Railroad | \$877,444 |
| Dividends | 543,964 |
| Net surplus | 333,480 |

All departments showed an improvement over the last quarter of 1913. Average price received for copper was 14.4117c., and the cost was 9.14c. per pound. Metal on hand and in transit, sold and unsold, amounts to 22,614,122 pounds.

YAVAPAI COUNTY

(Special Correspondence.)—Increased activity is being shown in the Mica district, which produces gold ore.

Skull Valley, May 14.

YUMA COUNTY

(Special Correspondence.)—A number of prospectors and miners from towns and mining camps have gone to the gold discovery at Mineral Hill, 20 miles east of Parker, made by E. Osborne. The formation is limestone and granite.

Parker, May 14.

CALIFORNIA

On completion of the work at the University of Idaho, about May 23, J. Boardman, first-aid miner, will leave his position with the U. S. Bureau of Mines car No. 5 and will proceed to California to give first-aid instruction in some of the mining camps which are remote from the railroads. Mr. Boardman will probably be sent first to the southern part of the state, where he will visit the following

mines: Tumco and American Girl near Yuma, Dale, and vicinity; Atolia, Randsburg, Skidoo, Tropico mine, and Mojave. He will probably be sent to the Mother Lode district, where he will visit the mines at Plymouth, Amador City, Sutter Creek, and Jackson, after which he will visit other districts where there are mines at some distance from railroads. He will make stops of from five days to two weeks at each group of mines, depending on the number of men employed. This work has been arranged in coöperation with the Industrial Accident Commission, which will pay Mr. Boardman's expenses in California. After car No. 5 completes the Nevada itinerary, it will probably proceed to California and visit the mines which are situated near the railroad. It will give training in the use of artificial breathing apparatus, as well as in first aid to the injured.

As a result of the work of Mr. Boardman and the mine rescue car of the Bureau of Mines, it is hoped to awaken interest in the work of first aid to the injured. Little attention has been paid to this matter in California mining districts in the past. If there are districts in which the services of Mr. Boardman are particularly desired, applications should be made to the Industrial Accident Commission to have him visit them.

ELDORADO COUNTY

There is little being done in the Georgetown district, but negotiations are under way for several properties, the Georgia Slide being one. The Eureka mine, at Cumming's station, has been sold to an English syndicate for \$30,000. It has produced a good deal of gold down to 750 feet.

MARIPOSA COUNTY

(Special Correspondence.)—The Bondi mine, 16 miles north and 4 miles west of Mariposa, and idle for over twenty years, is yielding some rich gold ore, according to Clinton I. Mentzer of Coulterville. There are a number of good mines in Mariposa county which were opened thirty or forty years ago, and with high transport and other expenses were shut down and have remained idle since. A state highway will pass through Mariposa soon, and the county supervisors are alive to the fact that the mining interest of the county demands good roads. The Number Five mine, of Hornitos, is under bond to S. W. Parker, of Berkeley, California. This property has an incline shaft 300 ft. deep, and a fair tonnage of low-grade ore is developed. The Mountain King mine, on the Merced river, is being actively worked under new management, a dam, ditch, and water-power plant are being constructed, and it is said that additional crushing machinery will be added in the near future. There are 30 men at work.

The Matone mine, on Buckingham mountain, is being opened by San Francisco parties.

The Sweetwater mine is being developed under the management of Mr. McAllister. This mine is equipped with 10-stamp mill, four concentrators, two tubular boilers, compressor, hoisting engine, and three machine-drills.

Mariposa, April 29.

NEVADA COUNTY

Foundations for 20 additional stamps are being prepared at the Empire mill, which will make a total of 60 head. Development at the Golden Center mine continues to be satisfactory. A 5-stamp mill is to be erected at the Premier mine, north of Grass Valley. The adit is in 1800 ft., showing a good tonnage of ore. The Narrow Gauge Railroad Co., operating between Grass Valley and Colfax, 17 miles, has paid a dividend of \$16 per share. The payroll in the Grass Valley-Nevada City district amounts to about \$100,000 per month.

PLACER COUNTY

The Gold Blossom mines at Ophir have been bonded to Charles Bugg, of Rochester, and other Nevada people for \$100,000.

SHASTA COUNTY

(Special Correspondence.)—The East Side copper belt is showing improvement, with several small companies at work. The Pit River Copper Co. was recently formed to develop a group of claims near Heroult, and has opened promising ore 70 ft. in from the adit portal. Fred Grotofend, of Redding, is manager. The Shasta Belmont company has completed its new wagon-road from the mine to Heroult, and has arranged to ship high-grade copper-zinc ore to Nevada smelters. A second vein, carrying large quantities of zinc and copper, was recently cut west of the main orebody. It is about 30 in. wide. W. E. Casson, of Carson City, Nevada, is president and manager. At both the Afterthought and Bully Hill smelters experiments continue to devise a satisfactory process for economical treatment of the zinc-copper ores. It is stated that the Afterthought people have devised a process, which will be employed, as soon as sufficient capital is available, to erect a new plant. The Shasta Copper

EMPIRE MINE, GRASS VALLEY.

Exploration Co. has arranged to establish a camp between Spring and Boulder creeks, near Kennett, and will vigorously prospect its extensive acreage. The Company controls 530 acres in addition to the large area recently bonded to the Mammoth Copper Co. San Francisco people are largely interested. Charles Wheelock is in charge of operations. M. E. Dittmar, of Redding, is consulting engineer. The new camp of the Mountain Copper Co., at Minnesota station, is rapidly taking shape. Several buildings have been completed and work on the main 200-ton concentrating plant will soon be well under way. The Mad Ox Mining Co. has been formed by Oakland and Seattle people to operate the Mad Ox mine near Stella. It is capitalized at \$115,000. Warren Beckwith is acting manager.

Redding, May 11.

A party of smeltermen visited Redding and Kennett on May 17 by invitation of the Mammoth Copper Co., the particular purpose of the visit being to view the experiments being made at the Holt & Gregg farm, near Anderson, by Richard Sprague, chemist for the Company. He is investigating the effect of acid fume on vegetation, and determining what damage, if any, is being done by any gases that may be in smelter smoke coming from the plant at Kennett.

An electric hoist has been installed in the Gladstone adit at French Gulch, 3700 ft. in, and at a depth of 700 ft. A shaft is now 1100 ft. below the adit and is to be sunk farther. Lessees have opened 4 ft. of \$20 ore in the American mine, adjoining the Gladstone.

SIERRA COUNTY

Work has been resumed at the Twenty-One mine at Alleghany, with 15 men. This property is on the Tightner contract between the Rainbow and Sixteen-to-One mines. F. M. Phelps is manager.

TRINITY COUNTY

The Asbestos claims, 22 miles northwest of Trinity Center, are to be developed this summer, in charge of C. Mecum. At the Bonanza King mine, Carrville, No. 4 adit is to be extended from 700 to 6500 ft., where it should cut the vein. George Foster is manager, and Thomas Grayner superintendent.

COLORADO

It is estimated that the output of radium-bearing ores from Colorado for the current year will total \$3,000,000.

TELLER COUNTY (CRIPPLE CREEK)

For the first quarter of 1914 the Doctor-Jack Pot Mining Co. shows that there are 13 sets of lessees working, and 1588 tons of \$14 ore was shipped. Development totaled 350 ft. on Company account at a cost of \$4.51 per foot. The cash on hand amounts to \$57,436. The Golden Cycle Mining Co. has already subscribed \$10,000 for the present extension of the Roosevelt tunnel, and has promised \$50,000 more for the extension from the Elkton shaft to the Golden Cycle shaft. On May 12 the Copeland Sampling Co. sampled 580 tons of ore in 570 minutes. Eleven 'clean-ups' were made during this shift.

THE SAN JUAN

The American Smelting & Refining Co. is starting the Silver Lake plant as a custom mill for the treatment of ores of the Silverton district, and is now ready to purchase and receive ores from anyone desiring to ship to this mill. An unloading station and sampler has been installed at the tracks of the Silverton Northern railroad, and all ore is sampled as unloaded, then trammed to the head bins of the mill. A satisfactory schedule has been prepared, and the ore is paid for as received and sampled. The Company then treats the ore and ships the concentrates, the lead going to the Company's smelter at Durango and the zinc to the smelter at Blende, near Pueblo. L. R. Clapp is manager.

IDAHO

SHOSHONE COUNTY

The Federal company's Frisco mine has been shut down, partly on account of the difficulty of treating the zinc-lead ore. The mill operated for about two months recently with varying success. The National Mining Co.'s new 500-ton mill, near Mullan, which began operations April 1, treated about 12,000 tons of ore in the first 30 days, or a daily average of 400 tons. The mill is now running three shifts, and it is expected that the maximum production will be reached by June 15. Metallurgical tests of the tailing show that the plant is saving 90% of the copper content, or 7% in excess of the original estimate. It was thought that only 20% of the copper could be saved by concentration, but the month's run shows 24 per cent.

The Montana-Idaho Copper Co., capitalized at \$600,000, has been organized by C. H. Gibbs, W. J. Kirby, and John L. Dirks, all of Spokane. The new Company has taken over the holdings of the Monitor Mining Co., comprising 125 acres of patented ground. It already had acquired a number of claims near the Monitor property, and has extensive water-power and dumping ground. Surveys have been established for a power-plant and plans are being prepared for a long lower adit that will develop the entire group to a vertical depth of not less than 1700 ft. The Marsh Mining Co. is to sell 165,712 shares of treasury stock at 25c. per share.

NEVADA

The itinerary of U. S. Bureau of Mines rescue car No. 5, in this state, is as follows: Copper Flat, near Ely, June 22 to 27; McGill, June 29 to July 3; joint Ely and McGill manoeuvres, July 4; Virginia City, July 6 to 11; Goldfield, July 13 to 18; Tonopah, July 20 to August 22. While the car is

at Tonopah, the crew will visit Manhattan, July 27 to August 1; Blair, August 3 to 8; Wonder, August 10 to 15; and Fairview, August 17 to 22. The car will then proceed to Reno and Sparks, August 24 to 29.

ELKO COUNTY

Good developments are being made in the Jarbidge district. The Elko Mining Co. has 18 ft. of \$20 ore at a depth of 420 ft. in No. 4 adit. Rich ore is being mined in No. 2 adit. A 5-stamp mill is at work. Four feet of \$30 ore has been opened on the surface of the Long Hikes claim. A 24-ft. vein is showing on the Pick & Shovel claim. A new vein is being driven on 60 ft. from the vein which has been developed to 300 ft. The latter is producing some rich ore. Prospecting is under way at the Jarbidge Gold, Arizona L's, Legitimates, Jarbidge-Altitudes, Coeur d'Alene-Jarbidge, and Ole Normal claims. The Beaver River Power Co. will supply electric power from either Malad or Buhl, in Idaho, this summer.

ESMERALDA COUNTY

At the Darms coal mine, at Coaldale, the incline shaft is down 326 ft., and is to be sunk deeper to prove the coal veins. H. E. Darms is manager.

HUMBOLDT COUNTY

(Special Correspondence.)—The suit of Samuel and Peter Stevens and I. P. George v. Jos. F. Nenzel has finally been settled, and the 210,000 shares of the Rochester Mines Co. involved has been distributed to the first-named interests. Shortly after having made the original find, Nenzel bought out the interests in the claims held by Samuel and Peter Stevens and I. P. George, and formed the Rochester Mines Co. Later, when the lessees on the main vein had proved the value of the property, those who had sold out instituted suit, which was tried in the federal court at Carson and has dragged along for about a year with the final result as stated above. While this suit has never involved the mines, being only a suit among various interests, it has tended to retard the development of the camp. It has long been predicted that, with the end of the litigation, a mill would be erected, and it is expected that such will prove to be the case. A large tonnage of mill-ore has been developed in the various leases.

It is expected to have the extension of the Nevada Short Line finished to Rochester and Nenzel Peak by August. A stock exchange has been organized here. Lessees at the Camelle Rock, Big Four, Codd, and Cole and Colligan claims are meeting with promising results.

In this camp driving or cross-cutting is no longer attempted with piston machine-drills, but is done with stopers and jackhamers. Progress has been found to be more rapid and the cost per foot of this work has been considerably reduced. While exact cost data are not available, it is significant that none of the lessees has used a piston drill for months past, and all adit work in the leases equipped with air has been accomplished with stopers and jackhamers in combination.

Rochester, May 5.

Placer work at the head of Limerick cañon, north of Rochester, is yielding about \$15 per day per man. So far the work is not extensive, but is rich. Primitive methods have to be employed, the gravel being either hauled to a spring a mile distant, or water hauled from the spring to the diggings. Quite a number of prospectors are in the field, some going into the east range.

At a meeting of the directors of the Rochester Mines Co. held at Lovelock on May 13, Wayne T. Wilson and E. B. Mills resigned, and were succeeded by W. C. Pitt and Samuel Platt. J. F. Nenzel resigned as president and general manager, and John F. Cowan was elected to his place. Plans are being prepared for a mill. Thus is settled the controversy that threatened to wreck the Company and stop the development of the camp of Rochester.

MINERAL COUNTY

The 100-ton copper-leaching plant is ready for work at the Wagner-Azurite mine, Luning. The process is that devised by John D. Fields.

LYON COUNTY

The Mason Valley Mines Co. reports as follows for the first quarter of 1914:

| | Mar. quarter, 1914. | Dec. quarter, 1913. | Mar. quarter, 1913. |
|---|---------------------|---------------------|---------------------|
| Mason Valley ore smelted, tons | 22,229 | 27,825 | 29,707 |
| Total ore smelted, tons..... | 45,008 | 50,197 | 70,709 |
| Copper produced, pounds.... | 2,742,032 | 3,694,227 | 4,611,881 |
| Net profit | \$9,128 | \$15,289 | \$73,517 |
| During the week ended May 13 the smelter received 3390 tons of ore. | | | |

NYE COUNTY

At Manhattan, lessees at the White Caps have removed the pumps and the mine was being flooded until the Company secured others. There has been friction among the board of directors.

The following April returns have been published from Tonopah mines: Belmont, 15,230 tons yielding 320,336 oz. bullion with a profit of \$150,494; Jim Butler, 3554 tons yielding a profit of \$36,727; North Star, which has cut 8 ft. of ore at 1130 ft., a profit of \$7000; and Tonopah Mining, 11,561 tons, producing 207,350 oz. bullion and 106 tons of concentrate worth \$35,000, the profit being \$103,100. A new tube-mill, Dorr classifier, and Trent agitator have increased the capacity of the Extension mill from 160 tons to 200 tons per day.

STOREY COUNTY

The 200-ton tailing plant of the Metals Recovery Co., east of Six-mile cañon, is nearly complete. It is estimated that there is 300,000 tons of old tailing to be treated which contains some copper.

WHITE PINE COUNTY

A suit for dissolution of the Consolidated Coppermines Co., of Ely, and the appointment of a receiver has been filed by Colonel Enos A. Wall, of Salt Lake City. He also asks for a return of his stock. There are 18 defendants in this suit. The Coppermines company has six churn-drills at work, boring 30 ft. each per day.

OKLAHOMA

TULSA COUNTY

During the current month the Tulsa Spelter Co. will start its plant at Sand Springs with 1600 retorts, there being 4000 retorts building in 1913, according to the U. S. Geological Survey.

OREGON

JACKSON COUNTY

(Special Correspondence.)—With only a few men employed, and a small mill working a few days each month, the Lucky Bart mine, in the Sardine Creek district, is doing well. The gold output in March was \$800, and the regular clean-up produced between \$700 and \$1000. The De Luse Mining & Dredging Co., of Sutherlin, has purchased the Lyman apple orchard, on the Rogue river near Gold Hill, for \$12,000. The area will be dredged, machinery having been ordered. The orchard yielded \$500 per acre last season, and the trees will be reset as soon as uprooted for the dredge. A. E. Bamber is to be in charge. Southern Oregon capital is to develop and equip the St. Albans copper-gold claims on the upper Applegate, in the Blue Ledge district. Henry Callahan and associates have been opening the property for some time past. A concentrating plant, to cost about \$25,000, will probably be erected.

Philomath, April 24.

(Special Correspondence.)—Kubli Bros., owners of the Gold Standard mine, of Galls creek, in the Gold Hill district, announce that this old property, which has been idle for the past seven years on account of litigation, will soon be reopened. About 2000 ft. of underground work has been done, and returns in the past have averaged as high as \$40 per ton. In a claim owned by Zeb Hyde, on the Applegate river, 12 in. of rich quartz ore has been opened.

Philomath, May 10.

UTAH

JUAB COUNTY

The Chief Consolidated, at Tintic, is shipping 3500 to 4000 tons of ore per month to smelters, and earnings are about \$14,000 per month. The present surplus is \$202,257. A new shoot of 15 to 20% copper ore has been opened at 2300 ft. in the Grand Central mine. Similar ore is also exposed at 2000, 2100, and 2200 ft. At the May Day mine, the cyanide plant is treating 2000 tons of ore per month. Lessees at this property have produced 21 cars of silver-lead ore.

SALT LAKE COUNTY

The Montana-Brigham tunnel is in 3000 ft., in softer ground than formerly. During the first quarter of 1914 the Utah-Apex company's gross receipts from lead ores were \$115,008, and net profit \$28,326. The mill was shut down in February and March for overhauling. There was a lower price for lead, which affected the revenue.

SUMMIT COUNTY

In April the Mines Operating Co.'s mill made a recovery of 82%, in treating 165 tons per day. A new roasting furnace is doing good work. The Nelson and Minola groups of claims of 150 acres have been merged by Park City people, and will be operated by the Three Kings Silver Mining Co. The ground is situated between the Silver King Coalition and Silver King Consolidated mines. The tailing problem in the Park City district is causing a good deal of discussion. Residue from the mills flows down Poison creek, and at one point covers the Union Pacific line. A conference between the railway and mining officials was recently held to deal with the trouble.

UTAH COUNTY

Ore is now being hauled from mines in the American Fork Cañon district, and there is a large tonnage awaiting shipment.

WASHINGTON

FERRY COUNTY

(Special Correspondence.)—Ore shipments from mines at Republic during the past two months were as follows:

| | March, tons. | April, tons. |
|-------------------------------|--------------|--------------|
| Ben Hur | 1870 | 3869 |
| Black Tail | 96 | 106 |
| Knob Hill | 605 | 1426 |
| Lone Pine | 41 | 25 |
| Rathfon Reduction Works | ... | 53 |

The destinations of these ores are to the San Poil mill at Republic, and smelters at Grand Forks, Greenwood, and Trail, in British Columbia.

Eight inches of shipping ore, assaying well in copper, has been opened in the Lakeside company's mine, north of Pierre lake, near Orient. The property is under bond to Dayton Stewart of Spokane.

KITITAS COUNTY

(Special Correspondence.)—The Bigney placer claim during a recent week produced \$234 with three men working. The largest nugget was worth \$23. This claim has done well this winter. The owner is now driving an adit to drain some ground ahead. Some time ago an attempt was made to drive down stream from this ground, and owing to the water, only 10 ft. was driven, but about \$300 in coarse gold was recovered.

so good results are expected from that area. J. E. and Charles Powles have recently sold two placer claims on Lyons gulch to William Brannan, of Cleveland, Washington. York and Siegel commenced hydraulic operations on Trilby gulch recently. The first clean-up netted them about two ounces. W. McCauley, owner of the Taft quartz mine, has arrived in camp and will soon start work at his property. Tom Livingston is opening up the Deer Gulch placer. This claim was one of the big producers some years ago, and is still considered valuable. E. M. Wells, who recently opened 'pay' on the Williams Creek placer, was compelled to shut down for a week owing to an accident to the hoist. E. Varden is contracting ore from the Whaleback claim. This claim contains some high-grade ore. From one month's run last fall, with an arrastre, Mr. Varden saved about \$800. The concentrate was run out with the tailing, as there was no way to save it.

Liberty, April 11

OKANOGAN COUNTY

(Special Correspondence.)—The Okanogan Free Gold mine and 10-stamp mill has been acquired by J. L. Harper of Republic. The weekly output is about \$1000 in bullion and concentrate. Probably 20 additional stamps will be installed. Rich ore has been discovered in the Recco mine, in the Myers Creek district, and prospectors are getting busy.

The Central Mining Co., in the Nespelem district, has opened 14 ft. of ore worth \$14.10 per ton in gold, silver, and copper, on the 100-ft. level. An adjoining property is yielding \$28 copper and \$2 silver ore. The Multnomah company has opened a good shoot of silver-lead ore. In the Double Header mine, 5 ft. of \$8 to \$22.50 gold-silver ore has been opened.

Oroville, April 21.

CANADA

BRITISH COLUMBIA

Fire at Stewart, in the Portland Canal district, recently destroyed a considerable quantity of property. The adit being driven by the Portland Canal Tunnels Co. was in 3050 ft. on April 11. Twenty-two miners are employed in charge of W. J. Elmendorf. Net earnings of the Standard Silver-Lead Mining Co. in 1913 were \$731,225, and after paying dividends the surplus was \$81,225.

Mining in the southern part of this province is more active this spring than for years past, according to Herbert Sharp, who has been 10 months in Nelson. All the mines around this place are being worked. Fatalities in mines of the province during the first quarter of 1914 total seven in collieries, and five in metal mines, against seven and three respectively in 1913, according to the chief inspector of mines, Thomas Graham. The Hedley company's power dam on the Similkameen river is practically finished.

Considerable attention is now being paid to the alluvial deposits of the Similkameen and Tulameen rivers in the southern part of this province, owing to the fact that the Tulameen district has the richest platinum deposits on the North American continent. C. E. Lee, of Seattle, Washington, is examining the claims of Coulthard and Snowden Bros. of Princeton. C. Lambert is to work his ground on Granite creek. An engineer of the Consolidated Mining & Smelting Co., of Trail, is examining the Union mine at Gloucester, and others in the North Fork district.

ONTARIO

During April, the Nipissing high and low-grade mills treated 170 and 6663 tons of ore respectively, and the refinery produced 550,150 fine oz. of silver. The yield was worth \$323,251 net. The new orebody has been developed for 540 ft. at No. 4 level. At 900 ft. the cross-cut is in 164 ft. and should cut the vein at 255 feet.

During April, the Dome mine produced 14,770 tons of ore yielding gold worth \$97,455. The annual meeting is to be held on May 26. During the financial year, 145,305 tons was treated, producing \$1,204,598 at a cost of \$919,512.

At the Tough-Oakes mine, No. 2 vein has been opened to 300 ft. depth, where it is 12 in. wide assaying \$79 gold per ton.

Two per cent nickel ore has been opened in Keewatin formation north of Sesekinika, near Swastika. During March the Buffalo mill treated 7015 tons of ore yielding 142,786 oz. silver. Dividend No. 59 was paid on April 1. During 1913 the Beaver Consolidated mine produced 25,256 tons of ore yielding 762,699 oz., valued at \$438,552.

YUKON

During the week ended May 2, the Canadian Klondyke Co.'s dredges produced 844 oz. gold. The first boat to reach Dawson this season arrived on May 18.

MEXICO

Cabled advice to the offices of the respective companies in London shows that mining has been suspended at the Buena Tierra in Chihuahua; the mills of the El Oro, Esperanza, and Mexico Mines of El Oro companies are shut down, but development is proceeding in charge of the Mexican staff; and at Pachuca the Santa Gertrudis mill is also not working, although the mine is being worked. The Buena Tierra ships its lead-

MAP OF MEXICO.

silver ore to the A. S. & R. smelter at Chihuahua, but this is out of commission, hence the shut-down.

SONORA

(Special Correspondence.)—The Pilares (de Nacozari) is owned by the Moctezuma Copper Co., but the Pilares (de Texas), 10 miles north of El Tigre, is the old Colonel Garcia silver property, confiscated and now worked by the Constitucionalistas. There has been a little excitement here lately, but the Mexicans have behaved well and no damage was done. The Pilares mine and Nacozari concentrator kept running as usual, also El Tigre mine and mill, entirely by the Mexican employees. El Tigre cyanide plant was shut down, as the chemicals were locked up. The Caridad was kept running and there was no trouble at all.

La Caridad, May 5.

The combined annual report of the Greene Consolidated Copper Co. and Cananea Consolidated Copper Co. shows a total revenue of \$7,436,390 and profit of \$2,180,260, which is only \$94,530 less than in 1912.

Exports from mines in this state through the 'port' of Agua Prieta in April were as follows: Moctezuma, 11,560 tons; El Tigre, 204; Calera, 36; El Temblor, 32; Estrella, 23; La Ventania, 23; San Ygnacio, 23; El Gallo, 34; Vacuero, 41; Cobre Verde, 5; El Globo, 59; Good Enough, 20; San Francisco, 10; Mexico, 31; Los Angeles, 21; Monte Cristo, 7; and Santa Rosa, 454; a total of 12,633 tons. El Tigre shipped 58 bars of bullion weighing 8475 lb., 55 sacks precipitate weighing 3970 lb., and 14 sacks sulphides weighing 900 lb. The total value of these exports was \$2,678,000.

Personal

C. S. HERZIG is in Norway.

WILLIAM C. WEISBROD is in New York.

A. W. ALLEN is at Cambridge, England.

JOSEPH STRUTHERS has returned to New York.

JULES LEBARTH was in San Francisco last week.

T. J. ANDERSON has returned to New York from Panama.

AUSTIN C. BRADY, of Guadalajara, Mexico, is in San Francisco.

E. A. STROUT has left Mexico and is now at Los Angeles, California.

E. A. WALLERS has been elected president of the Transvaal Chamber of Mines.

ARTHUR FEUST has returned from Nicaragua and is at 462 E. 138th street, New York City.

J. H. COLLIER has been appointed superintendent of the Montezuma Mining Company.

HOWLAND BANCROFT is back from Peru and is expected in Denver by the middle of May.

W. F. MACK has returned to Candor, North Carolina, from a visit to New York and Boston.

A. W. HOOKE, manager of the Forum River Co.'s property, has left England for northern Nigeria.

D. C. JACKLING was in San Francisco last week and is now in Nevada. GALEN L. STONE is accompanying him.

F. DANVERS POWER has returned to the University of Sydney, New South Wales, after a nine months tour of the world.

A. H. BOYD has severed his connections with the Denver Rock Drill Mfg. Co. His present address is 3700 Race street, Denver.

JOSEPH EMBLETON is now manager for the South Kalgurli mine, Kalgoorlie, in place of JOHN MORGAN, who resigned owing to ill health.

A. R. LEBLOUX sailed for Europe on May 15, as commissioner of the United States government and consulting engineer to the Bureau of Mines.

RALPH ARNOLD is to give a series of lectures at the Throop Polytechnic Institute, Pasadena, California, where a course on petroleum has been started.

ERROL MACBOYLE, field assistant for the California State Mining Bureau, is collecting data on the Grass Valley and Nevada City mining districts.

RICHARD HAMILTON, of the Great Boulder Proprietary, was elected president of the Chamber of Mines, Kalgoorlie, for the seventeenth time, on March 25.

JOHN M. BOUTWELL has finished a detailed geological survey of the Old Dominion property at Globe, Arizona, and has returned to his office at Santa Barbara.

C. W. PURINGTON has been appointed consulting engineer to the Lenskoi Gold Mining Co. of St. Petersburg, and technical adviser to the Lena Goldfields, Ltd., of London.

JAMES HEBBARD, manager for the Central mine (Sulphide Corporation), Broken Hill, New South Wales, is on a tour through Asia, England, Europe, and the United States.

T. A. RICKARD, representing the Royal School of Mines, of England, will speak on 'The Mining Engineer as a Pioneer,' at the Semi-Centennial celebration of the Columbia School of Mines.

K. M. SIMPSON has resigned as general manager for the Atlantic Mines Co. and Goldfield Merger Mines Co. ARTHUR I. D'ARCY will succeed him as general manager for the Atlanta Mines Company.

ELWOOD MEAD returned to Melbourne, Victoria, on May 12. Under the auspices of the Commonwealth Club of San Francisco, he gave an interesting hour's talk, May 8, on 'Land Settlement and Irrigation.'

J. TAFFANEL, mining engineer, former French inspector, and now the director of the French mine experiment station at

Lievin, is paying a visit to the United States, as a guest of the Bureau of Mines.

Operating officials of the Butte & Superior Copper Co. in Montana are as follows, according to the report for 1913: manager, J. L. BRUCE; mine superintendent, ANGUS McLEOD; mill superintendent, FRANK R. WICKS; and cashier, CHARLES BOCKING.

Among the refugees from Mexico who recently arrived in San Francisco are the following: J. C. ARCHIBOLD, Cinco Minas; R. A. CONRADS, Cinco Minas; W. F. HENDERSON, Amparo Mining Co.; C. F. JOYCE, Amparo Mining Co.; M. L. KAISER, Casados; Walter C. Minsch, Cinco Minas; S. H. PYLE, Amparo Mining Co.; and EDWARD THOMPSON, Espada Mines.

Operating officials of the Alaska-Gastineau Mining Co., controlled by the Alaska Gold Mines Co., are as follows: manager, B. L. THANE; assistant manager, J. R. WHIPPLE; superintendent of mines, G. T. JACKSON; chief engineer, H. L. WOLLENBERG; engineer for mill construction, C. E. BRUFF; and superintendent of the metallurgical department, E. V. DAVELER.

Obituary

J. C. HAVER, a well known geologist, died at Auburn, California, on May 15. He was a native of this state and was 60 years old. He leaves a widow, one son, and two married daughters.

JAKOB BOLIN, head of the physical education department of the University of Utah and one of the most widely known and popular men of that institution, died on May 15 after a short illness.

DUNCAN McMARTIN, a mine owner and a member of the Timmins-McMartin-Dunlap syndicate, which has figured so conspicuously in connection with the Cobalt and Porcupine camps of Ontario, died on May 2 at Toronto as the result of an attack of pneumonia. When Mr. La Rose, a French-Canadian blacksmith, discovered silver ore at Cobalt, he consulted the McMartin Bros., who were constructing a railway at that time, and formed a syndicate which led to the present La Rose Consolidated Co. When the Porcupine boom started they were early in the field, and acquired the Hollinger, Miller, Dixon, and other claims. Mr. McMartin had numerous interests, including the development of electrical power at Cobalt and Waiwaitan falls. He enjoyed great popularity among mining men, and was noted for his liberality, especially to those with whom he had been associated in his early days.

PAUL LOUIS TOUSSAINT HEROULT, whose name will ever be connected with aluminum and the electric furnace, died in Paris recently. Mr. Heroult pere was born at Thury-Harcourt, April 10, 1883, and received his early education in England and France. He later went to the Lyceum at Caen and to St. Barbe, Paris. In 1882 he attended the School of Mines in Paris, and the next year took his military service in the army. On finishing this he worked for a metallurgical firm, and giving his attention to aluminum, in 1886, two years thereafter, he obtained a patent for the production of this metal electrolytically. On his discoveries are based the improvements in methods that brought the price of the metal from \$20 a pound in 1884 to about 50 cents in 1901. The more recent achievements of Heroult have been in developing the electric furnace for steel, aluminum, and other metals. His principle here was the introduction of two electrodes into the melting-pot, so that the ore received the full effect of the heat and the furnace was little more than a container. A later improvement consisted of a third electrode, which was in the nature of a starter and which burned away when the furnace rose to its proper heat. For his furnace he received in January 1904 the medal of the French Society for the Encouragement of National Industries. The Heroult furnace is in extended use today in many places.

The Metal Markets

LOCAL METAL PRICES

San Francisco, May 21.

| | |
|--|------------|
| Antimony | 9 — 9½c |
| Electrolytic copper | 15½—15¾c |
| Pig lead | 4.15— 5.10 |
| Quicksilver (flask) | \$39.00 |
| Tin | 40½—42 c |
| Spelter | 6½— 6¾c |
| Zinc dust, 160 kg zinc-lined cases, 7½ to 8c. per pound. | |

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, May 21.—A good business is being done in copper, principally for domestic consumption. Copper shares are steady, but neglected; and a waiting policy reigns on Wall Street. Lead and spelter are firm, with practically no change. Business in London and Paris is dull. Metal quotations are: copper, £63 7s. 6d.; lead, £19; spelter, £21 7s. 6d.; and tin £149 per ton; bar silver cass at 26½d. (53c.) per ounce.

SILVER

Below are given the average New York quotations in cents per ounce, of fine silver.

Writing on April 30, Samuel Montagu & Co., London, discuss the silver position as follows: The fact is that demand is no longer the chief factor of the situation. For many years past the market has been wondering whence fresh demands could come sufficient to absorb supplies, visible or expected. The output had been on an increasing scale, the defunct Indian Specie Bank held a vast stock, financed by borrowed money, and an impression permeated quarters interested in silver that while these circumstances existed, no improvement in the price could take place. The problem faced now is of quite a different character. The Cobalt district in Canada appears to have reached the height of its production, and even betrays signs of retrogression. Owing to the trouble in Mexico, many of the important silver mines have been shut down, and whatever may be the outcome of this trouble, a stoppage more or less prolonged must take place in the contribution of Mexico to the world's available supply of silver. It will thus be seen that, contrary to the indications which have prevailed for many years past, any operator desirous of forming an opinion as to the future price of silver, needs to consider how long this shrinkage will continue, rather than what will be the extent of future demand. Demand is certain to arise in due course, and any competition, or continuity of purchases from a large buyer, such as the Indian Government, for instance, will find an all provided market from which to draw the desired supplies.

LEAD

Lead is quoted in cents per pound or dollars per hundred pounds, New York delivery.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

| Week ending | May 7..... |
|--------------|------------|
| Apr. 23..... | 38.50 |
| " 30..... | 39.00 |
| May 7..... | 39.00 |

METAL PRODUCTION OF THE BUTTE & SUPERIOR MINE

In 1913 the mill treated 296,940 tons of ore averaging as follows:

| | |
|------------------|-------|
| Gold, ounces | 0.021 |
| Silver, ounces | 10.59 |
| Copper, per cent | 0.22 |
| Lead, per cent | 1.169 |
| Zinc, per cent | 19.89 |

Zinc concentrate produced totaled 104,174 tons, containing:

| | |
|------------------|-------|
| Gold, ounces | 0.07 |
| Silver, ounces | 24.19 |
| Copper, per cent | 0.47 |
| Lead, per cent | 2.08 |
| Zinc, per cent | 49 |

About content of this concentrate was:

| | |
|----------------|-------------|
| Gold, ounces | 5,201 |
| Silver, ounces | 1,520,375 |
| Copper, pounds | 977,105 |
| Lead, pounds | 4,330,422 |
| Zinc, pounds | 102,102,568 |

There was also produced 2269 tons of lead concentrate containing 188 oz. gold, 98 oz. silver, 14,151 lb. copper, 1,788,465 lb. lead, and 895,048 lb. zinc. The gross value of the metal output was \$3,526,661. Spelter averaged 5.6c. per pound during the year, and costs were 4.45c. per pound.

Mineral Production of Peru in 1912

The following table is from *Boletin* 80 of the Cuerpo des Ingenieros de Minas del Peru:

| Productos. | Mineral. | Value. |
|------------------------------|-------------------|-------------|
| Carbón (coal) | tons 278,927 | Lp. 180,326 |
| Petroleo (oil) | tons 233,600 | 879,976 |
| Oro (gold) | kilograms 1,435 | 186,987 |
| Plata (silver) | kilograms 324,352 | 1,233,407 |
| Cobre (copper) | tons 26,970 | 1,867,855 |
| Plomo (lead) | tons 4,050 | 64,252 |
| Vanadio (vanadium) | tons 3,04½ | 150,000 |
| Bismuto (bismuth) | kilograms 51,038 | 14,155 |
| Tungsteno (tungsten) | tons 195 | 19,500 |
| Mercurio (quicksilver) | kilograms 400 | 104 |
| Borax | tons 1,674 | 15,096 |
| Sal (salt) | tons 23,292 | 16,305 |

Total value *Lp. 4,627,963

The output for 1912 showed an increase of Lp. 923,348 over that of 1911.

*1 Libra=\$4.8665 U. S. coinage.

THE department of mining engineering of the University of Illinois, the State Geological Survey, and the U. S. Bureau of Mines have coöperated during the past three years to study Illinois mining conditions. The information collected at 100 mines is published in district reports. In *Bulletin* 2, 'Coal Mining Practice in District VIII (Danville),' by S. O. Andros, are discussed causes of accidents to miners in Vermillion and Edgar counties; loss of natural resources by wasteful methods of blasting and mining; and the use of steel and concrete as substitutes for timber in the mines and other phases of underground work. The bulletin also contains a description of the methods of removing the overburden from a coal bed by steam-shovels, a system of mining which has been highly developed in this district. Copies of the bulletin may be obtained by addressing State Coal Mining Investigations, Urbana, Illinois.

THE total Panama canal excavation to April 1, 1914, was 219,618,104 cu. yd., leaving 12,734,986 cu. yd. remaining to be excavated under the revised estimate of July 1, 1913. Excavation for March was 1,226,644 cu. yd. as compared with 1,430,050 cu. yd. in February. The wet excavation amounted to 964,055 cu. yd., and dry excavation to 262,589 cubic yards.

GOLD PRODUCTION of Nova Scotia during the fiscal year ended September 30, 1913, amounted to 2365 oz. against 4385 in the previous year. The coal output was over 7,000,000 tons.

PIG IRON PRODUCTION in the United States in April totaled 2,269,955 tons, against 2,347,867 tons in March. There were 211 blast-furnaces in operation on May 1.

NITRATE OF SODA purchases from Chile by the United States in the fiscal year 1913 amounted to \$20,718,968, against \$15,431,892 in 1912.

THE AMERICAN METAL CO., LTD., has removed its offices in New York to 61 Broadway.

Company Reports

Y-WATER TIN COMPANY

This Company operates alluvial tin deposits at Emmaville, New South Wales. During the six months ended January 31, 1914, there was sluiced 235,000 cu. yd. of drift, yielding 154.5 tons of tin oxide, an average of 1.473 lb. per yard. The revenue was \$84,000; profit, \$29,000; surplus at credit of profit and loss account, \$53,000; and dividends, \$19,000. To date, a total of 2,485,000 cu. yd. has yielded 1369 tons of black tin.

GLOBE & PHOENIX GOLD MINING CO., LTD.

This Rhodesian company had another profitable year in 1913, the operating profit amounting to £355,592, against £351,634 in 1912. The mill treated 76,051 tons of ore yielding gold worth £500,971. The net profit was £299,072. Three dividends, totaling \$1.50 per share, were paid, and a balance of £51,985 was carried forward. Ore reserves contain 14,426 tons of \$110.50 ore, and total 180,757 tons averaging \$27.20 per ton. Developments were satisfactory, especially on No. 20 level north from No. 2 winze. During March of 1914, 71 ft. was driven on this level averaging \$134 per ton.

SONS OF GWALIA, LTD.

This is a Western Australian company, operating a large and profitable mine about 160 miles north of Kalgoorlie. Development in 1913 showed that reserves are about 625,000 tons of ore. The main ore-shoot is longer on No. 19 level than in those immediately above, and a winze has opened it to No. 20 level. The other shoot has not been found below No. 17 level, a geological examination showing an intrusion of country rock. The 50-stamp mill and cyanide plants treated 162,101 tons of ore yielding £269,792. The working profit was £66,277, out of which £66,300 was paid in dividends, the deficiency being drawn from £12,523 brought forward from 1912. The balance to 1914 was £12,501.

CIA. MINERA CHONTALPAN Y ANEXAS

This Company operates in the state of Guerrero, Mexico, and the report covers the year 1913. Exploration work totals 930 metres at a cost of \$35,138. The Modesto shaft was sunk to 140 metres, on No. 6 level, where prospecting is being done. Ore reserves in the mine and patio total 34,188 tons. The value of the reserves is estimated at more than \$1,000,000. High-grade ore was shipped during November and December. Five stamps have been in operation since July, and it is planned to increase this number to fifteen. New equipment cost \$36,387. While the Company has been molested by 'Zapateistas,' the losses due to them have been small.

Receipts from ore, concentrate, and silver, etc., were \$323,517, and profit \$168,195. Results of the past 8 months' operations have been satisfactory. The Company's balance in the bank, and in mineral pending liquidation, amounts to \$140,693 with ore reserves sufficient for four years.

BALAGHAT GOLD MINING COMPANY, LTD.

Balaghat is one of the Indian companies, operating at Kolar, state of Mysore. The report covers the past calendar year. The superintendent, Henry M. A. Cooke, states that at the end of the year there were 1538 employees, of whom 21 were Europeans. Mining was done to a depth of 3300 ft. Development totaled 5498 ft., with an average of 7.33 machine-drills per month. Ore reserves are estimated at 21,886 tons. A promising shoot was opened south on the 3175-ft. level. The 30-stamp mill crushed 42,700 tons of ore yielding 12,789 fine oz., with 81.14% recovery. The cyanide plant treated 38,436

tons of current and 57,816 tons of old tailing for 3075 fine oz., with 47.5 and 40.5% recovery respectively. The heads and tailing assayed \$1.60 and \$1.32, and 80c. and 32c. respectively. The gold realized £67,103, and £1,552,499 to date. The profit for 1913 was £2348. Cash assets over liabilities amount to £30,458.

EASTERN SMELTING COMPANY, LIMITED

The Company was registered July 20, 1911, to acquire as a going concern, from January 1, 1911, the business of a company of the same name, carrying on the work of smelting in Penang and elsewhere in the Federated Malay States. The undertaking comprises tin-smelting works and other property, also agencies at Knaba Sumpor, Seremban, and Sungei Besi. The year ended August 31, 1913, shows a profit of £25,693, which, together with £8217, the balance of the appropriation account remaining from last year, makes a total of £33,910. The interim dividend on the preferred ordinary shares absorbed £2500, and out of the balance of £25,745, £2500 was paid in respect of the final dividend on the preferred ordinary shares. Smelting operations were seriously affected by the retirement of the works manager, when reorganization was in progress. Although the balance of unappropriated profits, after the payment of the full preference dividend of 10%, will amount to £23,245, no dividend will be declared on the ordinary shares. Expenditure on a new plant, designed to secure a higher extraction of metal from the ores, is contemplated.

NORTH BUTTE MINING COMPANY

The report of the North Butte Mining Co. for the year ended December 31, 1913, contains the following information: The Granite Mountain shaft was sunk 779 ft. and stations were cut at 2200 and 2400 ft. Driving was done at 2000, 2200, 2400, and 2600 ft. on the Adirondack vein. On the first level mentioned, the east and west drifts have opened 235 and 300 ft. of ore 30 in. wide, assaying 8 and 7% copper, and 8 and 7 oz. silver per ton. At 2200 ft., the west drift has opened a further 90 ft. of ore, while at 2400 ft. this drift developed an additional 300 ft. of 4.5% copper ore, 10 ft. wide. The 2600-ft. level has not reached this large shoot yet, but the drift for 170 ft. has opened 3 ft. of 3.5% ore. Development on the Edith May, Jessie, South Gem, South Croesus, and Snowball veins was generally satisfactory. There was a fair amount of faulting at 2000 ft. on the last-named vein. Results were as follows:

| | |
|---------------------------------------|-------------|
| Employees | 880 |
| Ore sent to smelter, wet tons | 462,799 |
| Precipitate, wet tons | 71 |
| Copper, pounds | 28,318,321 |
| Silver, ounces | 1,602,163 |
| Gold, ounces | 1,567 |
| Revenue | \$5,182,674 |
| Net earnings | 1,437,777 |
| Dividends | \$20,000 |
| Surplus at end of 1913 | 3,418,556 |
| Cost per pound of copper, cents | 9.76 |

WHIM WELL COPPER MINES, LTD.

The Company operates a copper mine on Balla Balla creek, West Pilbarra district, Western Australia. During the year ended March 31, 1913, the ore produced was 17,123 tons, averaging about 8.5% copper. Of this amount, 3168 tons averaging 18% was shipped to England in bags by steamer, and 4682 tons of ore assaying 11.25% was exported in sailing vessels; the total ore shipments for the year being 7850 tons averaging 14%, worth about £80,708. The average price obtained was £73 8s. 9d. per ton of best selected copper. The gross tonnage of ore exported was lower than in the previous year, due largely to a hurricane in Febru-

ary 1912, which disorganized the shipping arrangements for some months. On March 31, 1913, the ore on dumps was 60,600 tons of 4.5%. There was developed and available in the mine about 100,000 tons of 5% ore, while the probable ore above water-level exceeds 1,000,000 tons of the same average. A Murex magnetic plant has been installed and is now in operation. The net profits for the year amounted to £20,175, which added to the last year's balance of £9714, after providing for the dividend of 5% paid July 8, 1912, and the mine manager's commission gave a total available balance of £29,889. Out of this the directors have written off £9761, leaving a net amount carried forward of £20,127.

IVANHOE GOLD CORPORATION, LIMITED.

On a capital of 200,000 shares of £5 each, this Kalgoorlie company has paid £3,250,000 in dividends to April, 1914, or £16 5s. per share. Since 1897 to the end of 1913, the year covered by this report, the output was 2,762,166 tons of ore yielding 1,757,883 fine oz. gold worth £7,494,844. The sum of £950,582 has been spent on mine development and equipment to date, of which the former accounted for £529,838. The Com-

VIEW OF SURFACE EQUIPMENT AT IVANHOE MINE.

pany has investments worth £184,203 in 44 different stocks scattered throughout the world.

During 1913, mine development amounted to 3728 ft., including sinking the main shaft 199 ft. to 2953 ft. Development cost 56c. per ton, according to the report of the general manager, R. B. Nicolson. A geological report on the East lode and the influence of a porphyry dike between 3028 and 3200 ft. depth, will be published in another issue of this journal. Ore reserves in four lodes total 991,417 tons averaging \$9.24 per ton, of which 738,365 tons are in the East lode. The estimates show a decrease of 89,433 tons and 50c. per ton compared with 1912. Mining costs were \$3.61 per ton.

The 100-stamp mill, sand leaching, slime filter-pressing, and concentrate plant treated 239,314 tons of ore, 104,292 tons of sand, 111,563 tons of slime, and 23,459 tons of concentrate, yielding 106,683 oz. gold and 22,071 oz. silver worth £455,519. The recovery was 88.77% at a cost of \$2.16 per ton. Filter-pressing costs were 14c. per ton of ore treated.

ANACONDA COPPER MINING COMPANY

The holdings of this great Company in Montana are too well known to require much comment, and results for 1913 are best tabulated as follows:

| | |
|--|-------------|
| Development in all mines, miles | 35.3 |
| Ore mined, tons | 4,644,201 |
| Ore treated in Washoe plant, tons | 4,016,689 |
| Ore treated in Great Falls plant, tons | 1,170,150 |
| Custom ore included in the above, tons | 619,864 |
| Precipitates, etc., smelted, tons | 7,767 |
| Metal production from all ores: | |
| Copper pounds (Company's share, 241,983,323) .. | 270,301,644 |
| Gold, ounces (Company's share, 64,898) | 64,898 |
| Silver, ounces (Company's share, 8,719,132) | 10,321,296 |

| | |
|---|---------------|
| Coal mined at Belt and Washoe, Montana; Diamondville, Wyoming, tons | 736,231 |
| Sawmill output, board feet | 87,780,763 |
| Lumber purchased, board feet | 49,934,678 |
| Lumber sold, board feet | 63,515,212 |
| Butte, Anaconda & Pacific Railway operation: | |
| Ore carried, tons | 5,842,944 |
| Passengers | 304,138 |
| Net income | \$232,421 |
| Financial: | |
| Revenue from copper, gold, and silver | \$ 44,003,473 |
| Metals on hand at end of 1913 | 16,173,788 |
| Other revenue | 1,084,494 |

| | |
|--|---------------|
| Total revenue | \$ 61,258,755 |
| Revenue in 1912 | \$ 67,262,041 |
| Metals on hand at beginning of 1913 | \$ 14,895,384 |
| Mining expenses | 18,457,559 |
| Treatment expenses | 8,709,588 |
| Depreciation (\$727,350) and other expenses | 4,470,276 |
| Balance for dividends | \$ 11,323,498 |
| Dividends paid | 12,997,500 |
| Deficit | 1,674,002 |
| Previous surplus | 8,695,172 |
| Final surplus | 7,021,170 |
| Net assets | \$108,312,500 |

The reduction in output was due to bad weather in January and February, and a stoppage of 11 days to clean out the main flue of the Washoe plant. Development generally in the mines was satisfactory. There was a marked improvement on the 2400-ft. level of the Anaconda, and a large vein was opened to 3000 ft. in the Original mine.

COPPER RANGE CONSOLIDATED COMPANY.

This Michigan company controls the Baltic, Champion, and Trimountain mines, and the report is for the year ended December 31, 1913. Like all other properties in the Houghton district, the strike of last July affected operations considerably. Results from individual mines are as follows:

| | Baltic. | Champion. | Tri-mountain. |
|--------------------------------|-------------|-------------|---------------|
| 'Rock' stamped, tons | 333,289 | 421,849 | 229,149 |
| 'Mineral' produced, pounds .. | 13,282,825 | 19,251,470 | 8,546,070 |
| Refined copper, pounds | 7,736,124 | 12,080,594 | 4,990,938 |
| Revenue from copper, etc. | \$1,152,026 | \$1,802,530 | \$746,529 |
| Total profit | 230,211 | 504,767 | 113,363 |
| Dividends | 200,000 | 900,000 | 200,000 |
| Surplus at end of 1913 | \$336,317 | \$548,643 | \$444,757 |
| Cost per pound of copper, | | | |
| cents | 11.91 | 10.71 | 12.62 |

The Copper Range railroad had a revenue of \$575,065, and after paying expenses, taxes, bond interest, etc., there was a deficit of \$17,046, but the final surplus for the year amounted to \$425,781, there being \$465,548 brought forward from 1912.

The Copper Range Consolidated report is summarized as follows:

| | 1913. | 1912. |
|-------------------------------|-------------|-------------|
| 'Rock' stamped, tons | 984,287 | 1,784,402 |
| Copper produced, pounds | 24,852,026 | 37,584,647 |
| Total revenue | \$3,707,091 | \$6,084,202 |
| Net income | 490,533 | 1,692,566 |
| Dividends paid | 1,084,498 | 788,428 |
| Deficit | 593,965 | |
| Surplus | | 904,138 |

The decreased results were due to the strike mentioned, and the lower price received for copper, namely 14.89 and 16.16c. per pound for 1913 and 1912. Development totaled 19,489 ft. in all the mines. New drilling machines were installed with satisfactory results. Work on the new power and regrinding equipment was continued, costing \$230,835 and \$290,000 to the end of 1913.

SALT CREEK OIL FIELDS, NATRONA COUNTY. By L. W. Trumbull. Bulletin 8. P. 46. Maps. This is an important oil district, there being 19 operating companies. Casper is the centre for the area.

GEOLOGY OF THE AROHA SUBDIVISION, HAURAKI, AUCKLAND. By J. Henderson and J. A. Bartrum. Bulletin 16. P. 127. Ill., maps, charts, index. Geological Survey, Wellington, New Zealand, 1913. The area described contains about 662 square miles, of which 250 square miles is hilly. The mineral wealth is considerable, Karangahake being the active centre. A large quantity of timber is being cut. The principal wealth of the district is in its wide pasture lands. The rainfall varies from 55.75 to 83.06 inches in different parts, and the temperature averages 58.4° F. To the end of 1911 mines at Karangahake had produced bullion worth £2,594,822 from 890,809 tons of ore. Those at Te Aroha had yielded £116,646 from 55,572 tons. The highest peak is 3126 ft. above sea-level, and a prominent point at Karangahake is 1775 ft. high. There are several large rivers flowing through the subdivision. Rocks are andesite, dacite, and rhyolite, and quartz forms the principal gangue of the ores. Lodes have been faulted in many places, and decrease in number and size with depth.

Decisions Relating to Mining

CANCELLATION OF PATENTS—NO DISCOVERY

In a suit brought by the federal government to set aside certain placer patents of land adjoining the junction of the Nispelem and Columbia rivers, it was held that evidence showing that the only discovery of gold ever made on the lands had been merely a few fine traces such as occur all along the Columbia river, and that the real economic value of the lands in question lay in their power-site possibilities, was sufficient to justify a decree canceling the patents to the same as having been obtained through misrepresentation and fraud.

Multonomah M. M. & D. Co. v. United States (Washington) 211 Federal, 100. January 5, 1914.

CONDEMNATION FOR MINING PURPOSES

The Goldfield Consolidated Milling & Transportation Co. has been awarded a condemnation decree by the Nevada District Court, entitling it to take the title in fee to the surface of certain adjacent claims owned by the Old Sandstorm Annex Gold Mining Co. and others, for the purpose of storing and treating tailings from the plaintiff's mill. Storage and treatment of tailing was held to be a 'mining purpose' which constitutes a public use under the laws of Nevada. Held also that merely the surface of said lands could be taken and paid for under such proceedings as distinct from the sub-surface mineral rights.

Goldfield Con. Milling & Transportation Co. v. Old Sandstorm Annex Gold Mining Co. (unreported). District Court of Nevada (Esmeralda county), March 16, 1914.

LODE LOCATIONS—VOID AS TO EXCESS—LIMITATIONS

An interesting decision has just been rendered by Judge Farrington, sitting in the United States District Court of Nevada, in the controversy which arose out of conflicting locations in Copper cañon, Lander county, Nevada. The liquidators of the Glasgow & Western Exploration Co., who were complainants in the quiet title suit, relied upon lode locations covering the ground in controversy designated as the Salt Lake No. 3, Evening Star, and Midas lode claims. Six years subsequent to the date of the last lode location the defendants who were prospectors covered the identical ground with placer locations. Suit was brought by the owners of the lode claims to quiet title, and the defendants set up a defense that the west side lines of the lode claims were more than three hundred feet from the centre line of the vein. This fact was not substantially controverted, but the lode owners claimed that the statute of limitations barred the defense. There was also a dispute as to the validity of the lode discovery, although the court held that a preponderance of the evidence sustained the complainant's claim. The rulings of law were as follows:

1. It has never been held that in order to constitute a valid location commercial ore must be discovered; a discovery of mineral rock in placer is sufficient.

2. The lode claims were void as to the excess over 300 ft. on the west side of the centre line of the vein. The excess amounting to as much as 200 ft. in some placers, there could be no question of a bona fide mistake in determining the position of the apex such as induced the court to allow the excess in the case of *Harper v. Hill*, 113 Pacific, 163.

3. The statute of limitations did not apply as to the excess. Decrees were ordered in accordance with the foregoing opinion. It is probable that an appeal will be taken.

Lamont v. Davis et al.—cases A-19 and A-20, U. S. District Court for Nevada.

Industrial Progress

New Ore Feeder

The Denver Engineering Works Co., which supplies the material for the following description, is selling a new ore feeder of the 'Monkey Wrench' type illustrated in the accompanying figures. This feeder retains the revolving disk and stationary plows of the well known Challenge type, but the number of parts is greatly reduced and the wearing parts are such that they can be made by any good blacksmith. There are no gears, cams, clutches, pawls and ratchets, shoes, deli-

FRONT VIEW OF FEEDER.

cate springs, or other such troublesome parts. Each piece of the actuating mechanism is of most rugged construction and only one heavy spring is used. The monkey-wrench type of grip gets its name from its similarity to the monkey wrench when applied to the rim of a pulley for the purpose of forcibly moving it. This grip, applied on the edge of a secondary disk below the main disk of the feeder, is shaped like the open jaws of a monkey wrench. When pushed in one direction by the action of the falling tappet the jaws clamp on the disk

BACK VIEW OF FEEDER.

and carry it around. When pushed in the opposite direction by the spring, the jaws slide along the edge of the disk instead of clamping and are then in position for the next movement to carry the disk around again.

The tappet arm, shaft, and depending lever which actuate the grip are forged from one piece of carbon steel. The shaft

is carried in two bearings with adjustable caps. The hand screw adjusting the range of grip movement has a heavy four-winged check nut which may be set with a hammer. The feeder disk has a renewable steel wearing plate and the feeder disk shaft is adjustable vertically by a set-screw at its lower end. The gate is adjustable in the usual manner. The feeder hopper is open at the back with bolt or rivet holes suitably placed along the edges for connecting to the sheet steel or wooden chute from the ore-bin. The shipping weight is 1050 lb. and the heaviest single piece weighs 200 pounds.

The announcement is made that the United States Steel Corporation and its subsidiary companies propose to have a comprehensive exhibit of its operations at the Panama-Pacific Exposition in San Francisco in the year 1915. It will begin with mining and include rail and water transportation, dock operations, coal, coke, and pig iron production, and steel manufacturing in its various lines. It will also present the processes of manufacturing of many of its subsidiary companies' products (such as the National Tube Company), also the many by-products. There will be displayed the uses in which its general products are employed, typifying the advancement in the uses of this country's resources. In addition to the material exhibits the Corporation intends to exhibit in a comprehensive manner, by moving pictures, its operations throughout all departments showing the ramifications of the processes of the corporation's operations. It is also proposed to set forth to the world the work which the United States Steel Corporation has done toward the social welfare of its employees and those depending upon them. Also it will exhibit many forms of safety devices that have been conceived by the corporation officials and its employees.

At the annual meeting of the stockholders of the JOSEPH DIXON CRUCIBLE Co., held at Jersey City, N. J., on Monday, April 20, 1914, the retiring board of directors, consisting of Geo. T. Smith, William Murray, George E. Long, Edward L. Young, William G. Bumsted, J. H. Schermerhorn, and Harry Dailey, were unanimously re-elected. The meeting was attended by a large number of stockholders who expressed satisfaction with the present management and recorded the largest vote ever represented at an annual election, 9628 out of a possible 10,000 shares being represented. The officers of the Company were also re-elected.

The DODGE MANUFACTURING Co. has opened southwestern sales and engineering offices at Dallas, Texas, and a sales and engineering office at Grand Rapids, Michigan. J. H. Drapier of the general sales department, Mishawaka, has been made manager of the Dallas office, and Oscar W. Gregg, late of the Gilbert Pulley Co., representative at Grand Rapids. A short time ago the Company opened an office at Indianapolis in charge of E. M. Carver.

'Mine and Quarry' for April, issued by SULLIVAN MACHINERY Co., is at hand, and as usual is replete with interesting matter. The drill boat *Burrard*, now in use at Vancouver harbor. B. C., is described.

'Leschen's Hercules' for May, issued by A. LESCHEN & SONS ROPE Co., St. Louis, Missouri, has for its leading article a description of a method of handling stone in a quarry by wire rope.

WM. POWELL Co. is distributing a circular on the new Powell extra heavy iron body, straightway 'Y' blow-off valve, and a booklet describing the Powell Union composite disc valve.

ELSPASS ENGINEERING & MINING MACHINERY Co., Denver, has issued a catalogue on the New Principle Chilean mill.

CHICAGO PNEUMATIC TOOL Co.'s Bulletin No. 172 gives details concerning the No. 5 Chicago Plug and Feather drill.

EDITORIAL

A ZOLOTNIK per cubic sagene does not mean much to the average English-speaking engineer. We are, therefore, glad to present in the current issue a translation from the Russian by Mr. William H. Shockley of the gold and platinum dredging production of Russia for 1912.

NATOMAS CONSOLIDATED report for 1913 shows the working profit from dredging operations alone to have been \$992,366. The interest on bonds and miscellaneous losses, however, make the actual profit to the Company only \$107,840. The dredging profit for the year was previously estimated at \$1,350,000, and that it did not reach this amount was largely the result of high cost of production, this cost increasing from 4.463 cents in 1912, to 5.354 cents in 1913. In that negotiations are pending for re-financing Natomas, the report is of special interest at this time.

COMMITTEE ON MINES AND MINING of the House of Representatives has recently reported favorably upon a general bill for the establishment of ten mining experiment stations and fifteen mine safety stations. The bill has the hearty support of the Bureau of Mines, and it is believed that it will become a law by the first of next year. In a report on the bill by chairman of the Committee on Mines and Mining of the House of Representatives, it is stated that Congress is now appropriating \$28,000,000 annually for agricultural advancement, and that while the conditions underlying agricultural progress differ as to many details from those associated with mining, the broad general principles of progress are the same. The favorable response to the national aid for agriculture is itself an evidence of the result which can be depended upon if similar aid is extended to mining.

NEW MINING REGULATIONS of China present many interesting features, chief among which may be mentioned the provision which permits foreigners to hold one-half the total number of shares in a mining company. With characteristic Chinese indirection, the Minister of Industry has publicly stated that foreigners may provide whatever portion of the capital is necessary if the Chinese fail to subscribe their part. This would provide for the control of mining companies by the foreign interests, which is a pre-

requisite to securing foreign investment in Chinese mines. The great difficulty in the development of Chinese mines has been the bad administration of the Chinese in control, and it is only by foreign methods of business administration that mining enterprises can be successful in China. With the present personnel of the Ministry of Commerce and Industry and the Mining Bureau, it is scarcely probable that foreign companies will invest money in enterprises which are to be strictly supervised and regulated by these officials.

MOORE FILTER COMPANY of New York has commenced suit in the United States District Court of Delaware against the Tonopah Mining Company of Nevada and the Montana Tonopah Mines Company for an injunction restraining these Companies from using the Butters filter process and also for an accounting of damages. This suit comes as a sequel to that brought against the Tonopah-Belmont Company for an infringement of the patent rights in respect to the same filter process and was decided against the Belmont company in the U. S. Court of Appeals in November 1912. Since this decision this Company, together with the Tonopah Mining Company, Tonopah Extension, West End, Mac-Namara, and the Montana Tonopah have modified and are changing the filter processes used in order to avoid all possibility of future litigation. In that changes have been made in the filter processes used, it is believed at Tonopah that the granting of injunctions will not interfere with the operation of the mills involved. When the mining laws have been revised and disposed of by Congress in a manner which will reduce the number of legal entanglements, it would seem that a revision of the patent laws and methods would be in order.

OUR attention has been called to an error in the article on 'Tin Mining in Bolivia,' written by Mr. G. W. Wepfer and printed by us February 7. In it the Compañía Estañífera de Llallagua is credited with an annual production that in fact about equals the present monthly output. In 1913 this Company produced 114,938 quintals of 65 per cent tin concentrate. In March 1914 the output was 12,000 quintals, and it is expected that by the end of the year 15,000 quintals will be produced per month. This makes the mine one of the most important tin-lode mines in the world. The value of the annual output is approximately \$3,000,000, and it is a matter of pride that the excellent technical work being accomplished is under men educated in the United States. In addition to the two large veins mentioned by Mr. Wepfer, others, some of which do not outcrop, are now mined, so that in all there are workings on 14 veins. The same veins are worked by the Compañía de Uncia of St. Simón I. Patiño and there is now threat of litigation over the ownership of certain of the orebodies. We are also informed that there is now no agreement with the Bank of England as to exchange on Bolivianos.

Bering River Coal

The report of the Bureau of Mines on the coal resources of Alaska and their possible use by the United States Navy has recently been referred to the Committee on Naval Affairs by the Secretary of the Navy. While the report is of a negative nature as to the use of this coal by the Navy, the thoroughness of the work is to be commended and the results obtained are invaluable as a compendium of information on the fuel value of the visible Alaska coal measures.

The requirements of navy coal, as specified to the examining engineers and geologists, were that the coal should have a fair proportion of lump, free from slate, and low in sulphur; with volatile matter not lower than 12 nor higher than 22 per cent, and preferably between 14 and 18 per cent; with not more than 8 per cent ash and with high fixed carbon and heating value of above 14,000 B.t.u. After preliminary explorations, the engineers in charge agreed that the most likely deposits were those on Trout creek, Carbon creek, and the east slope of Kushtaka ridge, of which that on Trout creek, known as the Tenino claim of the Cunningham group, was selected as being the most promising. From the three most promising beds, 850 tons was mined, sacked, and subsequently transported to tidewater, and placed on board the U. S. S. *Maryland*. Fifty tons was reserved for shipment to the engineering experiment station at Annapolis, while the balance was consumed in steaming tests on board the *Maryland*.

The coal was tested in comparison with Pocahontas coal and resulted in the conclusion that full speed cannot be maintained with Bering river coal; the quantity of ash and clinker produced, and constant clinking, throws such excess work upon the men as to make impossible even moderate speed except for a short period; the coal, however, is far superior to Pocahontas in smokeless qualities, but cannot compare with Pocahontas in efficiency. It is therefore recommended that Bering river run-of-mine coal is unsuitable for use with forced draft in naval boilers.

The coal tested at the engineering experiment station of the Naval Academy at Annapolis was screened and washed to represent the best grade that can be expected from the Bering River fields. This reduced the ash content from 14.06 per cent to 5.42 in the dry coal, causing a loss of 48.59 per cent of the fuel as mined. The evaporation was 5.04 pounds of water from and at 212°F. per square foot of water heating surface, and a combustion of 19.11 pounds of dry coal per square foot of grate surface per hour. The cost of preparation on a large scale would be \$6.34 per ton of cleaned coal. These results show even the cleaned coal to be of inferior grade and unable to compete with Eastern bituminous coals when shipped to the west coast. It is therefore to be concluded that the Bering river coal is unavailable as a source of coal for the Navy until extensive general development shall find a coal not possessing the serious objections

found in the samples tested by the department. While the result of the investigation has shown the visible coal to be unsuited for use in the Navy, it is not unlikely that future exploration will reveal deposits which will be available for this use and also that the coal in sight will find a commercial use in the industries of the future.

Radium

Radium has within the past year been the subject of a great deal of comment and the amount of mis-information regarding the nature and therapeutic value of this element is far in excess of what has actually been proved regarding it. The medical fraternity is hopeful that radium salts will be demonstrated to be beneficial if not a cure for certain malignant growths; but the real value in this respect has by no means been determined. The proposed radium bill, discussed in our issue of April 11, now appears to be doomed, and interest taken by the Government toward the conservation and investigation of this element have tended toward an exaggerated publicity of all phases of the subject. The nature and origin of the element is exceedingly hazy in the minds of most people and we are therefore glad to publish an article by Mr. C. T. Kennan on 'Radium and its Sources' in this issue.

Radio-activity belongs to the field of higher physics and physical chemistry and it is, therefore, difficult for one wholly unfamiliar with these subjects to understand the rudiments of radium-therapy. The subject dates back to 1901, but is still in its infancy and those interested will find 'Radium-therapy' by L. Wiekham and P. Degrais, translated by S. Dore, to be both interesting and instructive. Although our present knowledge of its physiological action is extremely limited, it is believed by many who have made a special study of the element to be the most valuable agent that we possess. Harvard University is at present conducting an investigation of the radium therapy, and while a very conservative view is being taken by the commission of this University, it is planned to pursue the investigation indefinitely with the hope of eventually determining just what radium and its derivatives can do.

The radio-activity, to which the element owes its value, is a property possessed by some forms of matter, which is due to a process of spontaneous atomic disintegration. Most forms of radio-active matter are characterized by the sending out of rays, which are of three types. The alpha rays are easily absorbed and are positively charged with helium atoms which are emanated from the disintegrating atoms with great velocity. The beta rays are more penetrating and consist of negative electrons (particles 1700 times smaller in mass than the hydrogen atoms) and move with a velocity about that of light; and the gamma rays, whose emanation is a very penetrating form of radiation analogous to the Röntgen rays. The final radio-active forms of matter resulting from the decay products of the uranium, actinium, and thorium series are not definitely

known, although, according to Mr. C. H. Viol, lead would seem to be the end product in the uranium-radium series and bismuth has been suggested as the end product in the thorium series.

The measurement of radio-activity may be made in several ways, as the effect of the rays on a covered photographic plate, the measurement of the heat emission, by counting the alpha rays while observing the scintillations which these rays produce when they impinge upon willemite, or diamond screens. Electric methods, however, such as the electroscope are usually employed for this purpose. When a radium salt has been kept sealed for a month, the maximum amount of emanation and active deposit has been accumulated and the gamma ray activity, which is the ray of therapeutic value, reaches a maximum. The rate of decline of the radio-activity is almost unappreciable and the radio-active life of the element has been estimated at 4000 years. Until recently a milligram of pure radium bromide, which contains 53.6 per cent radium element, has been the standard of measurement for radium salts. The Committee for an International Radium Standard has defined the 'curie' as the quantity of radium emanation in equilibrium with one gram of radium element, which standard has met the approval of the scientific world and is now accepted.

Only those minerals and ores which contain uranium contain radium, and these ores are found in commercial quantities in the United States in Utah and southwestern Colorado. The great part of this ore is the brilliant yellow uranium mineral, carnotite. But little pitchblende is produced in this country, the sole output being from Gilpin county, Colorado. The world's annual production of radium was estimated a short time ago at nine grams, about one-third of an ounce, and of this amount six grams are produced by the Standard Chemical Company of Pittsburgh. With recent enlargements of the laboratories of this Company and scope of operations it is expected materially to increase this output. The question arises, however, as to whether the mines will be able to deliver to Mr. Flannery and his associates, a continuous supply of carnotite to produce such an output. In that the percentage of radium in the ore mined is about that of gold in sea-water the reduction presents interesting problems, which the Bureau of Mines is now investigating. The work of the 'radium trust' is being largely conducted behind locked doors at present and no information as to the concentration and refining is available from this source. The work of the Bureau toward disseminating knowledge and information on this subject is most commendable and whether the Government does or does not exercise the control over the output of radium ore in this country, the Bureau of Mines investigation is producing results and we trust that the work along this line will be continued on a still larger scale in the future. Radium is at least worth investigating in the interest of humanity, and if results are near what is anticipated by many, a great good will be effected.

New World Mining District

By E. D. GARDNER

The New World, or, as more commonly called, the Cooke City mining district, is situated in Park county, Montana, in unsurveyed townships 14 and 15 east, range 9 south, at the headwaters of the Stillwater and the Clark's Fork of the Yellowstone rivers. It adjoins the northeast corner of the Yellowstone National Park, and is in the Beartooth National Forest. Min-

SOUTHWEST MONTANA, SHOWING POSITION OF NEW WORLD DISTRICT.

eral has been found in an area about eight miles north and south by six miles east and west.

Cooke City, the only settlement, is in the southern part of the district, and is reached by a wagon road from the Northern Pacific railway at Gardiner, Montana, about 65 miles distant. Approximately 62 miles of this road is within the Yellowstone National Park and was built and is still kept in repair by the federal government. The road is splendidly laid out and constructed, the grades being easy, and the streams well bridged. The first 25 miles, or so, of the road, which is a part of the general park tourist route, is very well kept up, but the other end has been allowed to get in a bad state of disrepair. It is, however, far better than most mountain roads of similar character. In the summer time the stage easily makes the trip to Cooke City from Gardiner in 12 or 13 hours.

The elevation of the New World mining district ranges from 7500 and 7700 ft. above sea-level at Cooke City to 12,000 ft. at the top of some of the peaks. The rocks in the lower levels of the cañons are generally concealed from observation by a mantle of boulders and soil. The rocks at the higher elevations on the mountainside are well exposed, and in many places outcrop in bold cliffs. The whole country has been glaciated, and there are evidences of terminal moraines throughout the region. On the sides of the higher peaks the moraines are comparatively recent and consist mainly of huge boulders. There are several live glaciers now in the district, one of which, notably the Grasshopper, has more than local interest. This glacier, which is about one mile long and one-half mile wide, has proved mainly of interest from the fact that many grasshoppers are found embedded in the ice.

A large number of mineral prospects have been located above timber line in this region. In an effort to develop the mineral outcroppings beneath the surface, adits, whose portals are in banks of perpetual snow, have been driven into the sides of the mountains. Lands lying below an elevation of 8300 or 8400 ft. for the most part support a stand of merchantable timber. According to estimates recently made by the National Forest Service, there are twenty-five to thirty million feet of saw timber available for the needs of the mining industry, consisting of Engelmann spruce and Douglas fir. In addition to this, there is a large amount of lodgepole pine suitable only for stulls or fuel.

The summer season is short and very pleasant, although water may freeze any night. The winter snows are very heavy, and in ordinary years lie to a depth of about 6 ft. on the level in Cooke City, and deeper as the elevation increases. The only means of travel in the winter is on snow shoes, except on the public road leading to Gardiner, which is kept in passable condition by the mail stage. Snow falls in early October and lies on the ground well into May. In the spring break-up, during the last of May, the district is practically isolated for a couple of weeks. The only means of communication with the outer world during this period is through the Forest Service telephone line and a dogsled which brings in the mail. Trails and wagon roads from Cooke City lead to the outlying mines or prospects, and all parts of the district are fairly accessible.

Cooke City District

The region about Cooke City is one of the most rugged and picturesque in the United States, and its scenic beauty is rivaled in but few places. The innumerable mountain lakes, gorges, waterfalls, and other works of nature, are well worth further notice. Eastward from the confines of the mining district there is a vast country of which little is known, and which has even greater scenic beauty. But few men have overcome the barriers and withstood the hardships necessary to penetrate this region. These returning prospectors and explorers report an absence of large mineral showings, and tell of a wilderness of high mountain peaks, mountain gorges, ice fields, wonderful ice caves, forests, and many other interesting features. The hunting and fishing in the entire region is good, and, in the event of a railroad being built into the district, it will be justly famous as a summer resort.

Horn Miller, Pike Moore, and Pat O'Hara, trappers and prospectors, in the year 1871 explored the country in and adjacent to what is now the New World mining district, which was then in the Crow Indian Reservation. In some of the gulches, near what is now Cooke City, they found evidence of placer gold and staked

out and worked, in a small way, several claims. One of the first locations is still being worked by Horn Miller, although the production of placer gold in the camp has never been important. The discovery of gold, as a matter of course, brought in more men, and it was but a short time until lead-silver, gold, and copper deposits were discovered in the mountains. The high cost of getting ore to the railroad has seriously retarded the development of the district from the beginning. The miners have been periodically encouraged by railroad surveys into the district, but none of these have ever materialized into a railroad, and cheaper transportation is no nearer than it was 20 years ago.

Several attempts have been made to smelt ore on the ground, but with little success. In 1877, before a wagon road had been built, a small blast-furnace was constructed at Cooke City, and about 60 tons of bullion was smelted, by using charcoal, made nearby, as fuel. The ore was produced at the Republic, Shoo Fly, and Elkhorn mines. The bullion remained in the furnace

THE DISCOVERERS OF THE COOKE MINING DISTRICT, HORN MILLER AND CHARLES CONNON, AT THE GRACE MINE.

until a raiding party of the Nezperce Indians, which was being chased by General Howard during the Nezperce war, carried part of it away to make bullets to use against the soldiers. The Indians were also resourceful enough to cache the remainder for future

use. In addition, they cut up and carried away all leather belting found at the smelter, and took whatever else was detachable. Not much more was done in the way of mining until the district was eliminated from the Indian Reservation and opened for entry in

FALLS ON THE UPPER CLARKSFORK.

1882. The surface, however, had been previously well prospected. At this time there was a rush to the district, and all of the old mineral claims were necessarily re-located, and hundreds of new ones staked out. After the rush to the district considerable work was done, but very little ore was found rich enough to stand the cost of transportation to the railroad. Since then, however, small shipments of high-grade ore have been made from time to time from various mines in the district to outside smelters. A second attempt at smelting was made in 1883, when the Republic company built a small blast-furnace at the mine, which was run at intervals up to 1910. The main production of this Company, however, was before 1886. Previous to that time, 420 tons of bullion had been smelted and hauled by wagon to the railroad station at Cinnabar, which was then the terminus of the Park branch of the Northern Pacific railway. At the smelter coke was used as fuel, and was brought in by wagon.

A copper blast-furnace, which made two short runs, was erected in 1906 by the Cooke City Smelting Co.

One of the runs was made in 1906 and the other in 1910. The operation of the smelter during these periods evidently was not successful. Since there are now about three railroad cars of coke and 100 tons or so of ore in the smelter bins at this time, presumably some cause, in addition to the high cost of transportation, is responsible for the discontinuance of the operations of the plant. Another attempt at smelting on the ground was made in the early eighties, when a Hartfield portable furnace was built on Miller mountain. This furnace, however, did not prove to be a success.

At the end of the first ten years, 450 claims were being actively held out of 1450 which had been previously located. Up to the present time, about 3500 claims have been located; of these about 200 are patented, 200 are still held as locations, and the remainder have been apparently abandoned. Assessment work, however, is not being done each year on every unpatented claim. In order to avoid assessment work, the practice is to locate certain claims from year to year. A large proportion of the locations are being held by old-timers who have more claims than they can properly represent. Most of the best claims have been gathered into groups and patented, and have passed into the hands of mining companies that are controlled by outside capital.

Neither development work, nor production, has progressed steadily at any of the properties. In many instances companies have raised some money, made a spurt with a large force of men, only too often to be as quickly involved in difficulties and forced to shut down. At the present time everything is inactive, awaiting the coming of a railroad, except a few of the smaller properties in the outlying districts which employ a few men occasionally. The population of the district has been fluctuating. It has varied from 1800, as reported one winter when the Republic mine was operating, to 20 or 30 in some of the winters of late years. Ordinarily there are more people at Cooke City in the summer time than in the winter, as many of the regular inhabitants spend the winters elsewhere.

Geology

The geology of the district is interesting, and the good exposures of the formation afford many opportunities to see the geological features. The rocks of the southern part of the district consist of sedimentaries cut by intrusives. In the northern part the country rock is granite. The western portion of the district was covered by the same basic lava flow described by W. H. Weed as covering the greater part of the Yellowstone National Park. The elevation of the mining region existing at the time of the lava flow was higher than the main part of the park, as the streams in this locality have cut through the lava, which is now seen only as cappings on some of the mountains, while in the park the stream beds are in the lava. The whole of the district was covered by the ice field, also described by Mr. Weed as covering the park after the close of the volcanic era. Remnants of this ice field are still

found in the mining district in the shape of small glaciers on some of the higher peaks.

The sedimentary rocks consist mainly of limestone, impure quartzite, and shale, with no individual bed of any great thickness, and generally limited to a few feet. These rocks are metamorphosed at the contact with the larger igneous intrusions. The strata are all quite flat, varying from the horizontal at the northern end of the sedimentaries, to a dip of ten degrees to the southwest at the Republic mountain. The occurrence of the intrusive rocks is quite general, and they are found in various quantities, ranging from dikes 2 ft. in thickness to great masses. Although the formation is cut up by numerous fissures, it is not badly faulted, and the orebodies are generally found in place.

Lead-Silver Ores

The lead-silver ores are found mostly in the limestone, but also occur in the other sedimentary rocks and at the contact of these rocks and porphyry. Copper and gold are found both in granite and porphyry in this locality. The lead ore, at the depths reached in the district, has shown itself to be free from zinc, except in a few instances. Development work is not expensive, as none of the rock is very hard, and all of it stands well without timber, but the workings in the limestone and in some of the porphyry cave after a few years, so as to become inaccessible, if no attention is given them. It is often claimed that the New World mining district has more ore in sight, considering the amount of development work, than any other district in the world. While this is probably an overstatement, the fact remains that there are scores of partly developed low and medium-grade orebodies in the district. Both oxide and sulphide ores outcrop all over the region, and there are few places in the country where there are as many surface showings of mineral. In the greater number of mines no ore is actually blocked out, as one face of the body seems to satisfy the owners as to the permanency of the ore-shoot and the amount of ore available.

The Republic property has been the most important producer in the district up to the present time. The mine was discovered while the country was still in the Indian Reservation, and was re-located when the Reservation was opened to entry. It is owned by the Buffalo-Montana Mining Co., and is under the management of M. J. Tredinnick. The orebodies occur in a bed of limestone about 150 ft. thick, which overlies shale. The main development work consists of two adits, 300 and 500 ft. long respectively, driven on the vein. Several ore-shoots have been developed that assay well in silver and lead, but not high enough to warrant the 65-mile wagon haul. Some high-grade ore has been found, but it is reported that the ore will average about 50 oz. silver and 10 to 15% lead. The ore not being rich enough to ship direct, a smelter was built in the early days to treat the ore on the ground. This smelter has run intermittently up to the last few years, but no great production has been recorded. It is

now, of course, out of date. It costs \$20 per ton to freight the bullion to the railroad, and the same amount to bring the coke and other supplies to the smelter. Evidently, under the existing handicaps, the Company has not been able to operate the works at a profit. The ore is more or less zincy, which would also have an effect on the operations of the furnace.

The Alice E. is a gold mine on the south side of Henderson mountain, and was located in 1884. The orebody is in a porphyry intrusion, and it is reported that an adit 300 ft. long, and a cross-cut 100 ft. long, are all in ore that will average about \$30 per ton in gold. The workings are now caved. A cyanide mill stands on the property, but never ran any length of time, as the ore is base, and a small percentage of copper was soon encountered.

The Daisy is a lead-silver mine at Daisy Pass. The vein is a fissure in the bedded sedimentaries and in porphyry. The ore is mostly of concentrating grade, although there is a small amount of ore of first class. A small shipment of ore, of a gross value of \$85 per ton, was sent to the smelter in 1896. A mill has been constructed on the property, but ran only about two weeks on some rich ore, after which it was permanently shut down. The mine has been quite extensively developed, and has more than 2000 ft. of workings. The main adit, which has a connection through the mountain, cannot be inspected now, as it is completely filled with ice. As a result of the connection, the ventilation through the adit in the winter has frozen the dripping water, which does not thaw during the summer.

The Copper King is a copper mine situated at Goose Lake, and is operated by the Goose Lake Copper Co., under the supervision of John Martin. The ore consists of high-grade sulphides, and occurs in bunches in a strong persistent fissure vein 17 ft. wide in the granite. The vein is developed by an adit about 350 ft. long, and by a shaft about 100 ft. deep. Thirty-seven tons of ore, which ran 16% copper, was smelted at the Cooke City Smelting Co.'s plant in 1910. Some work is being done each year on the property.

The Scotch Bonnet property consists of 14 claims west of Daisy Pass, at the headwaters of the Clark's Fork river. The country rock is a light colored acid porphyry of varying composition. Several large orebodies have been developed on the group—one of which, on the Spaulding claim, is over 35 ft. wide, with its length not yet determined. It consists of solid pyrite carrying over \$20 in copper, gold, and silver.

Another orebody, on the Lizzie claim, is 167 ft. wide, and consists of milling rock carrying about \$7 per ton in copper, gold, and silver. About 1500 ft. of development work has been done on the group. In this age of copper leaching, it may be interesting to note here a case of natural precipitation of copper. At the base of the hill on the Scotch Bonnet property are found several small springs carrying copper in solution. This water runs into a small peat bog, and the copper is deposited in the peat and vegetable muck in the form of small shot-like particles.

Among other properties in the district in various stages of development are the Seward, Young Bonanza, King and Queen, Yellow Jacket, and Homestake.

Mining in the whole district is now practically at a stand-still. Companies owning the best properties, as stated before, have patented their claims and are sitting back to await the coming of the railroad. Many of their adits are caved, and their shafts are either

COPPER KING MINE AT GOOSE LAKE.

caved or full of water, and it is next to impossible to get a good idea of the ore reserves in the district, without expending a large sum of money. Many of the mines do not even employ a watchman. There is, of course, some work going on, but this is almost entirely in the nature of assessment work on unpatented ground, and done by men who do not have the money to get their claims patented. The assessment work on the whole is done in a very perfunctory manner, and in such a way that a little work goes a long way in representing a claim; but even, at that, more work is done for a hundred dollar assessment here than in most camps in the West. About 30 claims are represented each year by the local residents for outside people. For the last few years the money paid for this work is all that has been put into circulation, and has kept the spark of life in the district. Prospects of a railroad keep interest alive in the district, and many expect ultimately to realize large returns on their investments.

The operators say that enough work has been done to demonstrate that a profit cannot be made without transportation, and there is no need to mine ore and pile it on the dump and wait indefinitely for the road. On the other hand, no doubt a line would have been built into the district long since, if there was enough ore in sight to justify so doing.

The latest railroad project is that of the Eastern Montana Electric Railroad Co., which, within the last year or so, has made a survey for an electric line from Billings, up the Clark's Fork of the Yellowstone river, to Cooke City. Negotiations are now under way with the Department of Agriculture for a right of way across the National Forest, and for permits to construct power plants to furnish electricity to run their trains. A steam railroad is already in operation to Belfry, which is about 55 miles from Cooke City, and on the line of the projected road. The people resident in the mining district have great hopes that this road will be built, and point out that, beside the ore that would be hauled from Cooke City, there is a forest of merchantable timber along the Clark's Fork, a sulphur deposit at Crandall creek, and the Pat O'Hara irrigation project on the creek of that name, which would all be tapped by this line. Another reason for building this road probably as strong as any, is that it will furnish an entrance to the Yellowstone National Park, which, in the hands of a transeontinental road, would be a valuable asset. The real mountain scenery about Cooke City is far superior to any found in the Park, and has the added attraction of the glaciers. The scenery up the Clark's Fork is also better than along any of the branch railroads reaching the Park. All this could be featured, and no doubt if the road is built this entrance would be extensively used. With the advent of automobiles in the Park, the disadvantage of the forty-mile ride to the main tourist route would be materially lessened.

The camp has been comparatively free from litigation, and has been the scene of only a few of the ever-to-be-expected squabbles of stockholders among themselves. It is reported, however, that some of the properties in this district were shut down and never started again for this reason. It may be well to add that there is hardly a mine in Montana that is closed down, but that the inhabitants of the district claim that it is a case of 'big fish eating the little fish,' and that the mine will start up again as soon as the small stockholders have been frozen out. It is seldom admitted that the mine is not operating because it is out of ore, or because it does not pay to work it.

The fact that the owners of the 200 patented claims have elected to patent their ground and then let it lie idle has been the main drawback of late years in securing the much needed railroad. If by some law, work, only enough in amount to keep the workings open, had been required of the mine owners, it would materially help the railroad situation, inasmuch as it would enable examining engineers to see all of the ore that has been opened up in the district instead of that in only a few cases. A law similar to the Australian form, which

calls for a specified amount of labor being performed each year on all claims under penalty of forfeiture, may not be practical in the country as a whole, but it would certainly be a great benefit to this district. The showings are so good in the district that very few claims would have reverted to the Government, had such a law been in force. If one hundred dollars worth of work, the amount required on unpatented claims each year, had been done on each of the 200 patented claims for the last 20 years, the total amount expended would have gone a long way toward proving the size and permanency of the orebodies.

There has been very little wild-catting in this district, but one company has been active during the last few years along this line. In this case, a man secured the assets of a mining company at a sheriff's sale for \$1700, under an attachment for his salary as president of the Company. He then proceeded to organize a new company, and sold stock on a \$3,000,000 basis. He has reorganized his company several times since, under a more rosy prospectus each time, but it seems that no great amount of stock has been disposed of. What money has been raised has gone to pay his salary and office expenses, and no actual mining work has been done.

Costs at the Nipissing Company

Costs at mines and mills are generally calculated on a per ton basis, but at Cobalt, Ontario, the silver mining companies publish them on this and also on a per ounce basis. The last report of the Nipissing Mines Co. shows the following costs, based on a production of 77,240 tons milled and 4,552,172.59 ounces:

| | Per ton ore. | Per oz. silver. |
|---|-----------------|--------------------|
| Hydrauliciking and clearing land | \$ 0.554 | \$0.0094 |
| Diamond-drilling | 0.093 | 0.0016 |
| Development and exploration | 3.685 | 0.0625 |
| Stoping | 2.191 | 0.0372 |
| Loading and sampling | 0.064 | 0.0011 |
| Assaying, engineering, and research..... | 0.151 | 0.0025 |
| Administration and office | 0.381 | 0.0065 |
| Boarding house and camp maintenance | 0.278 | 0.0047 |
| Insurance and taxes | 1.013 | 0.0172 |
| General and legal expense | 0.366 | 0.0062 |
| High-grade mill | 0.618 | 0.0105 |
| Low-grade mill | 4.144 | 0.0703 |
| Custom milling by Nova Scotia Co. | 0.017 | 0.0003 |
| Depreciation | 0.793 | 0.0135 |
| Marketing product | 0.305 | 0.0052 |
| Corporation, New York office, and traveling.. | 0.155 | 0.0026 |
| | <hr/> | <hr/> |
| | \$14.808 | \$0.2513 |
| Less rents and interest | 0.615 | 0.0104 |
| | <hr/> | <hr/> |
| Total operating cost | \$14.193 | \$0.2409 |

Sand-lime brick manufactured in the United States in 1913 was valued at \$1,238,325. Michigan was the leading producer. Prices range from \$6.27 to \$10.61 per 1000 bricks. The industry has been the victim of 'boomers'.

Radium and Its Sources

By CHARLES T. KENNAN

A great deal of interest is now being taken by the public in the sources and physical properties of radium, and general lack of information seems to prevail regarding the fundamentals involved. Therefore the following brief statement of source of the more salient facts may be of interest.

Radium is a chemical element.

Uranium is a chemical element.

Radium is a transformation product from uranium.

Radium is not found 'free' in nature, but is obtained only as a transformation product from uranium. Radio-activity is the property a substance has of emitting a certain kind of invisible ray. The radio-active elements are radium, uranium, thorium, polonium, and actinium. Radium was discovered, not by direct observation, but through its effects.

Rays of Radium

The rays of radium are divided into three classes, according to the physical properties exhibited by each, and are designated by three Greek letters, alpha, beta, and gamma.

The alpha rays have little penetration, and are stopped, or absorbed, by an ordinary thick sheet of paper. They have very little photographic effect. They are electrically positively charged particles. These are the strongest ionizers, that is, when allowed to pass through a non-conducting gas they make it a conductor of electricity—this effect is called ionization. Ninety per cent of all the rays are alpha rays.

The beta rays have more penetration than alpha rays, but are absorbed by a thick sheet of copper or tinfoil, or five millimetres thickness of aluminum. They have the greatest photographic effect, but less power of ionization than alpha rays. Nine per cent of the rays are beta rays. They are negatively charged particles. These rays are found to stimulate the growth of cancer.

The gamma rays have the greatest power of penetration, and will pass through thirty centimetres of iron, or a half-inch steel bar, without apparent diminution in intensity. These rays travel through space at the rate of about 185,000 miles per second. They have little photographic action, and little power of ionization. They do not appear to be charged with electricity. These are the rays used in the cure of cancer. By wrapping metal foil around the tube of radium salts, the alpha and beta rays are excluded from passage, while it is no obstruction to the gamma rays. Only one per cent of the rays are gamma rays, but these are the most wonderful of all. Of all the radio-active elements, radium has the strongest rays, and the element is about 1,000,000 times more active than uranium.

Radium exhibits the wonderful power of continuous emission of energy in the form of heat without any diminution of its substance, and from no source except itself. It is found that one-half grain of radium bromide gives out heat at the rate of two calories per hour. Radium is usually placed upon the market in the form of radium bromide, or radium chloride—the latter containing 76% radium, and the former less than 59 per cent.

The ratio of radium to uranium present in any unaltered mineral, as pitchblende, is constant, and stated by Rutherford and Boltwood to be 0.0000038 gm. of radium to 1 gm. of uranium; or, in other words, one ton of 60% uranium ore will contain two-tenths of a gram of radium. An exception to this rule has very recently been noted in favor of certain carnotite ores. It takes about 215 tons of 2% uranium ore to produce 1 gm. of radium, if 100% is saved.

More than 40 different uranium minerals have been discovered, of which pitchblende, carnotite, alunite, and torbernite have been of commercial importance—pitchblende and carnotite having thus far produced practically all of the radium supply. Pitchblende is the richest ore of uranium, frequently carrying between 50 and 80% uranium. Uraninite is a crystalline variety of pitchblende.

Pitchblende in commercial quantities has quite invariably been found in fissure veins in the old igneous rocks such as granite, gneiss, schists, etc., and always associated with gold, silver, copper, lead, zinc, or tin ores. It is considered essentially the black oxide of uranium, but always contains many impurities, usually massive and amorphous. The color of pitchblende is pitch black to brownish, sometimes with grayish or greenish cast. The ore is brittle with a dull, metallic, and pitch-like lustre. The fracture is conchoidal, and hardness from 5 to 6. Its specific gravity is 9 to 9.7 in crystals and 6.4 and higher in massive form.

Carnotite

Carnotite, named after Adolphe Carnot, a noted French chemist, is considered to be a hydrous vanadate of uranium and potassium, but is probably a mixture of minerals, the exact nature of which analysis fails to reveal, though to a considerable extent made up of calcium and barium compounds. It is usually found in sandstone and sometimes in other sedimentary rocks. It practically always occurs in 'pockets' or 'chimneys,' and isolated discontinuous deposits of comparatively small size; a 'pocket' producing 50 tons of shipping ore is considered a good deposit. The color is a bright canary yellow. Carnotite is found in powdery form, or in slightly cohering masses, and as yellow stain in rock crevices, or in a calcareous sandstone. Hereto-

fore buyers have refused to handle ores containing less than 2 per cent U_3O_8 . The carnotite ores, as shipped from Paradox valley, Colorado, have averaged about 2.5 per cent U_3O_8 and 3.5 per cent V_2O_5 .

While prices have been variable, yet as based upon the uranium and vanadium content, perhaps the following scale would be an average:

| | Per pound. |
|---------------------|----------------|
| 2% U_3O_8 | \$1.30 |
| 2.5% U_3O_8 | 1.40 |
| 3% U_3O_8 | 1.50 |
| V_2O_5 | \$0.30 to 0.50 |

If the scale of prices is based upon U_3O_8 alone, it is then worth \$2 to \$2.50 per pound; but on 5 to 10 per cent U_3O_8 , \$2.75 per pound, and for 10 to 20%, and higher U_3O_8 , \$3 per pound. The probable maximum cost in Europe of extracting radium from carnotite is \$20 per milligram, corresponding to \$20,000 per gram. The average price of radium bromide is \$70 per milligram, corresponding to \$70,000 per gram, or \$2,000,000 per ounce; and for radium chloride, \$90,000 per gram. During the year 1912, for which approximate statistics are available, it is certain that American ores produced more than twice as much radium as all other sources combined and practically all of this ore was mined in Colorado. It is reliably estimated that during the year 1913 American ores contributed 60% of the world's production of radium for that year. Two large plants for the extraction of radium are now in operation in Pennsylvania, each said to be of larger capacity than any similar works in Europe.

That the United States has produced such a large proportion of the radium ores does not necessarily imply a paucity of such ores elsewhere, but is rather in the nature of a handsome compliment to the superior energy and enterprise of the American prospectors and miners, as, even at this early stage of the industry, it has become quite apparent that such ores are widespread and abundant, having already been found in many states of the Union, including Montana, Washington, Idaho, Wyoming, South Dakota, Utah, Colorado, Arizona, and New Mexico, also in Germany, Bohemia, Austria, Sweden, Russian Turkestan, Portugal, Peru, England, and Australia.

The value of the secondary metals, exclusive of gold, silver, platinum, and iron, recovered in the United States in 1913 was \$72,845,000, according to J. P. Dunlop, of the U. S. Geological Survey. Even this large figure is a decrease compared with 1912, when the value was \$77,396,000. The term secondary is applied to metals recovered from scrap metal, sweepings, skimmings, drosses, etc., as distinguished from primary metals, which are derived from ore, but without implication that the secondary metals are of inferior quality.

Mineral paint output of the United States in 1913 amounted to 392,812 tons worth \$34,666,473. This includes natural mineral pigments, pigments made directly from ores, and chemically manufactured pigments.

Fellowships in Metallurgy

By an act of the legislature of the state of Utah, which became effective July 1, 1913, there was established in connection with the State School of Mines, a department of the University of Utah, a metallurgical research department. The particular purposes for which this department was established are the "finding of ways and methods of profitably treating low-grade ores, of securing a higher percentage of extraction of metals from their ores, of obtaining other information that shall have for its object the benefit of the mining industry."

By an agreement with the United States Bureau of Mines, the work of this department is to be under the direction of metallurgists of the Bureau, assigned to duty at the University and Salt Lake City. Since January of this year the metallurgist of the Bureau, D. A. Lyon, has been in charge of the work, assisted by other members of the metallurgical staff of the Bureau.

In connection with this new department there have been established five research fellowships in metallurgy, each having an annual value of \$720. These fellowships are open to college graduates who have had a good training in chemistry and metallurgy, and applications for them will be received up to June 15, 1914. Applicants should send a copy of their records from the registrar's office of the college where they have, or will be, graduated, and the names and addresses of at least three references who know their character, ability, and attainments.

Due to the fact that Salt Lake City and vicinity is one of the chief non-ferrous metallurgical centres of the United States, and that the work which is taken up is of a practical nature, that is, has to do with the solution of definite problems, the University believes that these fellowships offer a splendid opportunity to young men intending to enter the metallurgical profession, to thoroughly familiarize themselves with up-to-date metallurgical practice, especially in the treatment of non-ferrous ores, and to become proficient in the adaptation of those processes which may be in line with the investigation carried on by them in connection with their work.

Holders of these fellowships will be subject to the rules governing employees of the U. S. Bureau of Mines, and will report for duty about September 15, 1914. They must also register as students in the University of Utah and become candidates for the degree of Master of Science in Metallurgy (unless this or an equivalent degree has been previously received). Their class work will be directed by the heads of the departments of instruction, and their laboratory work, as previously stated, by metallurgists of the Bureau of Mines. Fellows are appointed for one year, but the appointment may be renewed. Address applications to Jos. F. Merrill, Director of the Utah State School of Mines, Salt Lake City.

The Engineer's Office

By CARL A. ALLEN

Probably of all the engineering professors he who follows mining has the greatest variety of problems to solve and in his office are to be found books, periodicals, maps, and specifications covering nearly the whole field of engineering, as well as chemistry and geology.

In an endeavor to economize space and make available the material in a general engineering office, I have evolved a few very simple methods that may be of benefit to others. Large engineering corporations and large mine offices have elaborate and efficient methods and sufficient clerical and engineering help to carry them out, but there are many small engineering and mine offices where the engineer, the superintendent, and a draftsman or book-keeper, is about all the clerical force available, and the methods used must be simple or they will not be successful. The Dewey system of classification, as explained later in this article, is not simple to learn and may require considerable application, but after once thoroughly understood it is simple, and the only method that has stood the severe tests of the public libraries.

Methods of Filing Maps

There are many ways of filing maps, the principal of which are: (a) filing flat in drawers, (b) rolling and placing in drawers or deep pigeon holes, (c) placing on rollers attached to wall or ceiling, making it possible to roll the map up like an ordinary window curtain, and (d) filing in books. Of these, filing in drawers is one of the most common and one of the most unhandy where a large number must be handled. The drawers take up much space, it is difficult to remove a map without disarranging all the others, the corners of disarranged maps are apt to be torn when the drawer is pushed in, and it is difficult to get a map back in its proper place among the other maps after it has been taken out for reference. It has the advantage of keeping the map flat and a map can be quickly found. The rolling of maps requires more space for filing, unless they are rolled together, and then it is difficult to get at those on the inside of the roll. Rolled maps will persist in rolling up and will not lie flat. Large maps must necessarily be rolled, however, and only one map should be placed in a roll. This one should be carefully marked on the outside. Nothing is better for large maps to which constant reference is being made than the curtain roller, but the space required, and also the expense, forbids the consideration of this method for small maps. The fourth method, of filing maps in books, obviates practically all the disadvantages of the others and has proved to be a very simple and convenient method. The illustration shows two different ways of making the books. The book shown on the left of Fig. 1 has two covers, and this is probably the best form, where the maps will seldom have to be removed,

but the books are expensive. The back cover only is used on the book on the right of the illustration and the maps are filed on arches, as is often done with invoices or duplicate bills. The back is made of what is known as panel or drawer bottom material, which costs about 10c. per square foot. For small maps cheaper material may be used, such as compo-board; and for large maps a special panel may be made, built up like a door, which prevents any chance of warping. The posts or arches cost 25c. each, making the cost of a book in which to file 24 by 36-in. maps a little over a dollar, if ordinary panel material is used. I am using four different sizes as follows: Size D, 12 by 18 in.; size C,

FIG. 1. METHOD OF FILING CLIPPINGS.

18 by 24 in.; size B, 24 by 36 in.; and size A, 36 by 48 in. Any map larger than 36 by 48 in. is rolled. A border is left on the left hand edge of the map for filing and the edge should be doubled over or an extra piece glued on where the holes are punched, as this prevents the holes from tearing out. Fifty to 100 maps, 24 by 36 in., may be filed in one book without having too much weight, and the books can be placed in drawers or, if space is an item, can be hung up by hooks on the wall.

One mistake that is often made in making maps is not to have standard sizes. If standard sizes are not adopted, a bunch of maps of all possible dimensions will soon be accumulated. The dimensions above noted are all even feet or half feet, mostly multiples of 24 by 36 in. Maps 12 by 12 in. (or 8½ by 11 in., sometimes necessary to use in letter size reports) can be filed in a 12 by 18-in. book; 24 by 12-in. maps may be filed in a 24 by 36-in. book, and so on, making possible a map

or 'Useful Arts,' which general division may be subdivided in the following manner:

- 610. Medicine.
- 620. Engineering.
- 630. Agriculture.
- 640. Domestic Economy.
- 650. Communication and Commerce.
- 660. Chemical Technology.
- 670. Manufactures.
- 680. Mechanic Trades.
- 690. Building.

These divisions are again subdivided into parts. Number 620, or 'Engineering', is divided as follows:

- 621. Mechanical Engineering.
- 622. Mining Engineering.
- 623. Military.
- 624. Bridge and Roof.
- 625. Road and Railroad.
- 626. Canal.
- 627. River and Harbor.
- 628. Sanitary. Water Works.
- 629. Other Branches.

Mining Index

Mining Engineering has the number 622, and books or articles numbered 622 would be placed on the shelf between those numbered 621 and those numbered 623. As the classes are divided into ten divisions and the divisions are each divided into ten parts, so the parts are subdivided and this subdivision can be carried as far as desired. In the original classification it was carried to five figures and for a general library this is sufficient. For the library of a mining man, however, it is not enough. For example, 622.69 is Surface Transportation. The average mining engineer will accumulate too many articles that would be classed under Surface Transportation, but which would be different; as, for instance, Aerial Tramways and Wagon Roads. Hence, a further extension or subdivision is necessary, and such an extension was prepared by me and published by the Colorado School of Mines as Volume Seven, Number Three of the *Quarterly*.

The Dewey system has stood the test of libraries, but it has been but very little adopted by engineers, because many engineers will not take the trouble to become familiar with the system and also because libraries have large numbers of books, while engineers have relatively few books on one distinct subject but a vast number of articles that occur in the technical press. The technical magazines may be bound in book form, but their contents form a heterogeneous mass of information and it is this material that must be made available to the engineer.

Many engineers keep a card index of these articles. Each card describes and tells where a certain article can be found, and these cards are arranged in the file in alphabetical order according to the subject; **timbering** would come under T, etc. Here the Dewey system can be applied by numbering the cards and placing the

cards in the file in numerical order. An article on **timbering** would be given the number 622.28 and placed in the drawer between cards numbered 622.27 and 622.29. This obviates the disadvantages of an alphabetical index as already noted and where the engineer does not keep in his office the articles to which the cards refer, the card index arranged numerically is probably the best method of keeping track of articles in the technical press.

There are two very serious disadvantages to the card index. First, the time required to keep it up to date. An engineer must probably make out three or four cards for each magazine received; often the magazines accumulate and are misplaced before the cards are made out. Second, it is difficult and requires time to put on a card sufficient data to tell just what the article contains. This means that when any information is wanted the cards must be gone over to find what articles are available, then the articles hunted up, with the chance that some may not contain just the information wanted and that others may be hard to find.

Magazine Index

These serious disadvantages have led me to adopt the following method. When a magazine arrives and is read the binding clips are removed as shown in Fig. 1, each article is taken out and numbered according to the Dewey system; if the article covers two sheets, they are bound together; then they are filed away just as a letter would be filed, except that they are arranged according to number. The filing can be done in pigeon holes or in any of the books or drawers used for filing letters. There is one disadvantage to the scheme which can best be illustrated by an actual example. In the *Mining and Scientific Press* for August 16, 1913, on page 268, there is an article on 'Transportation in the Orient.' This article, if cut out and filed, would have the number 622.69, but the other side of the sheet contains the last part of an article on 'Under-Estimating the Cost of Milling Plants,' which would have the number 622.79, and, of course, the two articles could not be filed in the same place. What can be done in this case is to put pages 267 and 268 in the article on 'Transportation in the Orient' together and file under 622.69 and the first four pages of the articles on milling plants together and file under 622.79 with a note written at the bottom of the last page that the remainder of the article will be found with 622.69, 'Transportation in the Orient.' This is the method that must be used when two articles valuable for reference conflict, unless another copy of the paper can be secured. Unless both articles are very valuable, however, I usually discard the one less likely to be needed for reference, because after all it is quality and not quantity that counts. It is better to have a small amount of material immediately available, under a simple system which will be kept up to date, than it is to have a large mass of material not quickly available and which, for indexing, requires an amount of work that will not be done by the average busy engineer.

Gold Placers on the Kuskokwim River, Alaska

By H. W. REETH

A number of new discoveries have been made within the past few years on the lower Kuskokwim. While no bonanzas have been found, pans of sand assay from 1 to 25c. on different rivers in the district. The field, as far as prospected, promises to be an extensive one, both for hydraulicking and dredging. A number of claims were recently purchased in the Eel River district, and the first payment has been made. Work will commence in the spring. On two of these claims 25c. per pan is frequently found, and 5 and 10c. per pan is a common yield. At present there is a mystery in Bethel about a discovery which is said to be rich.

REINDEER-SLEIGH IN ALASKA.

and pans often yield several dollars. The gold is found as nuggets and coarse shot above the bedrock, which has not been reached. On the Kwisluk river there were some claims sold last summer, and there is a large vein of arsenic-bearing ore carrying gold and silver. The coal seam is in sandstone formation and is reported to be four feet thick. Riglugalie, Tuluksak, and Anyagak rivers promise to become producers in the near future. The last two have produced considerable gold in past years by working on a small scale.

The greatest drawback in developing this country is the lack of transport facilities, as there is no regular steamer service between Seattle and Bethel. Prospecting is expensive, and there are no large mines working at the present time. Men were paid \$1.25 per hour last summer, and were hard to get at that wage. The living and transportation costs are quite high. So it may be said that it is a country for capital and not for a poor man.

The reindeer is a useful animal for the mining industry in this district, being good for both food and freighting purposes. Their meat sells at 20c. per lb. in Bethel, and freight is 5c. per lb. to Tuluksak and 2½c. per lb. to Riglugalie river. One reindeer can haul 200 lb. with ease and make 30 miles

per day, and with good roads 50 miles and over. The annual reindeer convention was held at the village of Akiak, and J. H. Kilbuck reported that 7000 reindeer are in this district, a territory 100 miles long and about 25 miles wide. There was present at the convention the Rev. Adolf Stocker from Kwinhagak, Rev. S. H. Rock, F. Drebert, and Mrs. Boyd, the government school-teacher, from Bethel, together with 25 reindeer herders. Arrangement was made to subdivide the herd and place them on tracts with certain boundary lines between each herd. Interesting races have been run with reindeer. The first one took place in 1912 and was won by the same Indian that won the blue ribbon this year. This was the government chief herder, Karl Kavalag, from Kwinhagak. The distance was five miles, which was covered in 16 minutes, there being no track. Here is a good opportunity for quick and good mail service during the winter season. The Government has a large herd of reindeer in this country, and by building stations, say 50 miles apart, along the survey of the Alaska Short-line railway, which is surveyed from the Iliamna bay to Anvik on the Yukon, a distance of about 469 miles, such a service could be established. This would make nine stations in all, and the mail could be delivered on the Yukon in nine days, and on Kuskokwim in about seven days. During the short days in December it would take a little longer, perhaps. There is good feeding ground for the deer all along the route, so they could be stationed there the year round, and move the mail from station to station in the winter without any hardships to the men or deer.

Phosphate rock was produced and sold in the United States in 1913 to the amount of 3,097,021 long tons, valued at \$11,767,092, according to W. C. Phalen, of the U. S. Geological Survey. This was an increase over 1912 of 123,689 long tons in quantity and \$91,318 in value. The main output of phosphate rock came, as usual, from Florida, Tennessee, and South Carolina. Florida continued to be the leading state in the industry. The production of Idaho and Wyoming amounted to only one-fifth of 1% of the whole. The quantity of phosphate marketed in Florida in 1913 was 2,531,076 long tons, valued at \$9,533,945. Compared with 1912, this was an increase of 124,177 tons in quantity and \$72,648 in value. The amount of phosphate rock marketed in Tennessee in 1913 was 451,559 long tons, valued at \$1,774,392.

With 32 Nissen stamps, 5 tube-mills, and a cyanide plant, the new Shamva plant in Rhodesia crushed 18,078 tons of ore and treated 6713 tons yielding gold worth \$26,000. Absorption during this first run was 58 per cent.

There are 333,000,000 acres of public lands in continental United States, and approximately 370,000,000 acres in Alaska, or a grand total of 700,000,000 acres in all.

Soluble Losses

By HARAI R. LAYNG

The subject of soluble losses occurring in cyanide plants has received only a small proportion of the study and attention to which it is entitled from those persons who are in charge of the operations of cyanide plants. Visits to some of the larger of those plants of Central America, Mexico, and the United States have caused the truth of the previous statement to be forcibly impressed upon me.

Discrepancies Due to Losses

Soluble losses are in some cases the cause of serious discrepancies occurring between the actual and theoretical recoveries, when the theoretical recovery is based upon the difference between head assays and tail assays. An example of such a case is taken from a well known mill in Honduras some few years ago. At this place a usual difference varying from 3 to 5% occurred monthly between the actual and theoretical recovery. The theoretical recovery was based upon the difference between the head and tail assays, and it was usually the 3 to 5% greater than the actual recovery, mostly due to the unestimated soluble loss. The tail sample was taken from the Butters filter-leaf holding the washed cake, by means of a scoop attached to the end of a stick, the sample being scraped from one or two leaves of each charge by means of the scoop. The sample from each charge was dumped into a pan which held all of the charge samples for 24 hours. When the pan would be nearly full the sampler would pour off any solution from which the pulp had settled, in order, I presume, to make room for more of the charge samples. The worthlessness of such sampling is obvious, especially in a mill where the solution entering the zinc-boxes would assay over 20 oz. silver per ton, yet nevertheless I have seen the same or nearly the same method practised in more recent times in other well known mills. One can well imagine the extent of the undetermined soluble loss which occurred at the mill in Honduras upon considering the losses as shown in the examples which follow hereinafter.

Tailing Sample

A somewhat common method of sampling filter tailing is to take a cut or so from the washed cake before it is discharged from the filter-leaf. I have always found this method to be incorrect, more especially so with the Butters or Moore type of filter. Some reasons for its unreliability are that in taking the sample the sampler usually selects a cake which is not frozen, that is, one which does not adhere to the opposite cake contained on another leaf; coarse particles or heavy particles of ore, such as concentrates, which have a tendency to concentrate close to the filter medium during cake making, are not caught in the sam-

ple owing to the unevenness of the filter surface caused by slats or cocoa matting; and the failure to obtain solution in the sample which was discharged with the cake and which remained in the pipe connections and spaces of the filter-leaf at the end of the wash before discharging.

A number of carefully conducted comparative tests which I have made have proved in each and every case that the leaf sample was lower than a properly taken flume sample.

The following tests were made at a mill treating about 1000 tons of ore per day using a Butters filter which made a 60-minute cake with a 60-minute wash, and are examples of the foregoing statement. The unwashed pulp entering the agitators rarely assayed over \$4.

| Charge. | Sample. | Tail assay washed. | Au. oz. unwashed. | Soluble loss by difference | Solution: | | Soluble by solution assay |
|---------|---------|--------------------|-------------------|----------------------------|-----------|---------------|---------------------------|
| | | | | | Assay | Ratio ore = 1 | |
| A | leaf | 0.035 | 0.035 | none | 0.003 | 1.04 | 0.0031 |
| A | flume | 0.035 | 0.05 | 0.015 | 0.027 | 0.91 | 0.0245 |
| B | leaf | 0.027 | 0.03 | 0.0033 | 0.0045 | 1.08 | 0.0049 |
| B | flume | 0.035 | 0.045 | 0.01 | 0.013 | 1.0 | 0.013 |

The method used in sampling at this mill prior to the operators learning of the unreliability of the leaf sampling, some few months ago, was very similar to the method described in the fore part of this article. According to the difference between the solution solubles of the leaf samples and the flume samples as shown by charge B, the company operating the mill was losing over \$61,000 per year more than it was aware of. The loss was mostly due to frozen cakes, and a few simple changes in the filter and filtering overcame most of the loss which had theretofore been unrecognized. The following figures show the smallest difference found between the soluble of the frozen and non-frozen cakes:

| Charge. | Sample. | Tail assay washed. | Au. oz. unwashed. | Soluble by difference | Solution: | | Soluble by solution assay |
|---------|-------------|--------------------|-------------------|-----------------------|-----------|---------------|---------------------------|
| | | | | | Assay | Ratio ore = 1 | |
| C | leaf | 0.027 | 0.03 | 0.003 | 0.0045 | 1.08 | 0.0049 |
| C | frozen leaf | 0.027 | 0.05 | 0.023 | 0.036 | 0.92 | 0.033 |
| C | flume | 0.035 | 0.045 | 0.01 | 0.013 | 1.0 | 0.013 |

A considerable difference is shown in the foregoing

figures between the soluble loss as shown by solution assay and that as shown by the difference between washed and unwashed sample assays. This difference is partly due to the difficulty of obtaining close assays when charges of only one assay-ton size are taken for assay. The main reason for the difference is probably due to the method used in drying the unwashed sample. The possibility of error in soluble determination by the differential method arising from the method followed in drying samples containing soluble metal is shown by the following:

Flume sample C was thoroughly mixed and divided into four portions. Portion 1 was dried in a clean tin pan in the customary manner of ordinary practice. Portion 2 was enclosed in oiled paper and dried, the paper was reduced, and its gold content found and calculated. Portion 3 was treated with acid copper sulphate followed by sodium sulphite and a little sodium sulphide to precipitate the metals, then it was dried and assayed. Portion 4 was mixed with water, filtered, and washed in a filter-press, the filtrate measured and assayed, and the residue dried and assayed. The following results were obtained:

Soluble by difference between washed and No. 1=10.00c. per ton
 Soluble by difference between washed and No. 2=19.63c. per ton
 Soluble by difference between washed and No. 3=27.69c. per ton
 Soluble by solution assay (No. 4) =26.87c. per ton

Another example is shown by the following:

Sample dried as ordinarily=10.33c. per ton soluble
 Sample dried in oil paper=20.95c. per ton soluble
 Soluble by solution assay=24.80c. per ton
 Washed sample =28.68c. per ton

The above figures clearly show in the case of the particular ore that drying samples in clean tin pans does not give correct results. This is probably due to the concentration or precipitation of the soluble metal on the pan. In these cases an electric stove was the heat medium for drying.

I have noticed the same effect in drying silver ores in Honduras, but as I cannot find record in my notebooks I am unable to give the figures.

The subject of drying samples containing dissolved metal is quite interesting from the evidence shown by the foregoing examples, and it should be investigated more thoroughly than I have investigated.

The soluble loss of cyanide varies considerably, and the rate does not follow any fixed rule. In a mill where water is none too plentiful and where solutions are not wilfully discarded, the soluble loss of cyanide through a Butters type of filter averages about 0.6 lb. KCN per ton when the circulating solution averages about 1.2 lb. KCN. The soluble loss in cyanide is quite an item, and I believe that it will be overcome to a great extent within the near future.

An Underground Timber Truck

By P. B. McDONALD

An underground timber truck is used for transporting timber, dynamite, rock-drills, drill steel, heavy machine parts, etc. They are very convenient in a

large mine. A timber truck should be low, light, and strong, with wheels near together for easy pushing, as one man usually trams it.

As is evident from the sketches, the truck here shown has four holes for 1-in. round iron stakes at each end.

for holding on round mining timber. The gage of track is 2 ft., the frame is of 4 by 8-in. oak, the axles are immovable and of 2-in. square mild steel. The wheels are substantial and of manganese steel, and the truck is well bolted together.

Talc and soapstone production of the United States in 1913 was 149,271 and 26,562 tons, worth \$1,280,020 and \$628,077 respectively. This country is the greatest producer in the world of these minerals. Most of the output comes from the Eastern states.

Bauxite production of the United States in 1913 amounted to 210,241 tons valued at \$997,698.

MACHINERY HALL AND EASTERN FACADE OF THE PALACE OF MINES AND METALLURGY.

The Model Mine—Panama-Pacific Exposition

Beneath the floor of the Palace of Mines and Metallurgy, there will be constructed a model mine. From either side of two main parallel drifts there will be, on one side, model coal-mining rooms, and on the other side, model metal mining stopes, each of such dimensions as may be appropriate to the mine represented. The mine drifts and working places will be outlined in metal lath, plastered with cement plaster, and in this will be embedded the appropriate ore and wall-rock, or coal, or slate, as it occurs in the several mines represented. The mine is to be truly coöperative, each exhibitor bearing his portion of the expenses.

There will be reproduced metal mine stopes illustrating mines in such characteristic districts as the Mother Lode, California; Comstock or Goldfield, Nevada; Coeur d'Alene, Idaho; Anaconda, Montana; Mesabi, Minnesota; Gogebie, Michigan; Joplin, Missouri; Bisbee, Arizona; and Franklin, New Jersey; and typical coal mines from various parts of the country.

These will be provided by the mine owner or groups of owners concerned in such a manner as to reproduce as accurately as possible the interior appearance of such working places as they occur in their mine. The makers of mining machinery or appliances in use in each particular mine are to place in the model mine such machinery as they sell to the mining company concerned. The cost to each party involved will be inconsiderable. It is estimated at a minimum of about \$300. The manufacturers will place in the various mine stopes or rooms the mining machines or appliances which they sell.

The Bureau of Mines will, through its engineers and other permanent employees, transact the business connected with constructing and operating the coöperative mine, furnish the necessary engineering superintendence during construction and operation, and will, if desired, supervise the placing of the materials and timbering, or the mining machinery, in the several mining rooms or stopes.

The entrance to the mine will be through the Bureau of Mines space in the Mines and Metallurgy Building. Visitors will be given portable mine lamps, and will be lowered in a mine cage which will move very slowly to the level of the mine floor beneath the building floor. A panoramic effect of the strata and lining of a mine shaft will move by them rapidly so as to produce the illusion of descending a considerable depth. Passing into the main drift they will come to the various mines, the names and locations of which will be displayed, and they will see the mining machinery and appliances in place as shown or demonstrated by the makers.

The only concern the Bureau of Mines has in this, and the chief concern which mine owners or machinery makers can have in it, is a public-spirited and coöperative interest in the welfare of the mining industry as a whole, and an unusual opportunity to illustrate to a vast audience the extent, diversity, complexity and expense of conducting mining operations throughout the United States.

Approval of the project and recommendation to their principals for coöperation has been had from the following, and there is every reason to expect favorable action in the immediate future:

An Anaconda Copper Mining Company, stope; a Minnesota Iron stope; a Mother Lode, California, stope; a Comstock, Nevada, stope.

Coal mines will be illustrated by an Oklahoma coal mine; a Pittsburgh, Pennsylvania, mine; an Illinois mine.

Electric locomotives have been promised by the Westinghouse company of San Francisco; mine pumps by Byron-Jackson, San Francisco; air-compressor, drill sharpeners, etc., by the Compressed Air Machinery company, San Francisco; mine cage, track, and cars by the Joshua Hendy company, San Francisco; 'Justrite' carbide lamps by the Justrite company, Chicago; and tunnel signs will be furnished by J. W. Stonehouse, of Denver.

Dredging in Russia in 1912

Translated by WILLIAM H. SHOCKLEY

In *Zoloto i Platina* for January 14, 1914, is a condensed table of the results of dredging in Russia for 1912. These figures give the result of the yearly investigation that is undertaken by the 'Permanent Consulting Board of Gold and Platinum Producers' and show that answers were received from 18 companies operating 52 dredges (one more than in 1911). Full details, on which the averages in the following tables were based, were received from only 42 dredges (six less than in 1911).

The following operators did not send information: Yenesei Gold Mining Co.; Novo Udilsk G. M. Co.; Orsk G. M. Co.; Tantyarska G. M. Co.; 'Central Siberia'; Uskova; and Oleminsk G. M. Co. The following did not work during the year: Bogoslovsk G. M. Co.; Verk-Isetsk Works; and Putiloff Works, and therefore no statistics are available.

In the following it is seen that the number of hours worked per dredge increased from 3026.67, in 1911, to 3137.53, in 1912, that is, about 3.7%. The ground worked increased 0.6% and the output of precious metals 3.7%. The total production of gold and plat-

inum in 1912 was 654 oz. greater than in 1911, or about 0.6 per cent.

These figures show that there has hardly been any increase of production in 1912. Therefore, unless poorer ground, accidentally worked, be taken into account, the conclusion is forced that there has been little technical improvement during the year 1912.

(Classified production by dredges:

| Ounces. | Number of dredges |
|-----------------|-------------------|
| Less than 527 | 3 |
| From 527 to 790 | 1 |
| " 790 " 1053 | 7 |
| " 1053 " 1317 | 7 |
| " 1317 " 1580 | 7 |
| " 1580 " 1843 | 3 |
| " 1843 " 2107 | 5 |
| " 2107 " 2370 | 6 |
| " 2370 " 2633 | 1 |
| " 2633 " 2897 | 6 |
| " 2897 " 3160 | 1 |
| " 3160 " 3423 | 1 |
| 4402 | 1 |
| 5011 | 1 |
| 7094 | 1 |
| 7879 | 1 |
| Total | 52 |

Comparison of the results of the past five years:

| | 1908. | 1909. | 1910 | 1911. | 1912. |
|---|----------|----------|----------|----------|----------|
| Number of hours worked per dredge | 2,502.24 | 2,771.57 | 2,914.93 | 3,026.67 | 3,137.53 |
| Number of cubic yards worked per dredge | 166,363 | 186,892 | 182,488 | 212,268 | 213,438 |
| Amount of metal produced per dredge, oz. (Troy) | 1,434 | 1,811 | 1,792 | 2,021 | 2,096 |

The following footnotes present details regarding the production statistics presented in the table on the opposite page.

¹Dredge made at Werf Conrad works, Haarlem, Holland 1906.

²The volume of the ground excavated by the dredge is frequently checked by comparing the volume obtained by counting the number of buckets, with the actual volume excavated as determined by measuring the ground; from this measurement is deduced a coefficient by which the volume estimated by counting the buckets can be corrected.

The machinery made in England by Arthur Brown. The dredge was built locally. The dredges began working: No. 1, early in August 1908; No. 2, middle of April 1908; No. 3, June 26, 1910; No. 4, June 27, 1911; No. 5, June 24, 1911; and No. 6, May 20, 1912. None of these dredges carry the name of the maker. The cost of the dredges was as below:

| No. | F.o.b. Tagil, without cus- tom duties. | Custom duties. | Construction pontoon and transportation. | Total. |
|--|---|-------------------|--|----------|
| 2 | \$38,248 | \$15,993 | \$34,600 | \$88,841 |
| 4 | 37,744 | 19,008 | 32,628 | 89,380 |
| 5 | 37,744 | 19,008 | 33,941 | 90,693 |
| 6 | 38,835 | 16,118 | 37,620 | 92,573 |
| No. 1 and No. 2 paid no custom duties. | | | | 142,266 |

Putiloff Works dredge.

³Dredge built by the Neviansk Works, 1903.

⁴Dredge built by the Neviansk Works, 1907.

⁵Dredge built by the Neviansk Works, 1911.

⁶Dredge built by the Neviansk Works, 1905.

⁷Dredge built by the Neviansk Works, 1907.

⁸Dredge built at the Neviansk Works, 1907.

⁹These dredges (26 and 26a) work jointly, one removes the top dirt to one side; the other follows and excavates and washes the exposed gravel. Made by Werf Conrad in 1900.

¹⁰Small dredge, not over 30 or 35 hp. Upper portion of soil and stumps removed by hand. Made by Tatz, 1905.

¹¹Close-connected buckets. Putiloff Works, 1911.

¹²Own dredge, made in 1907.

¹³Own dredge, made in 1908.

¹⁴Own dredge, made in 1909.

The following factors may be found useful in converting Russian statistics into English standards.

| | |
|---|--|
| One pood | 36.113 pounds. |
| One pood pure gold | 21.157 rubles = \$10,886.72. |
| One zolotnik = 0.137 Troy ounces = 2.835 of pure gold | 5.5964 rubles. |
| One dolya | 0.0014286 Troy ounces = \$0.029532 of pure gold. |
| One 2000-lb. ton | = 55.382 poods. |
| One pood | 0.0180561 tons. |
| One ruble | \$0.541567 = 25.375 pence. |
| One ruble per cubic sagene | \$0.04053 per cubic yard. |
| One ruble per pood | \$28.50 per ton, \$0.01425 per pound |
| \$0.009977 per Troy ounce | |
| One zolotnik per cubic sagene pure gold | = \$0.223 per cubic yard. |
| One zolotnik per cubic sagene | approximately for placer gold \$0.20 per cubic yard. |
| One dolya per cubic sagene pure gold | \$0.0023245 per cubic yard. |
| One dolya per cubic sagene of placer gold | approximately \$0.002 per cubic yard. |
| One zolotnik per 100 poods pure gold | = \$1.57 per ton, 2000 pounds |
| One dolya per 100 poods | = \$0.0164 per 2000-lb. ton. |
| One zolotnik per 100 poods of placer gold | = approximately \$2 per cubic yard. |
| One dolya per 100 poods of placer gold | = approximately \$0.02 per cubic yard. |
| One cubic yard of gravel | is reckoned as 3000 pounds |

¹⁵Own dredge, made in 1910.

¹⁶Own dredge, made in 1912.

¹⁷Close-connected buckets. Putiloff Works, 1904.

¹⁸Besides the washed sand, 13,929 cu. ft. of surface soil was removed.

¹⁹Shaft work.

²⁰Dredge of New Zealand type, made at own works in 1909; cost \$31,000.

²¹The measurement of the worked ground is given by the advance of the dredge along the fixed head-line by the direct measurement of the depth (by sounding rod), and of the width of the excavation. Werf Conrad dredge, 1900.

²²In this total the 230,759 cu. yd. of top dirt excavated by dredge 26a of the Platina company is not included.

PRODUCTION OF URAL AND SIBERIAN DREDGES FOR 1912

The Pyritic Ore Deposits of Kyshtim, Russia

By A. W. STICKNEY

*This deposit is a compact, dense, massive aggregate of granular pyrite, barite, and quartz, carrying irregular blotches, streaks, and minute grains of chalcopyrite, sphalerite, and tennantite. The evidence indicates that the ore is the result of the metasomatic replacement of alternating bands of a sheared and broken schist by a rather fine grained, cracked, and broken pyrite, anhedral barite, and quartz. This granular aggregate contained considerable open interstitial space, which was later filled by contemporaneous chalcopyrite, sphalerite, and tennantite. Tennantite probably also marks a slightly later stage in the primary mineralization, and with it are contemporaneously associated chalcopyrite and quartz of a second generation. The paragenesis of the sulphide minerals is one of decreasing iron and increasing copper content.

The orebodies, as viewed in a vertical section, normally show four distinct, roughly horizontal and parallel zones. From the outcrop downward they may be designated as: (1) the gossan zone, which extends from the surface to a maximum depth of 60 ft.; (2) the zone of loose baritic sand, extending from the bottom of the gossan to a maximum depth of 150 ft., the greater portion of which lies beneath the level of the ground-water; (3) the loose, leached sulphides, which reach from the bottom of the baritic sand to a maximum depth of 180 ft., where they gradually pass into (4) the underlying, firm, massive, mainly unaltered sulphide ore.

The evidence indicates that the gossan is the result of normal processes of oxidation acting upon the massive sulphide ore, since the gossan (a) displays the honeycomb skeleton form of the primary ore with the metallic sulphides removed; (b) overlies a much narrower zone of loose baritic sand, which carries only about one-fourth as much iron as the gossan, and is strikingly distinguished from the gossan zone by a broken and caved hanging wall; and (c) this broken hanging wall reaches the surface in the case of the one lode of which the outcrop is predominantly baritic sand. It is believed that during a period in the remote past the rate of denudation has been much faster, as the result of a steeper gradient or of glaciation, whence the massive pyritic ore was kept so near to the surface that an excess of oxygen was always immediately available to convert into limonite the iron of any ferrous sulphate formed. Since that time these conditions have ceased to exist, owing to long continued erosion or to climatic changes. The baritic sand is regarded as the result of leaching by surface waters, which probably contains sulphuric acid, but were deficient in oxygen: the iron sulphate and much of the copper sulphate

thereby generated were lost by diffusion into the relatively more permeable wall-rock.

As this leaching has occurred to as great a depth as 110 ft. below the ground-water level, which apparently has been stationary for a long period, it is inferred that the upper portion, at least, of the ground-water is not so stagnant as some have supposed. A distinct circulation of this water, both vertically and horizontally, is suggested. There is no evidence to support the hypothesis that the gossan was formed by iron sulphate solutions, ascending through the underlying extensive zone of baritic sand, the iron being fixed as limonite in the gossan by descending surface waters heavily charged with oxygen. There is nothing to suggest that gossan is being formed at the present time; on the contrary, it is inferred that all the present gossan is a remnant of that formed in a previous period, which has not as yet been removed by erosion except in the case of one lode, where topographic conditions appear to have been and are still favorable to rapid denudation. Here the underlying zone of baritic sand outcrops.

Downward enrichment of secondary sulphide does not occur in the form of a shallow, well developed, commercially important, horizontal zone, typical of many other localities, but has taken place to a relatively slight degree along the immediate walls, especially the hanging wall, to the greatest depth yet attained in exploration, which is 600 ft. below the ground-water level.

The massive pyritic ore of a given lode shows a progressive longitudinal variation in relative mineralogical character, from a condition of maximum intensity of mineralization near the longitudinal centre of the lode, which continues downward to the greatest depth yet reached.

The character and composition of the ore, and the nature of the hydrothermal alteration of the wall-rock indicate that the deposits have been formed through metasomatic replacement, along a sheared zone of the schist, by pyrite and barite, molecule by molecule, band by band, thus preserving the original banding of the schist; also, that the deposition took place during a distinct mineralizing epoch, marked by solutions progressively changing in composition and depositing a series of sulphide minerals in transitional order. From the absence of characteristic ore minerals in the adjacent altered country rock, and the presence of sericite, barite, and quartz, it is concluded that the mineralization was effected by hot alkaline solutions at a temperature and pressure corresponding to what Lindgren in his 'Mineral Deposits' calls the zone of intermediate depth.

Diamonds exported from Antwerp to the United States in 1913 were worth \$13,374,474, against \$10,903,894 in 1912. Antwerp is now the centre of the diamond industry of Europe. Exports from Amsterdam were \$11,070,862. The new international carat weight for diamonds is 200 milligrams.

The Boston & Montana Plant

By C. W. GOODALE

*At a meeting of the Society in New York on March 19, 1914, Mr. Goodale gave the following information about the work being done at this plant:

It was some time ago decided by the Anaconda Copper Mining Co., the operating Company, that concentrating should no longer be done at Great Falls. Up to the present time there has been treated about 3000 tons per day, and soon the Anaconda concentrator will

BASIC CONVERTER AT BOSTON & MONTANA PLANT.

be so increased in capacity that it can treat a larger tonnage and then ship concentrate, about 1000 tons per day, to Great Falls. It is easy to see where that is the logical thing to do, as the concentrator at Great Falls is old, some of the plant dating back 23 years, and the cost of building a concentrator on modern lines would mean a large expenditure. Furthermore, the cost of hauling ore from Butte to Great Falls is about 75c. per ton, against 14c. from Butte to Anaconda, 25 miles. The management at Great Falls will be sorry to see an important department of its operations taken away, but that is the logical outcome of conditions.

An expenditure of more than \$2,000,000 was authorized in 1912 for replacing the main smelter building at Great Falls with a higher and stronger structure, and for new and modern furnaces and converters. Last year the old main smelter building, 51 by 704 ft., with a height of 23 ft. 7 in. to the crane rails, was removed, and the new building occupying the same site was completed. It is 824 ft. long, with a width of 56 ft. and a height of 42 ft. to the crane rails. Three old cranes of 40-ton capacity were replaced by three new ones of the same capacity, but with modern improvements. The walls of the building are of brick.

The three new basic-lined converters, 20 ft. diameter, are in place, and the old one, 12 ft. diameter, are set aside. One of these bowls had a record of 20,000 tons of copper blown without relining, and when discarded it was in condition for indefinite further use. The converters which were originally installed

in 1891 were 7 ft. diameter; then came the 12-ft. and finally the 20-ft. converters.

The new reverberatory furnace has been built, and results show such an improvement over the work done by the old gas-fired furnaces that another one is now being built. The hearth is 102 ft. long and 22 ft. wide, and the firebox is really a large gas-producer, in which can be gasified more than 100 tons of coal per day, while the old producers could only handle 10 or 12 tons per day. No provision has yet been made for pre-heating the air used in combustion, but hot-blast stoves will soon be built for the purpose, and it is expected that the present capacity of 250 tons of charge per furnace-day will be increased to more than 300 when these stoves, which will use the waste-heat of the furnace, are in action. The present ratio of coal to charge is about 1 to 2½, the fuel being of rather inferior quality (22% ash). There are some new features in the construction of the furnace, particularly in the binding, the usual buckstays and the rods across the top of the furnace being avoided by the use of a heavy steel-plate shell with a number of angle-braces on the sides, provision being made for expansion and contraction.

The old McDougall roasters, 16 ft. diameter, will be discarded as soon as the 24-ft. furnaces are built. The present blast-furnaces are 15 ft. long, but in the new plant E. P. Mathewson's lead will be followed and they will be built longer. At Anaconda, preparations are being made to use pulverized coal in the reverberatories, and, judging by results obtained in other places where coal-dust firing is in use, a considerable saving will be effected in costs of smelting.

India possesses large water-power resources, which are gradually being utilized. The Cauvery Falls scheme, in Mysore, is being enlarged from 10,000 to 17,000 hp. This supplies the Kolar group of gold mines at \$48 per horse-power year. By far the most important hydro-electric undertaking that has ever been projected in India is being carried out at an estimated cost of \$8,000,000 in the Bombay Presidency by the Tata Hydro-electric Power Supply Co., Ltd. It will provide about 60,000 hp. and will be supplying energy by February 1914. Contracts have already been signed for supplying power to 31 cotton mills and 3 flour mills in Bombay. The financing of this enterprise, to which nearly \$1,000,000 was contributed by the royal families at Hyderabad, Mysore, and Boroda, was largely assisted by the wealthy Parsee community in Bombay. Two reservoirs will have capacities of 380,000,000 and 2,800,000,000 cu. ft. respectively. Later on a third reservoir with a capacity of 7,000,000,000 cu. ft. will be constructed. The transformers for this plant are being supplied from Schenectady, New York; the insulators, transmission lines, underground cables, etc., from both England and Germany; the pipe lines from Switzerland, and the Pelton type wheels from California.

*Abstract from Bull. 71, Min. and Met. Soc. of America.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Relative Efficiency of Sodium and Potassium Cyanide

The Editor:

Sir—I read in your issue of April 18 C. M. Eye's criticism of Mr. Butters' article on the above title in which are incorporated detailed figures by Mr. Hamilton. At this writing Mr. Hamilton is in Salvador, Central America, and it will be some little time before the matter can be called to his attention for his comment on it. Mr. Butters is in the hospital in this city. Therefore, I take the liberty of stating that I have checked over the figures in question and, assuming that the prices of 17c. and 22c., for potassium and sodium cyanide respectively, as given in Mr. Hamilton's table, are correct, I quite agree with Mr. Eye that the loss per ton of ore due to using sodium cyanide is between 21 and 22c., instead of 16c. per ton.

G. W. SHEPHERD.

New York, April 28.

The Simplification of Gold Ore Treatment

The Editor:

Sir—I am indebted to John B. Stewart for a criticism¹ of my article² on the simplification of gold ore treatment, which dealt with the suggested abolition of amalgamation in favor of complete cyanidation.

Mr. Stewart draws attention to an alleged avoidance, in my article, of essential simplifications which may result from such a change of policy; and, referring to the question of the statement of costs, he says: "The advantages of detailed cost data are now too generally recognized, and applied, by competent metallurgists, to warrant the assumption that the practice of cyaniding without amalgamation is only fashionable." I cannot see that this sentence has any significance whatever in connection with the matter under review. The advantages of detailed cost data are just as obvious where amalgamation is practised; and, under such circumstances, they may be recognized and applied by competent metallurgists with equal facility as in the instance where amalgamation has been abolished.

Mr. Stewart continues: "It should scarcely be necessary, at this date, to reiterate the various arguments regarding the evils attending all attempts to cyanide after previously crushing in water * * *." A reply to such a sweeping generalization is not an easy matter. The practice of 20 years' standing can hardly

be termed an attempt; and as regards the alleged evils of milling in water, my experience has been that they are not noticeable when compared with the complications liable to arise and the economic disadvantages which invariably result from the practice of milling in cyanide.

While on this subject, I would draw attention to an interesting comparison which may be made between two plants, in the same district, in one of which milling in cyanide has been adopted and in the other milling in water. The figures are taken from H. A. McGraw's articles which appeared in *The Engineering and Mining Journal* of November 23 and December 21, 1912, and from the same authority I learn that the ores are identical in character:

| Treatment. | Hollinger Mill. | Dome Mill. |
|--|-----------------------------|---|
| Solution precipitated per ton of ore.... | (Milling in cyanide) 4 tons | (Milling in water) 2 tons |
| Zinc consumption per ton crushed | 0.80 lb. | 0.25 lb. |
| Cyanide consumption per ton crushed... | not stated | 0.80 lb. |
| Cyanide added | before precipitat'n | before agitation |
| Total recovery | 93% | 95% with "no difficulty in recovering 98 or 99% if desired to do so." |

The question of the milling in cyanide of an amalgamable gold ore is a side issue in the present discussion, but since Mr. Stewart has whetted our interest by a reference to the arguments which might be brought forward in support of the method, I have prepared some notes on the subject for a future issue of the *Press*, and I look forward to comments and criticisms with expectant interest.

Reverting to the question of the abolition of amalgamation, the letter continues: "All schemes have had satisfactory trials, and the present custom of dispensing with amalgamation has been established through good results." Here again Mr. Stewart indulges in an avoidance of actual fact. Amalgamation is not as dead as he would have us believe; neither is it the custom to dispense with its obvious advantages. It is, as a process, still responsible for about half the world's output of gold; and my article on the subject was an effort to counteract the effect of statements which are periodically made by extremists, and whose recommendations have an influence both on the younger members of the profession and on those whose lack of technical training and experience prevents them from estimating the true value of advice on metallurgical matters.

As regards what Mr. Stewart terms the general abandonment of amalgamation in conjunction with the cyanide process, I would draw attention to the fact that the principal mines in the world are still using amalgamation, in conjunction with cyanidation, as the chief method of gold recovery. On the Rand over 60% of an immense annual output is due to amalgamation. At the Homestake the monthly yield

¹*Mining and Scientific Press*, September 20, 1913.

²*Mining and Scientific Press*, August 16, 1913.

is in the neighborhood of \$500,000, and three-fourths of this is the result of amalgamation treatment. Further figures showing the importance of amalgamation can be found in connection with the statement of output of the principal mines in Australia and New Zealand, as well as America.

With regard to the good results which Mr. Stewart assures us have been instrumental in the general abandonment of amalgamation, I append a few figures adapted from *The Mining Magazine*, dealing with the work of amalgamation-cyanidation plants on a group of properties known as the Rand Mines, Ltd., during 1912:

| | Reduction cost per ton. | Av. val. ore. | Extraction, %. |
|---------------------------|----------------------------|------------------|----------------|
| Modderfontein B... | \$0.87 | \$9.05 | 96.20 |
| New Modderfontein | 0.87 | 9.27 | 97.59 |
| Rose Deep | 0.94 | 7.14 | 93.98 |
| Geldenhuis Deep | 1.09 | 7.45 | 95.68 |
| Nourse Mines | 0.90 | 7.38 | 95.89 |
| City Deep | 0.89 | 8.75 | 96.73 |
| Village Main Reef | 1.10 | 9.71 | 95.09 |
| Village Deep | 0.83 | 7.20 | 96.17 |
| Ferreira Deep | 1.07 | 9.99 | 95.97 |
| Robinson | 0.96 | 10.48 | 96.38 |
| Crown Mines | 0.86 | 7.94 | 95.32 |
| Bantjes | 0.98 | 7.27 | 96.40 |
| Durban Roodepoort Deep... | 0.97 | 7.50 | 95.04 |

At the Homestake the average value of the ore is about \$4. The extraction amounts to about 94%, and the cost per ton for reduction treatment amounts to about 20 cents.

For the purpose of comparison, the figures upon which Mr. Stewart bases his remarks on the subject would be of interest.

Mr. Stewart next deals with what he terms " * * * mechanical considerations, based on the relative efficiency, indicated by comparing the cost of operations with recovery. " * * * " He also says that my article seems confined to the question of recovery. As a matter of fact, I made the direct statement that amalgamation was the most economical method of gold recovery. It was for Mr. Stewart to directly controvert this statement with argument or figures. In the absence of either, I retain my position.

The abolition of amalgamation often necessitates an expensive fine-grinding equipment. An increase in the grade of ore cyanided involves an increase in capital expenditure on other parts of the plant which is far in excess of the cost of copper plates. At the Homestake, as at the Great Fingall, the amalgamation treatment is so successful that the cost of slime agitation, both as regards cost of plant and cost of operation, is entirely obviated, and the fine material is treated direct in the presses. Depreciation on copper plates, when milling in water is practised, is the lowest charge of this kind as compared with the other parts of the plant; and a large proportion of the original sum expended is realizable at the conclusion of operations. This is far from being the case with regard to cyanide plant equipment.

Mr. Stewart next deals with the question of theft, and his contentions cannot be disregarded. On the other hand, and if there is an open possibility for loss from such a source, then direct smelting of the ore with litharge and the production of a base bullion would ultimately displace cyanidation as a process.

The criticism then returns to the question of milling in cyanide, and we read: "The one objection which appears to have outlived all others is that it has deprived its operators of their justly prized screen sample, upon which the original value of the ore, and all subsequent calculations, are based. Indeed, for this reason alone, it has frequently been debated in South Africa whether it might not be wise to resume crushing in water once more for the sake of the accuracy of the head sample obtained from the battery screens." Mr. Stewart's ideas as to South African practice form a fitting sequel to his remarkable pronouncements about amalgamation. I have only recently returned from the Rand, and I saw no indication that milling in cyanide would ever be seriously considered, much less generally adopted, as an alternative to present practice.

Mr. Stewart then says: "But I doubt whether the exasperating details attending the need of eliminating the water, to preserve the economical bulk of stock solution, etc., will ever be compensated for by this [a reliable head sample] and the slightly improved extraction to which our attention has just been called." The spectacle of the metallurgist tearing his hair at the idea of having to dewater his mill pulp is of too Gilbertian a conception to justify serious argument. Dewatering must precede filtration in any case, and it is a far more practicable operation before cyaniding is commenced. It is, of course, imperative that the equipment for the purpose should be designed to dewater to within a few percentages of moisture contained in the discharged residue. If this is impossible, then milling in water is either impracticable or inadvisable.

'Float values' are next discussed, and we read: " * * * the millman is far more often financially embarrassed by the 'float values' than is the cyanide man by coarse gold." Financial embarrassment is a universal complaint, but why any millman should be so encumbered on account of 'float values' passes my comprehension. There is certainly no need for him to worry because float gold is undoubtedly the easiest gold to dissolve in the cyanide plant. Mr. Stewart continues: "In fact, I think that the ultimate gain in recovery due to the 'float values' recovered only by crushing in cyanide, has of itself often decided the question in favor of abandoning amalgamation." I should be interested to learn how Mr. Stewart proposes to induce his 'float values' to get any benefit from the crushing machinery; or to point out how the solution of the gold could be more effectively insured in the mortar box than in a properly designed agitation vat. 'Float gold' is likely to escape from the battery at the earli-

est opportunity to find its way, together with classifier overflow, direct to the cyanide plant. The fact that 'float gold' is not easily amalgamable is no argument against the practice of amalgamating coarse gold.

The next paragraph contains an inquiry dealing with the question of additional cyanide strength and also cyanide loss as a result of increased metal content. It is, I think, common knowledge that necessary cyanide strength bears a definite ratio to the amount of metal to be dissolved and precipitated. This is an experience which covers gold ores and concentrates from 1 dwt. to 10 oz. per ton, and silver ores and concentrates from 3 oz. to 250 oz. per ton. With every increase in cyanide strength there is an increase in cyanide loss due to (1) the solution of the metal and lack of regeneration, (2) from the formation of hydrocyanic acid, and (3) from the solution of excess zinc during precipitation. When milling in cyanide is practised, the custom of precipitating a part of the mill solution is general and obligatory; but whether or not a large proportion is precipitated, depends on a number of circumstances, chief of which arises from the fact that an increase in the amount precipitated generally means an increase in the zinc content in the solution and an increase in cyanide loss. When operations are being conducted at an economic disadvantage from either cause, then the amount of mill solution to be precipitated must be reduced, and this has often to be done in order to obtain good precipitation, and prevent undue fouling. In the cyanidation of silver ores a much larger bulk of the mill solution may be precipitated daily without interference with the efficiency of a process which leaves an appreciable amount of dissolved metal in the 'barren' solution. The low value of silver, as compared with gold, makes the operation an economic success. On the other hand, the percentage of precipitation in silver cyanidation is exceptionally good even with a high zinc content. This may be due to the increased bulk of metal or possibly to improved electrolytic action; in any case it is helped by a high cyanide strength and a high zinc and cyanide consumption which would be economically impossible to justify in the treatment of a low-grade gold ore. One method of avoiding this excess consumption is indicated in a description of the Mexican Esperanza mill.³ In this plant the sodium cyanide consumption is given as 0.5 kg. and the zinc consumption as 0.195 kg. per wet ton. What a wet ton is, I do not know, but I take it that the actual consumption expressed in a rational manner would not be materially different from these figures. The obvious economy which ultimately affects a number of items beyond those mentioned is in a great measure due to the fact that the Merrill process limits the amount of excess zinc which is exposed to the solvent action of the cyanide. A second point to be noticed is that one of the chief disadvantages of milling in cyanide is overcome in this installation. The

milling dilution, with Huntington mills, is only 4 to 1, as against 10 to 1 in most other mills; and the amount of solution precipitated amounts to only 3 tons per ton of ore, as against twice or three times that amount in cases where ordinary stamp-milling is practised. The degree of dilution when milling in cyanide is practised, largely affects the ultimate economy of operations. In the great majority of cases a high dilution is necessary to maintain tonnage and prevent a low mechanical efficiency. On the other hand, the cyanider's paradise is indicated in some ingenuous charts in recent circulation, with involved mathematical calculations, showing the ease and simplicity with which a recovery of dissolved gold and silver may be made by the aid of a special method dependent for its success on a total milling and sliming dilution of from 1.8 to 1!

Reverting again to the comparison made earlier in this letter to the schemes of treatment at the Dome and Hollinger mills at Porcupine, it is interesting to note that, in the case where milling in water is practised the cyanide make-up is added before agitation, the total cyanide consumption is, if anything, below the average, and the zinc consumption is exceptionally small. On the other hand, and in the case where milling in cyanide is practised, the cyanide for make-up is added before precipitation, the zinc consumption is high, and the cyanide consumption is not stated. My own opinion is that the necessity for the addition of fresh cyanide to the solution to be precipitated is, almost invariably, one of the first indications of fouling; and this is generally due to the fact that a large tonnage of solution is being precipitated, coupled with a too complete retention of undesirable by-products in the circuit. The former is the result and the latter is the concomitant of the practice of milling in cyanide.

I regret that Mr. Stewart should have considered that a definite statement to the effect that zinc precipitation was never complete could be interpreted as a hasty implication that the gold in the so-called barren solution was irrecoverably lost. The fact that the solution after precipitation does carry gold, and that the amount is generally in direct proportion to the original value of the solution, was purposely mentioned because such gold content is an important factor in the ultimate dissolved gold loss in the residue.

Mr. Stewart continues: "The cumulative effect [of part precipitation] tends to approach perfection rather than any such loss as has been too hastily implied." The incompleteness of zinc precipitation is an imperfection, however trifling and unimportant, and how the cumulative effects of an imperfection can approach perfection is beyond my powers of reasoning, and outside the scope of logical criticism.

Mr. Stewart has, during his criticism, referred to what he considers the best practice for medium-sized plants. I cannot see what the size of the plant has to do with the main outline of treatment decided upon for a given class of ore, and based upon metal-

³McCann, Ferdinand, 'Cyanide Practice in Mexico,' p. 49.

lurgical results and economic considerations. If the scheme of treatment bore any relation whatever to the size of the plant, then the erection and operation in units would be unproductive of good results unless the scheme of treatment were altered to suit the gradual increase in tonnage. The contention is obviously untenable.

In reviewing the situation, it is interesting to note that the larger gold mines of the world retain a conservatism in method which is the subject of much adverse comment; and at the same time results are produced which are the envy of those who profess no sympathy with any method not of recent innovation. Improvements are being constantly made with regard to the mechanical handling and crushing of the ore, the mechanical displacement of solution from residue, and in other details of operation. I do not refer to such innovations of obvious merit, but rather to fundamental principles affecting the broad outline of treatment.

To quote the editor of *The Mining Magazine*: "In the sphere of mining and metallurgy, as in other branches of science and industry, a feverish desire to be considered up to date is prevalent." In cyanidation the desire has reached the proportions of a mania.

In considering the excellent results obtained by the Homestake plant and also on the mines of the Rand, it is difficult to overestimate the importance of amalgamation. The exceptionally low cyanide residue is in some measure at least due to the low grade of material which is left after amalgamation has removed by far the greater proportion of the gold. The low consumption of chemicals is due to a similar cause coupled with the advantages arising from a restricted limit to cyanide operations, involving a minimum of solution in circuit. And the low cost of treatment is largely due to the fact that there is no necessity to grind the whole of the ore to a slime in order that a minute percentage of gold may be ground and re-ground and so made amenable to cyanidation. The main lines of treatment in the most successful gold-reduction plants in the world are the result of skilled metallurgical control, in design as well as operation, coupled with a disregard of 'up to date' practice when the latter fails to result in either an increase in recovery or a decrease in the cost of treatment.

Since replying to John B. Stewart's criticism of my article on the above subject, I have, thanks to the courtesy of the secretary of the Chemical, Metallurgical, and Mining Society of South Africa, obtained actual figures relating to matters dealt with. One of the points mentioned by Mr. Stewart was to the effect that the advisability of abandoning milling in cyanide in South Africa has been the subject of frequent discussion. Such a remark is obviously misleading, and I am glad to be able to publish the actual figures for 1912 dealing with the Witwatersrand:

| | |
|--|------------|
| Tonnage milled in water | 25,317,711 |
| Tonnage milled in cyanide solution | 168,650 |

Milling in cyanide was adopted at two large plants several years ago. At one of these a change was made to milling in water soon afterward, and for sound economic reasons. At the present time there is only one plant running on the Rand where the ore is milled in cyanide solution, and even in this instance a change would be made to rational and proved practice were it not for the fact that limitations of space in the mill preclude the possibility of alteration. In no instance has the question of the reliability of the head sample been the paramount cause for the adoption of milling in water, although the question when raised can be used as one of the many arguments in favor of the practice.

A second point raised by Mr. Stewart was to the effect that amalgamation in conjunction with cyanidation had been generally abandoned. As South Africa produces such a large proportion of the world's output of gold, the following figures, which are approximately correct and refer to 1912, are of more than local interest:

| | |
|--------------------------------------|---------------|
| Value of yield by amalgamation | \$117,110,000 |
| Value of yield by cyanidation | 67,011,000 |

A. W. ALLEN.

Lonely Mine, Rhodesia, December 13, 1913.

[It is entirely too common to take things for granted, and the rapid increase in the use of cyanide has, possibly, made metallurgists too ready to give up the older process of amalgamation. Mr. Allen's further contribution to the discussion of the relative advantages of the process is, therefore, worth while. We regret that circumstances have prevented its earlier publication, but technical information does not rest alone on timeliness for its value. EDITOR.]

Leaching of Copper Tailing

The Editor:

Sir—I noticed in your issue of May 9 an abstract of a paper presented by me at the last meeting of the American Electrochemical Society. In figure 3 of the advance copies, some of the arrow-heads point in the wrong direction, which is the case with the corresponding figure of your abstract. As this error may easily cause a misunderstanding, I take the liberty of bringing it to your attention.

RUDOLF GAILL.

Miami, Arizona, May 15.

The figure referred to corresponds to Fig. 2 of the abstract, and the flow between S_1 , S_2 , S_3 , S_4 , and S_5 , as represented by the dotted line, should be the reverse of that indicated by the arrows. —EDITOR

A directory, Bulletin 585, of the useful minerals of the United States, totaling 400, has just been published by the U. S. Geological Survey. It was compiled by Samuel Sanford and Ralph W. Stone, and may be obtained free on application to the director of the Survey, at Washington, D. C.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

The personnel of the U. S. Bureau of Mines at June 30, 1913, numbered 391 people.

Carbon used in 20,000 ft. of diamond-drill work at the Dome mine in Ontario, cost 52c. per foot.

Slime-settling capacity of the Belmont 60-stamp mill, Tonopah, designed for treating clean quartzose ore, is 5.65 sq. ft. of settling area per ton milled per day. This is low for talcose material.

Stamp-mills in Queensland, Australia, total 156, with 2040 head, for gold ores; and 30 with 355 head for tin ores. In 1913, 1140 and 115 head, respectively, were idle, 672 and 158 worked part of the time, and 219 and 45 worked continuously.

Stamps, their weights, efficiencies, and costs, are being investigated by a leading metallurgist on the Rand, according to *The South African Mining Journal*. There are 1380 stamps weighing over 1750 lb. each, of which between 1100 and 1200 are at work.

By a strange freak of nature the lowest point of dry land in the United States is less than 80 miles from the highest. The lowest point is in Death Valley and is 276 ft. below sea-level. It is said that from this point Mount Whitney, 14,501 ft. above sea-level, can be easily seen on a clear day.

Silver ores of Ontario contain cobalt, and research work has been done at the Queen's University, Kingston, by H. T. Kalmus and others for its economic recovery. The aluminum reduction method is the most satisfactory; 1 lb. of aluminum will reduce a little over 2 lb. of metallic cobalt.

The value of mineral products exported from the Argentine Republic amounts to about \$500,000 per year. The geological survey of the country is still incomplete and nothing has yet been published. Tin mining is likely to become an important industry, but the condition of mining generally in the republic is stationary.

The construction cost of water-power plants in Norway varies from 100 to 200 crowns (\$26.80 to \$53.60) per horse-power for large plants, and from 100 to 500 crowns (\$26.80 to \$134) per horse-power for small plants. The rate at which the power is sold to consumers varies from 30 crowns (\$8.04) for large enterprises up to 50 crowns (\$13.40) for small ones, per horse-power per year, 24 hours per day service.

Gibs used in stamp tappets should be turned to a diameter slightly smaller than that of the stem which

they are meant to grip. In addition to this, the tappet on the opposite side to the gib should be counter-bored or channeled so as to give two further points of contact between tappet and stem.

Hydraulic mine filling is useful for sealing-off mine fires, putting out fires, arresting squeezes, and supporting the surface, and incidentally improves ventilation by filling old workings where gases are formed from many different causes. In Pennsylvania and Europe, culm, ash, crushed slate, and bone from breakers, sand, gravel, clay, loam, crushed rock, and granulated slag are used.

'Gopher' blasting of overburden at the Chino Copper Co.'s mine, New Mexico, according to R. I. Kirchman, resulted as follows: In six holes were placed 7725 lb. of black powder, 38,500 lb. of Judson powder, and 4100 lb. of 40% gelatin; a total of 50,325 lb. This was tamped, and exploded by electric current. A total of 118,660 cu. yd. of ground was broken, so the powder used was 0.425 lb. per cubic yard, and each cubic yard broken required 2.36 lb. of powder.

Cost of treatment at the Nipissing low-grade mill in 1913, when the 40-stamp mill and cyanide plant handled 77,240 tons of 27.18-oz. silver ore, was as follows:

| | Per ton. | | Per ton. |
|---------------------------|----------|-------------------------|----------|
| Crushing at mine..... | \$0.163 | Treatment | \$1.021 |
| Aerial tram | 0.100 | Filter and discharge... | 0.186 |
| Surface tram | 0.117 | Precipitation | 0.301 |
| Picking plant | 0.217 | Refining | 0.127 |
| Crushing | 0.081 | Heating | 0.113 |
| Battery | 0.267 | Water supply | 0.031 |
| Tube-mills, classifiers.. | 0.547 | Construction | 0.286 |
| Slime collecting | 0.448 | | |
| Intermediate filter | 0.127 | Total | \$4.132 |

In handling gold precipitate after acid treatment, it has been shown that roasting is only necessary in the case where a material amount of metallic zinc is left in the precipitate. Roasting should be avoided wherever possible, and no improvement in the fineness of bullion produced follows its adoption. When zinc shaving is used as the precipitant there are few difficulties in the way of an almost complete removal of the zinc by acid, followed by filtration and washing with hot water. On the other hand, and where zinc dust is used, there is sometimes a considerable percentage of metallic zinc left after acid treatment, and an alternative method of removal of this base metal, such as smelting with litharge, is indicated as advisable. When the ore being treated is high grade, a simple method of clean-up is practicable. This consists of screening the precipitate from the boxes through 40 or 60 mesh, filter-pressing the fine product, and smelting direct. The latter method is often employed after the cyanidation of silver ores, and was also in use for some time at the Oroyo-Brownhill mill, at Kalgoorlie.

LONDON

PROGRESS AND PROSPECTS OF THE PLYMOUTH MINE, CALIFORNIA.

—A NIGERIAN TIN FIASCO: FAULTY ENGINEERING AND THE RESULT.—CRITICISM OF THE NATOMAS CONSOLIDATED CONSULTING ENGINEER'S REPORT FOR 1913.

Progress of development of the Plymouth mine in Amador county, California, is being followed with unusual interest in London. It will be known to many readers of the *Mining and Scientific Press* that at the end of 1911 the California Exploration Co. was formed to acquire and reopen the mine, on the report of Albert Burch, a report that was backed by W. J. Loring, of Bewick, Moreing & Co. The unwatering of the mine was completed in October 1912. The exploration work has proved the nature of the mine on the 950, 1140, 1500, 1600, 1850, and 2000-ft. levels. At the 1600-ft. level an important piece of work was done in sinking a winze to the 1850 and 2000-ft. levels. Both the last levels have been extended in highly profitable ore. Mr. Loring has stated that many of the mines in the district have proved three profitable zones, that dividends are being paid from the second and third zones, lying at depths of 2000 to 4000 ft. on the underlie, and that the most profitable mine in Amador county today is the deepest, over 4000 ft. on the underlie. The mine was closed down in 1888 on account of fire underground, at a time when 160 stamps were being supplied with ore and the monthly dividends distributed amounted to \$48,000. The reopening by the California Ex-

level downward, and in order to expedite the work it was attacked at three points, at the 1600, 1850, and 2000-ft. levels. At the time of writing, there still remains 80 ft. of timbering to be placed in the shaft to effect its completion. In driving southward from the shaft on the 950 and 1140-ft. levels, a large amount of valuable ore has been found. This part is in fact practically a new mine, and is to be developed from the 1500 and 1600-ft. levels. Conditions are favorable for low working costs, and it is calculated that any ore above \$3.50 per ton will be profitable. The milling plant is to have a capacity of 8000 to 9000 tons per month, and should earn a profit of \$260,000 per year. It is expected that it will be ready earlier than the end of September, the date originally mentioned in the prospectus. As Mr. Loring says, the mine is situated, not in an uncivilized or uninhabited part of the world, but in the middle of a settled state which has a record of the best mining practice in the world.

A particularly bad case of blundering by engineers and queer methods on the part of company promoters is presented by the Juga (Nigeria) Tin & Power Co., which was formed four years ago as a subsidiary of the Champion Tin

LONGITUDINAL SECTION OF THE PLYMOUTH MINE, AMADOR COUNTY, CALIFORNIA.

ploration Co. was accomplished in the time originally estimated and within the amount provided for the purpose. When the bottom was reached—that is, the 1600-ft. level—exploration was started vigorously. An old winze below the 1600-ft. level was continued on the lode to the 1850-ft. level, where 334 ft. of driving proved a width of lode of 4½ ft. and an assay-value of \$6.32 per ton. The winze was then continued to 2000 ft., where a cross-cut exposed 21 ft. of ore averaging \$6.18 per ton. Driving north and south for 120 ft. exposed 7¼ ft. of lode averaging \$15.86 per ton. In this mine the second pay-zone had been entered, and with good fortune there should be 800 to 1200 ft. of profitable ore before reaching the bottom of this zone. The shaft has been turned into an incline from the 1600-ft.

Fields. At the time of flotation a report by C. G. Lush was circulated, giving the results of his sampling of 700 acres of ground, 9 ft. deep, and containing from 60c. to \$1 per cubic yard in cassiterite. The total content was figured at over 15,500 tons of cassiterite, which at \$480 per ton formed a big asset. Now comes the official statement by the board that the yield to date has been only 256 tons and that the ground contains only 360 tons more. The present directors complain of other undependable reports written by L. H. L. Huddart and A. W. Hooke, and state that it was not until July 1913, when J. J. Hunter assumed the management, that the real state of things was discovered. The method of formation of the Company was not above suspicion, for the directorates of the vendor and subsidiary companies were practically identical, and the purchase price was no less than \$480,000 in cash and 125,000 shares of \$4.80 each. These three directors have since resigned and have been lying low and saying nothing. Efforts have been made by their successors on the board to recover part at least of the purchase price, but the authorities on company law advise that legal pressure would be futile. The present chairman has uttered a sad wail about the undependableness of reports by mining engineers. There have been of course, unreliable reports

from pseudo-engineers, but I must say that many people here share the pained surprise of the chairman that two members of the profession whose names are not unknown should apparently have made such a bad break as this. It is to be hoped that they have some explanation or answer.

The report of Natomas Consolidated for the year ended December 31, 1913, has just been issued. The report seems mainly an attempt on the part of the consulting engineer, C. M. Rolker, to the London agency to justify discrepancies between the estimates made in his original report for the English investors and the results of actual operation. The salient feature in the profit and loss account is that the profit for the year, before writing off depreciation or bond discount, amounted to only \$107,841. The following sentence in the report gives the gist of the situation as regards the dredges: "On the whole the dredging results have been disappointing." On page 916 of this issue will be found an abstract of the Company's report. According to the president of the Company, as stated in Mr. Rolker's report, "The gold recovery has been about 15% less on the gross gold, and about 27% less on the net than the bore-holes indicated."

On account of the negotiations for re-financing Natomas at present pending, the following is of interest. According to the report, the current liabilities are: notes payable, \$1,578,646; accounts payable, \$1,036,071; vouchers payable, \$242,923; accrued interest, \$40,502; a total of \$2,898,142. The bonds issued are \$17,375,000, and bonds pledged, \$5,326,000; making a total of \$22,701,000. The engineering department estimates the cost of the work remaining to be done in the reclamation districts, irrigation lands, etc., at \$1,703,185, and reference is made to a note at the end of the report: "Since the above was written, general but not detailed figures have come to the writer's knowledge, from which it appears that the indicated omissions in the schedule represent something like \$1,000,000 in addition to the quoted schedule as far as the writer knows at present."

In July 1909 the president of the Natomas Consolidated approached the Hirsch Syndicate, Ltd., to procure for Natomas by January 15, 1910, \$5,000,000 to complete its dredging fleet and finish the reclamation and irrigation project. He laid before the Syndicate the report of the Natomas' general manager. The Syndicate asked for and received from W. P. Hammon, also an interested party in the property, a cable endorsing the report that the net dredging profit exceeded \$20,000,000. The consulting engineer was asked in August 1909 "to proceed to California to examine the data on which the report was based; he was not asked to re-drill the property." The report was favorable, and at the time of the flotation of the \$5,000,000 worth of the Natomas bonds, this report was published. The report just published emphasizes the facts that C. M. Rolker, as consulting engineer, relied upon Messrs. Cleaveland and Hammon for the estimated yield from the gravel, and evidently for the dredging costs also. The original report states that he depended upon agricultural experts for the value and profit to be derived from the farm lands and lands to be reclaimed. The present report says he is not an expert on reclamation. He also states that the estimate of the cost of the "new dredges were made between the Company's Californian engineers and the Yuba Construction Co. The writer did not make any estimate of the cost of the dredging or other plant."

Mr. Rolker says: "To those who may ask why the writer did not bore some test-holes to check the accuracy of the general manager's statement, the reply is given that it would have been futile and misleading to attempt to do this by a few test holes." It is hardly conceivable that the examining engineer of a property the size of the Natomas, and one involving the expenditure of \$5,000,000, would have been limited to a few holes had he desired to obtain first-hand knowledge of the ground under examination. The statement is made that when extraction results did not bear out expecta-

tions, Mr. Rolker notified F. W. Griffin, then the president of the Company, of this fact. Mr. Griffin, who was evidently surprised, "took immediate steps to satisfy himself as to the correctness of the writer's assertion." A special dredging engineer was engaged by the Company "to test this question with instructions to do check boring."

While it would have been good business had a special and competent dredge engineer been engaged in the first instance, it was hardly necessary to hire one simply to prove that the dredge recovery was not up to the estimate when the values indicated on the drill-maps furnished by the vendors, compared to actual returns from the dredges, would be sufficiently plain to establish this discrepancy.

Mr. Rolker emphasizes the fact that the gold contents indicated by the different bore tests were reduced by 15% in order to make them representative of actual extraction. The customary practice of independent engineers, familiar with the examination of dredging propositions at that time, was to reduce the value indicated in prospecting by 25%. The present report on the whole is a weak affair, and does not strengthen Mr. Rolker's position. It would seem that if his engagement was simply to go over maps and statements furnished by the vendors, and to adopt same with slight modifications, his report would have had the same technical value had he remained in his London office during the whole period. It could hardly be expected that he would correctly appraise the ground under the conditions that obtained as stated in the present report.

BUTTE, MONTANA

'SAFETY-FIRST' PRIZES.—NEW COAL MINES.—ANACONDA LEACHING PLANT.—COAL DUST FOR REVERBERATORY FURNACES.—ELM ORLU MILL.

The foreman of the Original mine in Butte, Dan P. Sullivan, is winner of the first annual prize of \$750 offered by the Anaconda company to the foreman who has the least number of serious accidents during the year. Karl P. Krueger, foreman of the West Colusa mine, won the second prize of \$250. A serious accident is considered to be one which keeps a man from work 30 days or more. The percentage is calculated on the number of man-shifts worked underground during the year under each foreman. The Company is convinced that this policy of a reward for guarding against accidents is yielding good results, and that the money spent in prizes is saved many times by the avoidance of damage suits.

The Great Northern Railway is opening a new coalfield at Windham, in Fergus county. Its old mines at Belt are nearly exhausted, and the grade of coal mined from there was never satisfactory. The new mines contain a better grade of coal, and it occurs in thicker purer seams.

The manager of the Washoe plant, E. P. Mathewson, expects the tailing leaching plant to be in operation by next spring. Excavation for the buildings is now under way, and the steel is being ordered. This leaching plant bids fair to be the most important advance of recent years in copper metallurgy.

The coal-grinding plant at Anaconda for feeding coal to the reverberatories in the form of dust will be ready for use by July 1. The furnaces are to be remodeled one at a time, so that they will be adapted to the new fuel. In addition to the important saving in fuel expense, the new method of firing will do away entirely with clinkers and ash. Credit should be given the portland cement industry for the development of this form of fuel for high-temperature furnaces.

The new 500-ton concentrating plant for the Elm Orlu mine is about ready to start. The technical crew is being employed, and June 1 is the date set for starting. Considerable interest is being shown in the operation of the new

mill, as it has evidently been the ambition of the management to have the mill as nearly perfect as possible to start with, and thus avoid the vexatious and expensive delays attendant on the usual changes and revisions. Considerable expenditure and effort were made in preliminary testing, and advantage was also taken, naturally, of the experience of the Butte & Superior mill. The ore to be treated, however, is different in important respects from that of Butte & Superior. The copper content is of commercial value and must be saved, and the iron content is not so uniformly low. The Elm Orlu is adopting the flotation equipment of the Minerals Separation company, and the plant has been installed.

AUSTIN, TEXAS

FAILURE TO PRODUCE PIG IRON FROM EAST TEXAS ORES AT A PROFIT.—HIGH FREIGHT RATES AND FOREIGN COMPETITION.
—COSTS OF PRODUCTION.

Another effort to develop the iron ores of east Texas, through the use of the state's iron-ore furnaces at Rusk, has failed. D. M. Barringer, of Philadelphia, president of the Texas Iron Association, which recently leased the furnaces at Rusk and made extensive improvements, has notified Governor Colquitt of its intention to cancel its contract and abandon its plans for manufacturing pig iron at Rusk from ores shipped from its holdings in Cass county. Notwithstanding the extent of the east Texas orebodies, the high freight rates on the raw material to the furnace, the low rates available for Birmingham pig iron, and the product of foreign furnaces have made it impossible to operate the plant profitably. The Association will lose the \$20,000 invested on improvements and repairs to the Rusk furnaces, and other large sums sunk in developing the Cass county ore-beds and in equipment for handling the ores. To attempt to operate the plant under present conditions, however, would entail an even greater loss, according to Mr. Barringer. Under the terms of the agreement with the state, the Association was given the right to cancel its contract whenever Birmingham pig iron should be less than \$11 per ton. In his letter to Mr. Colquitt announcing the Association's intention to cancel the contract, Mr. Barringer pointed out that pig iron is now \$10.50 at Birmingham, with little prospect that it will go higher. Figures have been compiled by Mr. Barringer showing that in order to operate the Rusk furnaces under present freight rates, without either loss or profit, pig iron should sell for \$18.38 per ton at common points. Pig iron from Rusk can be laid down at Houston and Marshall at an actual cost of \$17.50 per ton by taking advantage of a special freight rate to those places. Because of the low interstate freight rates, Birmingham pig iron can be laid down at Marshall and Houston for \$16, and at all other points in Texas for \$17 per ton. It is also claimed by Mr. Barringer the removal of the duty on pig iron permits the foreign product to be sold for less than \$16 per ton. In a letter to Mr. Barringer, Mr. Colquitt said: "In your statements, you show the cost of producing pig iron at Rusk, which you estimate at \$17.38 per ton, over \$6 which, according to your figures, is cost of freight on the raw materials to the furnace. One of the principal reasons you give for not being able to operate the furnace is high rates fixed by the Texas Railroad Commission as compared with the rates for similar service on raw materials to Birmingham. I did all I could to secure a lower rate for you. One of the purposes of the administration in leasing this property to you was the hope it had of demonstrating the value of east Texas iron ore. I believe, if this could be done, that there would be a large sum of money invested in east Texas for the development of this industry, and I am very sorry that the commission and the railroads did not give you a rate which would encourage the development of the enormous wealth dormant in east Texas which has so long remained undeveloped."

PORCUPINE, ONTARIO

PROSPECTS OF THE DISTRICT.—DEVELOPMENTS IN THE PORCUPINE CROWN.—MCINTYRE, NORTH THOMPSON, ACME, HOLLINGER, DOME, AND PORCUPINE GOLD MINES.

Conditions in Porcupine continue to improve, and indications point to the coming season being one of great activity. The older properties are developing well and giving excellent results, and several new properties which are being opened show considerable promise. The main centre of activity is in the Pearl Lake section, where the greatest distribution of profitable veins in the Porcupine district seems to occur.

The Porcupine Crown has been in the limelight recently on account of the rapid decline in the stock from about \$1.30 to 80c. per share. The chief reason for this decline seems to be the general impression that the vein has been cut off by a fault below the 400-ft. level, and that the management has not yet succeeded in finding it, although considerable development with this end in view has been accomplished. As a matter of fact, the position of the Company is much better than is generally believed. In the underground workings, there are two ore-shoots known as the north and south shoots. The former is narrower than the south shoot and not of so high grade. On the 400-ft. level, it was found to be much shorter than at 300 ft. A winze was sunk to the 500-ft. level, and the vein was found to dip out of the winze at 450 ft. It is understood that from the 500-ft. level a cross-cut was driven to try and find the vein, but was not successful. Operations were then resumed at the 450-ft. level, where a drift is now being run on the vein. On the south shoot, which is much wider and larger than the other, the vein at 400 ft. is approximately the same as on the upper levels. A drift is being driven to the southern boundary of the shoot, and when this is finished a winze will be sunk on the ore. So far there is no reason to expect any sudden change in this shoot below the 400-ft. level. There is, however, a fault at the southern boundary of the south shoot, the existence of which has been known since the early days of the property. Diamond-drill holes were bored south of the fault, and the results of this work indicated the continuation of the vein. A considerable amount of development has been done on this portion of the property, but so far has not been successful in developing any commercial ore. The possibilities are, however, by no means exhausted. In March the production was over \$80,000, and costs were \$4.60 per ton. This production is considerably in excess of the amount necessary to pay the dividend.

Results from the McIntyre mine have been satisfactory, and during March the mill treated 4325 tons averaging \$12.68 per ton, and made a recovery of 97.8%. Shipments of bullion for the month were valued at \$52,661. During the past year a total of 4171 ft. of development was done, and the ore available for stoping is estimated at \$1,245,000. Gold production to date amounts to \$400,868. The management hopes to increase the capacity of the mill, and additional machinery is being installed. The cross-cut under Pearl lake, on the 600-ft. level of the Pearl Lake shaft, had to be abandoned on account of the dangerous condition of the ground.

On the North Thompson, which is under control of the Huronian Belt Syndicate, the shaft has reached a depth of 90 ft. At this point the vein is between 4 and 5 ft. wide, and is said to carry satisfactory gold content. It is also reported that good results have been obtained in the deep diamond-drill holes.

If development on the Acme gold mine continues to be as satisfactory in the future as it has been in the past, the indications are that this property will develop into a large

producing mine and should be nearly as large as the Hollinger. It is altogether probable that the Company will eventually be amalgamated with the Hollinger, as it is controlled by the same people, and some of its operations are on the extensions of Hollinger veins. Thirteen drills are at present being worked, and as soon as more power is available this number will be increased. It is understood that the intention of the owners is to develop the property to a point where they have sufficient ore in sight to justify them in asking a substantial price for it.

The Hollinger mine is operating 43 drills, and has not sufficient air capacity to permit of gaining any substantial reserve of broken ore in the stopes. It is said that the present reserve of broken ore amounts to only about 12,000 tons.

Good progress is being made on the new mill at the Dome and this should be in operation by the end of May. The annual meeting will be held at Toronto on May 26, and it is understood that a full and detailed report will be submitted. The March production shows a bullion recovery of \$87,657 from 14,970 tons of ore having an average value of \$5.85 per ton.

Arrangements have finally been made for the reopening of the Porcupine Gold property, formerly known as the Vipond. A new company, known as the Porcupine Vipond Mines, Ltd., with a capital of \$1,500,000 in shares of \$1 par value, is purchasing the property of the Porcupine Gold Mines, Ltd., which has a capital of \$2,000,000, for 750,000 shares in the former Company, which will be divided among the present shareholders of the Porcupine Gold Mines, Ltd., on the basis of three shares in the new Company for eight shares in the old Company. The new Company has also underwritten 300,000 shares of treasury stock at 30c. per share, leaving 450,000 shares in the treasury. The \$90,000 realized from the sale of treasury shares is estimated to be sufficient to pay off the debts of the Company and to provide a cyanide plant which is absolutely essential to profitable operation and treatment of the ore.

NEW YORK

GRANBY'S NEW SMELTER.—UTAH METAL MINING CO.—BUTTE & SUPERIOR.—MICHIGAN COPPER MINES.—AMERICAN INSTITUTE OF MINING ENGINEERS' MEETING.

The shareholders of Granby have voted to borrow \$3,000,000, as needed, for additional working capital in its largely increased operations. At Anyox (Hidden Creek district) two of the smelting furnaces have been blown in, and a third is ready but has not been started, as difficulties in the mechanical operation of the converters and crane have rendered the converters incapable of handling all the matte produced. Smelting operations have been satisfactory, and it is reported that experience shows that pyrite smelting can be practised, and the coke consumption will be less than one-half that originally expected.

The Utah Metal Mining Co. is being reorganized, and the new Company will have a capital of \$500,000 in \$1 shares. Of these, there will be issued 396,176 shares to take up the outstanding shares of the old Company, on the basis of one of the new shares for four old shares, plus a payment of 10c. per share on the old stock. It is stated that, of the new shares, 120,000 will be issued to take care of the floating debt. Just how this will be accomplished is not clear, since only 103,000 shares will be left in the treasury when the exchange is completed; nor is it clear how these can be made to provide 134,000. It is hard to determine the price of the shares, though, since there have been no recent transactions in them. The story of this Company is merely another page in the history which began with the driving of the Sutro adit on the Comstock, and the moral is that long adits driven for

drainage and exploration purposes are not good investments, for they rarely develop much of value, and by the time they are completed the mining boom which caused them to be started is commonly past. While speaking of companies in the Bingham district it may be noted that W. O. Allison has begun a campaign to get control of the Ohio away from F. A. Heinze. Considering its modest production of a little over 500,000 lb. of copper per month, the Ohio makes a tremendous amount of stir in the world.

The Butte & Superior report for the first quarter of this year makes a fair showing. The Company's interests are said to be negotiating for the Success mine, in the Coeur d'Alene region, Idaho.

Calumet & Hecla has declared a quarterly dividend of \$5 per share, instead of the \$10 which used to be the rule before the strike last year. The Osceola Consolidated has made a good recovery from the strike and is now crushing at the rate of 100,000 tons per month, its normal capacity. The ore now being milled yields a little over 11 lb. of copper per ton. The Allouez now has 330 men at work and is mining 1000 tons per day. As the labor supply in the Lake district is now good, it is expected that the working force will be considerably increased soon. The New Arcadian shaft is to be continued from the 750 down to the 900-ft. level. The long record of unsuccessful work of the Arcadian makes the persistence of the management worthy of admiration. The Isle Royale is increasing its output, and should be producing 2600 tons per day soon.

The New York section of the American Institute of Mining Engineers held its annual business meeting on May 21. Departing from the usual practice, the meeting was held at Browne's Chop House instead of at the Institute headquarters. The usual reports of officers were presented, and then the section officers for next year were elected, as follows: L. W. Francis, chairman; Willard S. Morse, vice-chairman; P. L. Mosman, treasurer; T. T. Read, secretary. Following the business meeting, a beefsteak supper was held, over which E. F. Roeber presided. Dr. Kohlbeck, who has come to this country to be present at the celebration of the fiftieth anniversary of the Columbia School of Mines, was the first speaker of the evening and made a brief address, in which he expressed his pleasure at being present, and complimented the mining profession of America on the wonderful growth which has resulted in so short a period in this country. The next speaker was T. A. Rickard, who represents the Royal School of Mines of London at the Columbia celebration, who spoke of the influence of the Cornishmen in the development of the mining industry in America and throughout the world. B. B. Thayer, the president of the Institute, was next called upon, and after expressing his pleasure at the successful meeting, stated that he relied upon his friend, John C. Montgomery, to tell German stories for him. Mr. Montgomery related amusing anecdotes of the early days of mining in America, the absence of the German accent in his stories being marked. James F. Kemp was next called upon to speak of the influence of Germany on geology, and kept his listeners in laughter by an account of his student experiences in Germany and the rendition of some German mining songs with a faultless Milesian accent. Henry S. Drinker, the president of Lehigh University, spoke of early days in the Institute, he being the only charter member of the Institute present. In addition to referring to the early days of mining in this country, Dr. Drinker also told of his boyhood in China and Japan and the influence of Americans in the early development of those countries. Charles F. Chandler, emeritus professor of chemistry in Columbia, and the only one of the original faculty of the School of Mines present, gave a most interesting account of the difficulties of early development of the School and related amusing anecdotes from his wealth of experiences gained during his long period of service as dean of the School of Mines at Columbia.

General Mining News

ALASKA

JUNEAU

The Alaska Mexican, Treadwell, and United companies paid dividends No. 74, 106, and 27, of 20c., \$1, and 20c. per share respectively on May 28. The outputs of these properties in April were as follows:

| | Alaska Mexican. | Alaska Treadwell. | Alaska United. |
|-------------------------------|--------------------|----------------------|-------------------|
| Development feet | 6 | 50 | 1,668 |
| Stock of broken ore, tons.... | 14,581 | 52,793 | 4,671 |
| Stamps working | 120 | 540 | 240 |
| Ore crushed, tons | 19,845 | 80,724 | 36,687 |
| Concentrate produced, tons. | 353 | 1,584 | 794 |
| Gold by amalgamation..... | \$22,830 | \$104,624 | \$38,811 |
| Gold by cyanidation..... | 24,116 | 84,421 | 34,093 |
| Realizable value | 46,477 | 187,155 | 72,175 |
| Net profit | 18,873 | 103,952 | 13,317 |

Considerable work was also done by the Mexican company in the United company's 700 Ft. Claim for the purpose of handling Mexican ore through the central shaft. The Treadwell company also did a good deal of work in the 700 Ft. Claim for the benefit of the Mexican, United, and Treadwell companies, the cost of which is charged out proportionately.

ARIZONA

COCHISE COUNTY

A 200-ton per hour rock-crusher plant is being assembled at the Junction shaft of the Calumet & Arizona mine. It should be complete by July. On Sacramento hill at Bisbee, the Copper Queen company has three drills at work. Creditors of the Tombstone Consolidated Mining Co. have asked that the property be sold. Engineers of the Copper Queen company have examined the mine, and the Company will probably bid for it. The Murphy interests may also enter the bidding. In the Shattuck-Arizona mine, silicious gold ore at 300 ft. assays from \$8 to \$170 per ton. At 400 ft., 10 ft. of oxidized ore contains 18% copper. Rich gold ore is also being opened at 200 ft. Work at 300 ft. is promising.

GILA COUNTY

(Special Correspondence.)—Riveting has been started at the Inspiration concentrating building with 32 men. In all, the American Bridge Co. will have to drive 140,000 rivets. The forge shop at the mill is nearly finished, and several machines are already working. The Oscar Daniels Co. has 40 men at work at the smelter site. The concentrate receiving pocket is completed, and steel is being erected on the 12,000-ton bedding bins, also on the boiler house of the power-plant, which is to contain seven units of Stirling boilers, using waste heat from the reverberatory furnaces. Excavations are completed for the two oil-storage tanks, situated on the top of the hill just to the east of the power-plant site. These tanks will have a combined capacity of 30,000 bbl., or nearly 1,000,000 gallons.

Miami, May 22.

CALIFORNIA

During the first 4½ months of its operations, the State Compensation Insurance Fund has written premiums aggregating \$350,000. On January 1, the estimate of probable business for the entire first year was \$250,000. These premiums of \$350,000 represent an estimated annual payroll of \$50,000,000, and about 55,000 workers are thus affected by insurance in the state fund. During the period referred to, the number of accidents reported and covered by these fund policies was 980. Of this number there were only four cases necessary to be submitted

to the Industrial Accident Commission for adjudication. In three of these, hearings were necessary to establish the extent of disability or extent of dependency; and one claim was disputed as to its validity, in which case it was proved that injury was not sustained in the service of the employer. This means that out of every one hundred claims for compensation, over 99.5% have been handled promptly, and to the entire satisfaction of the workers, and that less than 0.5% of the cases have been submitted for hearing.

AMADOR COUNTY

It is said that an engineer representing Eastern capital has been examining the old Eureka mine (Hetty Green property) at Sutter Creek. A large tonnage of profitable ore is said to have been opened years ago.

BUTTE COUNTY

Rich gold ore has been opened in the Little Joe mine near Hurleton, in which Oroville people are interested.

LASSEN COUNTY

A mineral belt near Doyle is said to have great possibilities for profitable working.

MERCED COUNTY

(Special Correspondence.)—The Yosemite Dredging & Mining Co., operating at Snelling, on the Merced river, has just completed and started a new dredge. It was constructed by the Yuba Construction Co. from parts of the old one and a

NEW DREDGE OF THE YOSEMITE DREDGING & MINING COMPANY.

considerable amount of new material. The buckets are of 3.75-cu. ft. capacity, and the gravel is disintegrated by a shaking screen. Everything is driven by electric motors.

Snelling, May 17.

NEVADA COUNTY

The Oustomah shaft is being deepened from the 1050-ft. level. At 400 ft. the west cross-cut has cut a rich shoot. An option on the Murchie mine, near Nevada City, has been acquired by H. W. Miller of New York. The property has been mixed up with the Myers-Wisner swindle, and is in debt. Henry Fitter is to be in charge. Work has been resumed at the Gaston mine. The Cassidy mine is to be unwatered, and George St. John, of the Alaska mine, Sierra county, is head of a new company to reopen the property. A contract for the construction of a 15,000,000 gal. reservoir has been let by the trustees of Nevada City. This will be constructed in the old McCutchan hydraulic diggings near Canada hill. The water supply will come from Little Deer creek, this water right having been acquired by the city many years ago.

PLACER COUNTY

The Occidental and Weber properties near Iowa hill are to be opened by an adit by the McGleachin company. A. Rose is in charge of the work.

SHASTA COUNTY

The Balaklala mine is producing 300 tons of copper ore per day, most of which is going to the Mason Valley company's smelter at Thompson. At the mine and idle Coram smelter 145 men are employed. No more experiments with the Hall process will be made at the smelter, according to the general manager, Frank M. Leland; but will be tried at the smelter at Garfield, Utah.

SIERRA COUNTY

Two shifts are working at the White Bear gravel mine. A large body of quartz has been opened in the Monarch mine, and 10 stamps are to be added to the mill. Dan McGonigal is manager.

TRINITY COUNTY

(Special Correspondence.)—W. A. Boyce, who has a bond and option on the Ozark mine, expects to have his new arrastre ready for work about May 25. He has several tons of good ore on the dump and plenty in sight. Mr. Boyce expects the results will be good enough to justify him in taking over the property, which has been practically idle for several years, but has produced some high-grade ore, and is considered a good property. Jack McGinn discovered a small rich vein, in Rich gulch, which proved to be on ground belonging to H. L. Knowles of Helena. He expects to open it soon. Charles Myers is making good progress on his cross-cut adit, which will cut his orebody at considerable depth. This is a promising prospect. A drift from the lower adit on the Golden Chest has reached the ore-shoot beneath the old workings, and cut ore which shows free gold and high-grade galena. The vein is 4 ft. wide and improving. T. J. Rochford is in charge. The Enterprise mine is employing 12 men. The 10-stamp mill is running full time on good ore, and there is plenty of it in sight. R. A. Skinner is in charge.

Helena, May 10.

The reports of the Trinity Gold Mining & Reduction Co. and the Trinity Consolidated Hydraulic Mining Co. for the year ended November 30, 1913, have just been published. The reports of the general manager, at Douglas City, D. W. Shanks, contains the following information, the first named being covered first: Owing to lack of funds to do further drilling, development was stopped about the end of March 1913. The orebody found at a depth of 150 ft. by drilling, and opened later by drifts, is 8 ft. wide and 60 ft. long, and dips at an angle of 70° from the horizontal. The drill had passed through the richest part, assaying \$34, but 10 ft. away the value is only \$10, and farther on \$5 per ton. Results of drilling prove that other bodies of sulphide ore exist, and large shoots of such ore should be developed. There are outcrops of oxidized ore in the gulches of the property. The Headlight orebody is similar to the copper deposits of Shasta county. Various processes have been tested to treat the sulphide ores, but they failed to give commercial results. The mill was built for oxidized ore, but will not treat these ores. Owing to the presence of copper in the ore, cyaniding is unsuitable. There is a large tonnage of ore opened averaging 0.75 to 1% copper, and \$4.50 per ton in gold and silver. Power was sold during the year to the Alta Bert Dredging Co., near Trinity Center, and other small consumers. As soon as the snow has melted on the property, it will be examined by an English mining engineer. After this report is complete, and those on ore treatment from the metallurgists engaged, a plan for providing funds for future work will be formulated. Development will cost \$25,000, according to the president, Henry W. Miller, and plant remodeling may be only \$50,000. There was no revenue from the mill in 1913, it being shut down. Gross earnings from electric power, etc., were \$5175, and there was a deficit of \$12,455 on mine operating account. The surplus at the end of November 1913 was \$78,598, and the previous term \$104,797. Assets include a 40-stamp mill, hydro-electric plant, 200-ton cyanide plant, buildings, tramway, etc., worth \$177,128; other equipment, \$12,132, and supplies, \$7350.

Operations at the gravel mines of the Trinity Consolidated company were, in common with others in California, reduced on account of shortage of water. A large body of clay also interfered with sluicing at the Union Hill mine. It required powder to loosen it before the water would cut it out. Results by hydraulicking at the three properties were as follows:

| | Brown. | Hupp. | Union Hill. |
|---|--------|--------|-------------|
| Gravel moved, cubic yards..... | 31,920 | 60,000 | 326,481 |
| Gravel moved, cubic yards per day | 1,850 | 1,900 | 4,285 |
| Water, miner's inches | | 62,500 | 189,000 |
| Duty per inch, cubic yards..... | | 0.96 | 1.60 |
| Value per yard, cents..... | 14.8 | 19.3 | 5.73 |
| Operating cost per yard, cents... | 10.7 | 9.3 | 3.00 |
| Total value of gold from three mines..... | | | \$35,414 |
| Average operating cost, cents per cubic yard..... | | | 6.0 |
| Average total cost, cents per cubic yard..... | | | 7.7 |
| Operating profit | | | \$ 3,087 |
| Bond and borrowed money interest..... | | | 14,063 |
| Deficit for year..... | | | 10,976 |

A large deposit of gravel owned by the Company, over which water for the Union Hill mine is conveyed, was given a preliminary examination, and pannings averaged 5c. per yard. This could be cheaply worked under the pressure of 193 lb., and the tailing discharged into the Trinity river. Only the gravel owned by the Lagrange company and that at Dut-ton creek in Trinity county are larger than this deposit.

COLORADO

LAKE COUNTY (LEADVILLE)

The 'down-town' group of mines at Leadville, which have been flooded since 1896, are to be unwatered, Jesse McDonald, ex-governor of the state, having called for bids for the pumping plant. This will cost about \$100,000.

SAN MIGUEL COUNTY

At a depth of 300 ft., \$15 to \$25 ore has been opened in the Fourth of July and Nancy Hanks claims in the old Saw-pit district. During April the Tomboy mill treated 12,000 tons of ore yielding \$39,500 and \$39,500 from 960 tons of concentrate shipped. The estimated profit, including \$3050 from the tramway company, was \$30,050. The Humboldt mine, near the Smuggler-Union in the Telluride district, has been optioned to the Breitung Mining Co. of New York. It was recently examined by F. G. Farish, and is to be checked by R. E. Cranston. Reserves are estimated at 104,261 tons, worth \$1,860,454.

TELLER COUNTY (CRIPPLE CREEK)

A car of coarse rock and one of screenings from Korff, Heith, and Bruington, lessees on the Isabella property, averaged \$30 and \$55.40 per ton respectively. This lease produces from 9 to 12 cars of ore per month. Bailing water with two buckets under cages in the Granite company's Gold Coin shaft, 950,000 gal. was removed in 12 hours recently, recovering No. 11 level. The properties of this Company produced 2600 tons of \$25 ore in April. Probably the Portland mill on Battle mountain will receive custom ore for treatment.

IDAHO

BLAINE COUNTY

The Wilbert Mining Co.'s report for the ten months ended May 1, 1914, shows that there is 10,000 tons of ore in the old stope, No. 2, and the Quarry workings; and 15,000 tons between No. 3 and 4 levels. Owing to the low price of lead, ore production was stopped on January 15. During the period, the mill treated 11,193 tons of ore assaying 30.5% lead and 2.69 oz. silver, producing 5301 tons of concentrate containing 5,546,118 lb. lead and 24,080 oz. silver. Recoveries were 81.23 and 79.98% of the lead and silver respectively. The revenue was \$160,463, and net profit \$29,733. Development is to be continued.

SHOSHONE COUNTY

Copper ore from the new North Fork district is to be transported 18 miles on flat-boats down the North Fork river to Prichard, where it will be loaded on railroad cars for the smelters, according to *The Wardner News*. The ore is high grade, up to \$100 per ton in copper and gold. The first

shipments will be from the Mayday group owned by J. Stout, E. Williams, and C. Feehan. Another well developed property is owned by G. Morrison, S. Murray, G. Allen, B. Kincaid, and J. Wright. Fernan Bros. have promising claims. This new mineral belt has extended the Coeur d'Alene district 20 miles farther north. Beyond this prospectors have not done any work.

The holdings of the Aeolian Consolidated Copper Mining Co., Marguerite Mining Co., and others, totaling 32 copper claims and fractions, have been acquired by the Columbia Copper Co. This has a capital of \$2,500,000, and is controlled by Idaho, Spokane, and French people. The National Copper Co.'s lower adit runs through the claims and will probably be used in mining operations.

MICHIGAN

Michigan participated in the general increase in coal production in 1913, mining 1,231,786 short tons, valued at \$2,455,227, according to figures compiled by E. W. Parker, of the U. S. Geological Survey, in cooperation with the State Geological Survey. The increase over 1912 was 25,556 tons in quantity and \$55,776 in value.

HOUGHTON COUNTY

Between No. 1 and 2 regrinding plants, the Calumet & Hecla company is preparing to erect the first unit of a large leaching plant. There will be eight vats of 1000-ton capacity each. A recovery of 70% is expected by the metallurgist, Mr. Benedict.

MONTANA

LEWIS AND CLARK COUNTY

The U. S. Assay Office at Helena has been the subject of a good deal of discussion in Congress, some senators alleging that it is being maintained for large mine operators. This is not so, as 96.7% of the depositors of bullion returned less than \$10,000 each. Since 1903 there have been 10,270 deposits, valued at \$21,455,654.

LINCOLN COUNTY

A bond has been secured on about 2000 acres of placer ground on Big Cherry creek, in the Libby district. The property is owned by Howard Bros., and the new men interested are J. E. L. St. Clere, Charles L. Monsch, and C. A. Chapman of Los Angeles and E. E. Mellander, of London. Prospecting has been under way for several weeks.

SILVERBOW COUNTY

The Butte & Superior Copper Co. reports as follows for the first quarter of 1914:

| | |
|--|------------|
| Ore milled, dry tons | 97,590 |
| Average zinc content, per cent. | 18.546 |
| Average silver content, ounces per ton | 10.3913 |
| Zinc concentrate produced, pounds | 63,560,288 |
| Ratio of concentration, tons of ore producing 1 ton of concentrate | 3.07 |
| Average zinc in concentrate, per cent. | 51.73 |
| Average silver in concentrate, ounces per ton | 26.41 |
| Mill recovery, per cent. | 90.84 |
| Cost of mining, per ton | \$3.244 |
| Cost of milling, per ton | 2.175 |
| Total cost | 5.45 |

There was also produced 887 tons of lead concentrate assaying 49.24% lead and 45.34 oz. silver. The net value of all products was \$869,216, and net operating profits \$337,242. Development in the mine totaled 4361 ft. and was charged to operation. A good development was made on the 1400-ft. level of the Black Rock and Four Johns claims. At the end of March the cash on hand amounted to \$810,467, and the directors have decided to start the payment of quarterly dividends immediately.

The North Butte mine is reported as being in excellent

shape. At 2400 and 2600 ft. the Edith May vein shows improvement. At 2400 ft. the Snowball vein is opening well.

The Anaconda company has ordered two additional 150-hp. induction motors from the General Electric Co. The East Butte company will install 35-hp. and 100-hp. induction motors recently ordered from the same firm.

NEVADA

The U. S. Geological Survey is planning to continue exploratory drilling for potash in the West during the coming season, and will probably have the work done by contract under the direct supervision of the Survey, if favorable bids can be obtained for sinking to at least 1200 and possibly 2000 ft. Among other plans for the potash search for this year, the Survey expects to sink one or more deep wells in the Black Rock desert of this state. The site proposed for further work by the Survey lies in the 'sink' or low part of the desert, which was one of the principal arms of the prehistoric Lake Lahontan. This is northeast of Gerlach, and only four or five miles from the main line of the Western Pacific railway, north of a station called Trego in Washoe county. Bids for the drilling contract will be called for at an early date. Conditions seem favorable for the occurrence within the desert of a well defined saline deposit.

CHURCHILL COUNTY

During April the Nevada Hills mill treated 4820 tons of ore averaging \$8.90 per ton and yielding a net return of \$9891. The total resources of the Company are worth \$218,199, with no liabilities.

ESMERALDA COUNTY

After June 1 the Jumbo Extension company will cease sending ore to the Bonnie Claire mill, south of Goldfield, and ship to the Goldfield Consolidated mill. The respective milling costs are \$3.16 and \$3 per ton. Good ore is being mined at 200 ft. in the Sandstorm-Kendall mine.

HUMBOLDT COUNTY

The National Mines Co. is increasing its working force. P. G. Harrison is manager. High-grade ore is being mined by the Heines-Baldwin lessees. The Indian Valley vein has been cut in a lower level of the Highland Mary. In the Buckskin National, the high-grade streak is now 4 to 5 in. wide, averaging \$40 per pound.

STORIE COUNTY

A. M. Walsh, of the United Comstock Pumping Association; T. E. McCormick, of the Ophir and Consolidated Virginia mining companies; James M. Leonard, of the Virginia & Gold Hill Water Co., and T. S. Higgins, foreman for the last Company, inspected the Sutro adit and its branches on May 19, according to *The Virginia Chronicle*. The main adit throughout its full length was found in first-class condition, many new sets of timbers having been placed during the past year. The engineers then went through the south lateral branch of the adit to the Alta shaft connecting drift, and found the timbering in as good condition as in the main adit. The Alta drift, which was recently reopened and repaired, and a new drain constructed, was also found to be in a most satisfactory condition. At the Crown Point connection with the south lateral, the water being pumped from the Gold Hill mines by the Sturges management at the joint Crown Point-Belcher incline, is being discharged into the adit drains, and is being handled with ease and with ample capacity for a much greater volume of water from that part of the lode. The Ward shaft connecting drift was also carefully inspected from the south lateral adit to the adit level of the Ward shaft, and it was found to be in a good state of preservation. The officials next returned to the junction, and examined the north lateral branch to the Ophir connecting drift, which was found in splendid condition. The ventilation throughout the adit was found

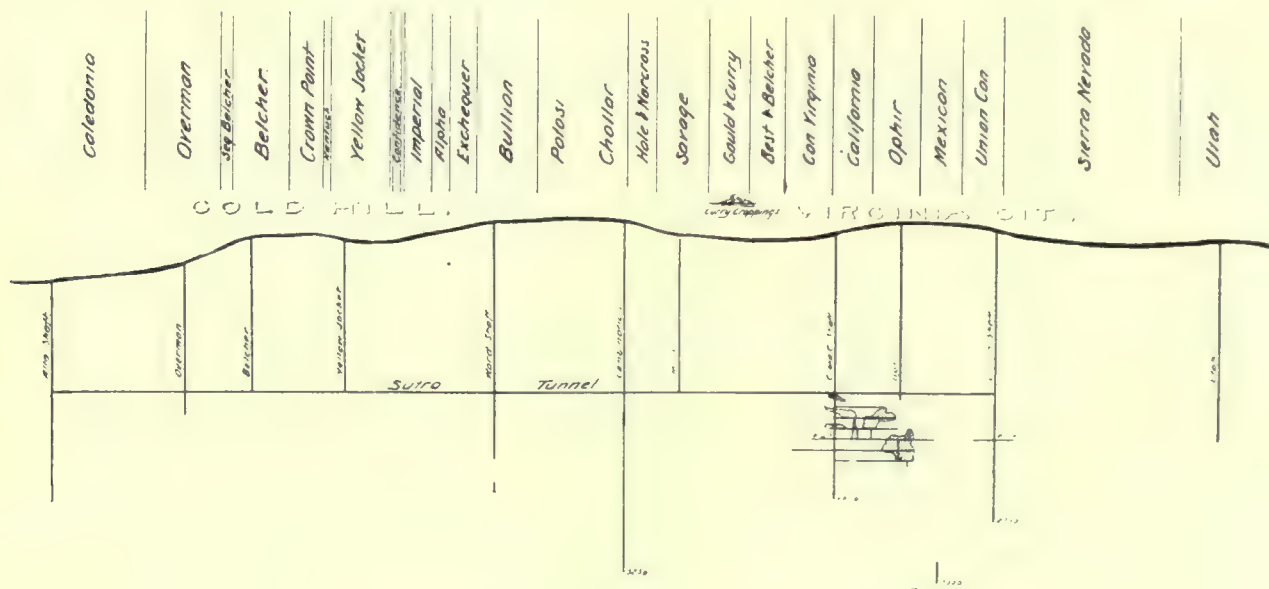

to be good, with all the air connections working satisfactorily. They then returned to the surface through the C. & C. shaft. It is of interest to know that the United Comstock Pumping Association is now pumping into the Sutro adit at the C. & C. shaft, a volume of water that is estimated at about 4,000,000 gal. per day; and at Gold Hill the mines are discharging nearly 1,500,000 gal. additional per day, making a total of 5,500,000 gal. per day that is being removed through the adit. The adit is thus performing most effectively one of its primary duties, and is a most important feature of the deep-level drainage of the Comstock lode.

During the past week, 237 tons of \$15.55 ore was extracted

or an average of \$4.01 per ton, compared with 1,528,923 tons, \$6,600,953 in bullion, and an average of \$4.31 in 1912. In 1913 a considerable tonnage was mined by 'glory-holing', and by caving above the 700-ft. level.

LAWRENCE COUNTY

The Miners' Union building at Lead, of four stories, 75 by 125 ft. in area, and erected some years ago for the union miners, was sold last week to Charles H. Moyer for \$43,992. Judgments were held against the Lead City Miners' Union by the Butte City Miners' Union and the Western Federation of Miners. Mr. Moyer represented the two last organizations. The building originally cost about \$100,000.

SECTION OF THE COMSTOCK LOPE, SHOWING SUTRO TUNNEL.

from 2350 and 2400 ft. in the Ophir mine. Forty-six feet below the 2500-ft. level the Sierra Nevada has 30 in. of \$60 ore. The Yellow Jacket mill treated 1148 tons of ore, half from the Crown Point mine and the balance from the Jacket dump. The Mexican company will pay a dividend of 75c. per share, totaling \$141,750 on June 4.

SOUTH DAKOTA

The value of the gold, silver, copper, and lead produced in South Dakota in 1913, as reported from 30 productive mines, 10 of which were placers, amounted to \$7,424,333, compared with the record yield of \$8,019,370 in 1912, according to Charles W. Henderson, of the U. S. Geological Survey. This state has produced in the 37 years from 1876 to 1913, inclusive, \$177,954,132 in gold and 5,656,027 fine ounces of silver, with a commercial value of \$4,115,991, a total of \$182,070,123. The gold output in 1913 was 354,071 fine ounces, valued at \$7,319,294, nearly 99% of the total value. The decrease in gold for the year was 27,674 fine ounces in quantity and \$572,076 in value. The production of silver also decreased, from 206,460 to 172,702 fine ounces. Smelting ore from South Dakota in 1913 contained 10,205 lb. of lead, against 22,845 lb. in 1912. The output of placer gold decreased from 664 oz. in 1912 to 67 oz. in 1913. A total of 1,899,167 short tons of ore was mined and treated in 1913, compared with 1,901,726 tons in 1912. Of this total, 1,895,445 tons was treated in the mills of the state, yielding \$7,219,399 in gold and 163,359 fine ounces of silver, with an average recovery per ton of \$3.81 in gold and of 5.2c. in silver. The output of smelting ore, 3722 tons, averaged 1.28 oz. of gold and 2.51 oz. of silver per ton. The Homestake mine and mills were operated continuously throughout the year and made an output of 1,540,961 tons of ore, which yielded bullion of the value of \$6,186,652,

UTAH

BEAVER COUNTY

The annual report of the Horn Silver Mining Co., W. H. Hendrickson, manager, contains the following information: The property is in good condition. Development was hindered by the bad order of the shaft at No. 9 and 11 levels. This and other mine work cost \$25,000. The revenue from 25,183 tons of lead-zinc ore tailing, ore dumps, concentrate, and slag was \$149,380. The profit was \$2930. It is hoped that the old tailing can be profitably treated. There has been a rush to a new goldfield in this county, but little has been published regarding its prospects so far.

SALT LAKE COUNTY

Uranium ore amounting to 600 tons has been shipped to Europe during the last twelve months by David Taylor & Co., of Salt Lake City, buyers of rare metal ores. The ore averages 2% uranium, and is sampled in Denver prior to export. Cost of handling the ore from the Pack Creek mines to Europe is about \$40 per ton.

WASHINGTON

OKANOGAN COUNTY

(Special Correspondence.)—Motor-trucks are now hauling ore from the Peacock mine to the Great Northern railway at Okanogan, from where it will be sent to smelters. A 50-ton mill may be built. The Reco mine is producing gold ore. A claim producing wolfram near Cathedral peak has been bonded for \$20,000. The United Mines has been organized with a capital of 1,200,000 \$1 shares, to operate the Owaseo, Golden Chariot, Portal, and Oro de Madre groups of claims on Kruger mountain. The last mine produces a smelting

ore containing 2 to 4% copper and \$8 to \$60 gold, and a good percentage of iron. From 50 to 100 tons of ore per day will probably be shipped over the new road to Oroville on the Great Northern railway. Senator Jonathan Bourne, of Portland, Oregon, may construct an electric railway from the Ruby district to Okanogan, on the Victoria, Vancouver & Eastern line, to develop the mines properly. The Duluth-Toroda Mining Co.'s claims have been purchased at a sheriff's sale by Arthur H. Perkins. Important work is under way at the Chesaw, Reco, Lucky Strike, Gold Leaf, and Phil Sheridan mines.

Chesaw, May 14.

PEND OREILLE COUNTY

(Special Correspondence.)—The Gray Copper Mining Co. has opened ore containing \$1.56 silver, \$12.50 gold, and \$19.80 copper per ton.

Usk, May 15.

CANADA

MANITOBA

The gold yield of Canadian mines last year was \$16,216,131, to which this province contributed very little, according to *The Rice Lake Gold Miner*. This is published at Winnipeg and deals with mining in the Rice Lake district, which is 100 miles northeast of that town and is the starting point for several different routes. Properties being prospected are the Goldfield, Winnipeg, Gabrielle, the first staked; Rice Lake, Emperor, Manitoba, and others. A 5-stamp mill will be erected at the Big Four during the summer. About 1000 claims have been staked, and wide veins of good value are said to be opened in several properties.

ONTARIO

Under the McKinley-Darragh company's option, the Jupiter mine at Porcupine is developing well. At 300 ft. the ore-shoot is 300 ft. long, 42 in. wide, and averaging \$15 per ton. From the winze to 400 ft. a cross-cut has cut 5 ft. of \$6 ore. During the first quarter of 1914 the McKinley-Darragh mine, at Cobalt, produced 411,954 oz. silver. The mill is now treating 220 tons per day. At the Miller Lake O'Brien mine, at Gowganda, 20 tons of 5000-oz. silver ore has been mined from the 250 and 300-ft. levels.

COSTA RICA

The Abangarez Gold Fields company treated 6755 tons of ore in March, yielding \$24,896 at a cost of \$47,428.

KOREA

The Oriental Consolidated mills produced \$155,770 in April.

PERU

The Peruvian Exploration Co. at present has a working staff of nearly 300 men, with fifteen Californians and Canadians with expert knowledge of hydraulic operations. About 1500 'cargos' of machinery (250 lb. equal 1 cargo) have been delivered on the ground, and 3000 more have reached Cerro de Pasco. Raymond McCune returned from the property to Lima on April 25. He came from New York to consult with his men and decide on future policy of working, and it has been decided to install a central electric plant with an ultimate capacity of 2000 hp., which for the time being will be limited to 600 hp. Hydraulic operations, it is hoped, will commence in the fall of the present year with 10,000 cu. yd. per day of 24 hours. The point chosen for this installation is Chapampet, and operating from this central station there will be at least five different points of working with hydraulic elevators capable of a total daily production of 50,000 cu. yd. The costs are estimated not to exceed 6c. per cubic yard. The gravel averages 81c. per yard. Work has just been commenced on the power ditch, and Mr. McCune is returning to New York to place orders for further equipment. He will return to Peru in about three months.

PHILIPPINE ISLANDS

Gold mining is very promising. The ore mined assays from ₱20 to ₱50 and the cost of mining and milling is about ₱12 per ton. Dredging offers a great field for future development. There are hundreds of square miles of alluvium which contain from 15 to 30 centavos (7 to 15c.) in gold which are as yet untouched. The placer ground being worked at present yields from 30 centavos to ₱1. No silver ore is mined separately. There are a few silver-bearing galena deposits in various parts of the Islands, but they are small and irregular, and have never been profitably worked.

The following statistics¹ of mineral production in the Philippine Islands for the year 1913 have been compiled by the division of mines of the Bureau of Science:

| | 1912. | | 1913. | |
|------------------------------|---------|-------------------|------------------|-------------------|
| | Quan. | Value. | Quan. | Value. |
| Metallic: | | | | |
| Iron, metric tons..... | 141 | ₱ 49,272 | 227 | ₱ 64,471 |
| Silver, fine oz..... | 7,121 | 8,664 | (²) | (²) |
| Gold, fine oz..... | 27,582 | 1,140,424 | 42,011 | 1,736,724 |
| Non-Metallic: | | | | |
| Coal, metric tons..... | 2,720 | 20,200 | (²) | (²) |
| Clay products | | 453,000 | | 460,000 |
| Lime, metric tons | | 92,026 | 11,050 | 102,700 |
| Sand and gravel, cu. m. | | 468,750 | 689,011 | 495,645 |
| Stone, cu. m..... | | 651,049 | 197,039 | 350,041 |
| Salt, metric tons..... | 19,147 | 574,511 | 19,500 | 575,000 |
| Mineral water, litres.... | 264,871 | 55,849 | 270,000 | 60,000 |
| Total | | ₱3,513,745 | | ₱3,944,581 |

¹Mineral products mined or manufactured, but not sold at the end of each year, are not included.

²The statistics for iron represent the quantity and value of iron castings, mostly plowshares.

³No silver is mined separately, but a small amount is alloyed with the gold.

⁴The figures for gold include about ₱200,000 estimated production by natives.

⁵No economic production. Several hundred tons was mined in the exploration of the Cebu coalfields.

Production of gold by districts in 1913.

| | |
|---|----------|
| Mancayan Suyoc, estimated Igorot production.... | ₱ 50,000 |
| Benguet | 83,281 |
| Ambos Camarines | 643,443 |
| Masbate (estimated) | 840,000 |
| Mindanao, estimated Filipino production | 60,000 |
| Nueva Ecija, estimated Filipino production..... | 30,000 |
| Pangasinan and lower Benguet, estimated Filipino production | 30,000 |

Total **₱1,736,724**

Production of gold by dredging, 1913.

| | |
|-------------------------------------|----------|
| Guamco Placer Company | ₱386,352 |
| Paracale Bucket Dredging, Ltd. | 101,232 |
| Maximelo Gold Dredging | 75,404 |
| Philippine Dredging Syndicate | 80,253 |

Total **₱643,241**

At present there are seven dredges operating in Ambos Camarines, and two more are being built. One dredge is operating in the Umaeri district, Tayabas province, and one dredge is to be built soon on the Mariquina river, near Manila. Three mills are operating in Masbate—the Colorado, Syndicate, and Keystone. In Benguet, the Camote is the only mill in operation, but two other small mills are being built, one by Captain Horr, and one by Clinton Hulberts. In lower Benguet, Lubang district, a small mill has recently been installed. The Cansuran Placer Mining Co. is installing sluicing plant at Cansuran, Surigao. Members of the Bureau of Science are: Alvin J. Cox, Warren D. Smith, Frank T. Eddingfield, Wallace E. Pratt, Paul R. Fanning, and Percy D. Kincaid.

Personal

S. R. GUGGENHEIM has gone to Europe.

COURTENAY DE KALB is in San Francisco.

JOHN W. MERCER was in San Francisco this week.

COREY C. BRAYTON has left San Francisco for Alaska.

J. B. TYRRELL is in British Columbia inspecting mining properties.

E. D. BARNETT, from San Luis Potosi, Mexico, was in San Francisco last week.

JOHN S. BUTLER has left Mexico and is spending a few weeks at his old home at Indianapolis, Indiana.

JOSEPH STRUTHIERS is now with the Johnson Electric Smelting, Inc., of New York, as second vice-president.

JOSEPH W. BOYLE, president and general manager for the Canadian Klondyke company, is in the Klondike.

F. C. MOORE, of Katanga, Central Africa, is visiting some of the large copper properties of the United States.

WILL C. HIGGINS, editor of *The Salt Lake Mining Review*, visited the mines of the Eureka, Juab county, district last week.

CHARLES ENDERLE, for many years engaged in the sale of Harrisburg engines in New York, is now with L. Copleston, Inc., 39 Cortlandt street, representing Ball Engines exclusively.

D. C. JACKLING and GALEN L. STONE were in Salt Lake City last week. After inspecting the Utah Copper mine at Bingham, they went to Butte to inspect the Butte & Superior mine and mill.

HENRY H. ARMSTEAD has been in Virginia making an inspection of the copper deposits of the Virgilina district. All of the properties operated by the Armstead United Companies, Inc., in Mexico are closed and in charge of Mexican watchmen. All of the American employees of this Company who have been on duty in Mexico landed at New Orleans by steamer from Puerto Mexico on May 15.

OFFICERS elected at the last annual meeting of the Chamber of Mines of Western Australia, at Kalgoorlie, are as follows: President, Richard Hamilton, of the Great Boulder Proprietary; vice-presidents, R. S. Black of the Kalgurli, W. A. Macleod of Bewick, Moreing & Co., R. B. Nicholson of the Ivanhoe, and J. W. Sutherland of the Golden Horse-Shoe; executive council, R. S. Black, Lloyd Bloxsome of the North Kalgurli, C. E. Crocker of the Kalgoorlie Electric Power & Lighting Corporation, P. Fitzgerald of the Oroya Links, R. Hamilton, W. A. Macleod, D. F. McAulay of the Associated, John Morgan, R. B. Nicholson, E. T. Randall, solicitor for the Chamber, G. M. Roberts of the Associated Northern, H. E. Vail of the Lake View & Star, and R. A. Varden of the Perseverance; sealholders, G. M. Roberts and R. A. Varden.

Obituary

J. T. LEMPRIERE, another well known Australian mining man, died as the result of an accident at Geebong, Victoria, on March 26.

JOHN DARLING, managing director for the Broken Hill Proprietary Co., and well known in Australian mining and grain circles, died in Melbourne on March 27.

J. E. STUBBS, president of the University of Nevada, died suddenly on May 27. Mr. Stubbs was born in Ashland, Ohio, in 1850, and during his life was noted as a scientific agriculturist and reformer.

CHARLES G. LATHROP, treasurer of Stanford University, died after an operation on May 23. He was the brother of the late Mrs. Leland Stanford, and when Stanford University was opened, he and his brother, Ariel Lathrop, assumed the business management.

MICHAEL O'ROURKE, pioneer mining man, died in Salt Lake City, May 12. He came West to Blackfoot, Montana, in 1869, and was identified with the Drumlummon company at Marysville, Montana, for many years. He later was superintendent successively of the Mammoth mill, Utah; Camp Bird mill at Ouray, Colorado; and Gold King mill at Gladstone, Colorado.

ALBERT ARENTS, after an illness of a year, died on May 13. He was born at Clausthal, Germany, March 14, 1840, and came to America in 1865, having been engaged to treat ores in Massachusetts. He came West in 1866, settling first in Nevada, where he invented and introduced many improvements in lead smelting, including the rectangular, large sized lead furnace, and the lead well or siphon cap. He later came to California and has lived in Alameda for the past 35 years.

Schools and Societies

STANFORD UNIVERSITY conferred degrees on 423 graduates on May 18.

THE INDIANA ACADEMY OF SCIENCE is holding its spring meeting at South Bend on May 28, 29, and 30.

THE COLORADO SCHOOL OF MINES held its fortieth commencement on May 22. An address was given by Dr. Rossiter W. Raymond.

COLUMBIA UNIVERSITY has issued its program for the fortnight May 25 to June 7. The 160th commencement will be on June 3.

THE AMERICAN INSTITUTE OF MINING ENGINEERS, Chicago section, has a membership of 58. An informal dinner and meeting was held on May 12.

THE FARADAY SOCIETY held its 72nd meeting on April 22 in London. The following papers were read: 'Recording Pyrometers,' by Charles R. Darling (this was discussed by a number of members); 'Diffusion and Membrane Potentials,' by E. B. R. Prideaux; 'The Acidic and Colloidal Properties of Aluminum Hydroxide,' by R. E. Slade and W. G. Polack; 'Negative Adsorption,' by A. M. Williams; and 'The Embrittlement of Iron by Caustic Soda,' by J. H. Andrew.

THE SCHOOL OF MINES OF WESTERN AUSTRALIA, at Kalgoorlie, has issued its syllabus for 1914, and annual report for 1913. The calendar for the current year runs from February 12 to December 5. The various departments are fully equipped with apparatus and machinery. There is also a large museum attached. Good scholarships are offered every year by the Government, Chamber of Mines, and others. There were from 140 to 179 students during 1913, who took up 40 different courses. In the examinations there were 40, 57, and 98 first, second, and third-class passes respectively. Save a few small charges, tuition is now free at this school, as it is at the new university at Perth.

THE U. S. Civil Service Commission, Washington, D. C., announces an open competitive examination for mining draftsmen, for men only, on June 17 and 18, 1914. From the register of eligibles resulting from this examination, certification will be made to fill a vacancy in this position in the Bureau of Mines, Pittsburgh, Pennsylvania, at an entrance salary of from \$1080 to \$1200 per year, and vacancies in positions requiring similar qualifications as they may occur, unless it is found to be to the interest of the service to fill any vacancy by reinstatement, transfer, or promotion. The subjects of examination are: (1) mining engineering; (2) drawing; and (3) training and experience.

THE COLORADO LOCAL SECTION of the American Institute of Mining Engineers, with the Colorado Scientific Society, the Colorado chapter of the American Mining Congress, and the Denver Chamber of Commerce, entertained Dr. Rossiter W. Raymond at a luncheon on May 21, at Denver.

The Metal Markets

LOCAL METAL PRICES

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, May 28.—The metal market is generally quiet. Copper is quiet but firm, lead is active, and spelter dull. Regular dividends have been declared by Chino, Nevada, Ray, and Utah copper companies. April copper yields are as follows: Utah Copper, 13,133,770; Calumet & Arizona, 5,450,000; Shattuck-Arizona, 1,386,594; Ohio, 692,400; Tennessee, 1,370,800; Cananea, 2,044,000; Arizona Copper, 3,570,000; East Butte, 1,178,000; Chino, 6,109,888; and Ray, 6,277,690 lb. Bar silver is steady in London at 26½d (52.5 cents).

SILVER

Below are given the average New York quotations in cents per ounce, of fine silver.

| June | 59.03 | | Dec. | 57.73 | |

In view of the certainty of a reduction of silver supplies in the near future, the fall of 0.5c. per oz. in London during the first week in May was rather unexpected; but the weakness throughout has been the paucity of buyers, according to Pixley and Abell. However, Bombay is for the moment fairly well stocked, and the bazaars, knowing that China is unlikely to buy much on this market at present, may be content to wait until their supplies are further reduced. Stocks in Bombay have fallen during the week to 1800 bars, but £570,000 is on the water. Although at the moment quiet, the undertone of the market is a strong one, and even a moderate demand would quickly affect rates. Supplies from Mexico have been practically cut off.

COPPER

Quotations on copper as published in this column represent average wholesale transactions on the New York market and refer to electrolytic copper. Lake copper commands normally 1-5 to 1-4c. per lb. more. Prices are in cents per pound.

Mineral exports from Broken Hill, New South Wales, in March were valued at £376,257, made up as follows: Silver-lead concentrate, 27,539 tons, value £264,563; zinc concentrate, 40,908 tons, value £104,812; silver-lead crude ore, 2754 tons, value £6225; and silver-lead slime, 869 tons, value £652. During the first quarter of 1914 the total was: Silver-lead concentrate, \$3,646 tons, value £781,812; zinc concentrate, 109,175 tons, value £278,032; silver-lead crude ore, 7207 tons, value £17,152; silver-lead slime, 2019 tons, value £1515; and zinc slime, 11 tons, value £17; making the total for the three months of £1,078,528 (\$5,175,000).

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

| Week ending | | May 14 | 39.00 |
|---------------|-------|--------------|-------|
| Apr. 30 | 39.00 | " 21 | 39.00 |
| May 7 | 39.00 | " 28 | 39.00 |

Monthly averages.

TIN

New York prices control in the American market for tin, since the metal is almost entirely imported. San Francisco quotations average about 5c. per lb. higher. Below are given average monthly New York quotations, in cents per pound:

Monthly averages.

| | 1913. | 1914. | | 1913. | 1914. |
|-----------|-------|-------|------------|-------|-------|
| Jan. | 50.45 | 37.85 | July | 40.70 | |
| Feb. | 49.07 | 39.76 | Aug. | 41.75 | |
| Mch. | 46.95 | 38.10 | Sept. | 42.45 | |
| Apr. | 49.00 | 36.10 | Oct. | 40.61 | |
| May | 49.10 | | Nov. | 39.77 | |
| June | 45.10 | | Dec. | 37.57 | |

The incessant liquidation by the chief bull interests, together with the continued eagerness of the Straits smelters to market their product, and some additional selling pressure by bears, produced acute weakness in the tin market early in May, according to Henry R. Merton & Co. of London. The rapid decline in the price at the beginning of the week alarmed some of the weaker holders to such an extent that they gave orders to clear out at any cost, with the result that prices dropped to the equivalent of £148 for cash. Thanks to the timely intervention of some of the leading operators, the market was, however, saved from demoralization, and steadier conditions began to prevail. These brought back some confidence to consumers who sent buying orders, which were followed by bear covering and ultimately led to a substantial improvement in prices as well as in sentiment. Prices rallied quickly to £154 to £155 in three months, and maintained the best part of the advance to the close, which is steady at £151 5s. cash and £153 5s. for three months. The considerable drop in prices, and the shake-out of many weak positions, has put the market on a healthier basis, but pending an improvement in general trade, or a falling off in production, there is evidence of an increasing surplus of metal during the summer months. The total transactions during the week amounted to about 2900 tons.

ORE TREATED from five of the principal gold mines at Kolar, India, in 1913 amounted to 808,507 tons, worth from \$7.52 to \$15.76, and costing from \$5.56 to \$6.88 per ton for all operations. Owing to a shortage of water for the Cauvery river power scheme, 90 miles transmission, during the current month, work at all the mines has been curtailed.

MICA PRODUCTION of the United States in 1913 was 1,700,677 lb. of rough trimmed and cut, worth \$353,517, and 5322 short tons of scrap, worth \$82,543, against 845,483 lb., \$282,823, and 3226 lb., \$49,073, respectively, in 1912. Imports were worth \$943,018. The outputs in Canada and India were valued at \$170,112 and about \$480,000, respectively.

COAL PRODUCTION of Wyoming in 1913 was 7,393,066 short tons, with a spot value of \$11,510,045, according to the U. S. Geological Survey. This production showed an increase of 24,942 short tons over 1912 in quantity, but a decrease of \$138,043 in value. There were 8331 men employed, with 34 fatalities.

THE WAIHI MINE, New Zealand, produced 14,136 tons of ore yielding bullion worth \$123,000 during the period March 14 to April 11. The output to date is \$50,400,000, and dividends paid, \$22,080,000.

COAL PRODUCTION of Washington in 1913 was 3,877,891 short tons worth \$9,243,137, increases of 516,959 tons and \$1,200,266 over 1912. There were 5794 coal miners employed, with 22 fatalities.

OIL PRODUCTION of California in April averaged 284,701 bbl. per day from 6002 producing wells. Stocks on April 30 were 49,625,570 barrels.

Company Reports

STANDARD SILVER-LEAD MINING COMPANY

Operations of this Company, which owns a mine and mill in British Columbia, resulted as follows in 1913:

| | |
|-------------------------------|-------------|
| Ore treated, tons | 13,959 |
| Silver produced, ounces | 1,081,849 |
| Lead, pounds | 17,988,805 |
| Revenue | \$1,069,247 |
| Net profits | 731,225 |
| Dividends | 650,000 |
| Surplus for year | 81,225 |
| Surplus at end of 1913..... | 246,348 |

TRONOH MINES, LIMITED

This Company operates a tin property in the Malay States, southeastern Asia. Results during the past financial year were as follows:

| | |
|--|----------|
| Black tin sold, tons..... | 2,187 |
| Revenue (tin ore realized £122 10s. per ton.)..... | £268,001 |
| Profit after allowing for depreciation | 59,806 |
| Balance from 1912 | 54,169 |
| Dividends | 60,000 |
| Balance to 1914 | 40,061 |

There was a considerable decrease compared with 1912, when the profit was £157,798. This was mainly due to the lower yield per cubic yard of tin drift.

BUTTE & SUPERIOR COPPER COMPANY, LIMITED

The work of this Montana company has attracted considerable attention during the past year or two, on account of the success of flotation as applied to its ores, its zinc production, and its litigation over the process with the Minerals Separation company. The reports of the president, N. Bruce MacKelvie, and D. C. Jackling, consulting engineer, contain the following information: Construction work is now practically completed. Spelter averaged 5.6c. per pound in 1913. The Company had a cash balance of \$225,294 at the close of the year, with shipments in transit to the smelter worth \$502,443. A dispute arose between this Company and the Elm Orlu Mining Co. concerning the Black Rock and Elm Orlu claims; but it was agreed that each Company could do what work it wished in the disputed area to settle the question of geological formation. A report is expected in a short time.

Development in the mine was confined to current mining operations, and principally to workings above the 1300-ft. level. No attempt was made to block out further reserves. A good deal of new ore was opened between 900 and 1300 ft. Ore reserves are estimated at 1,050,000 tons, compared with 1,200,000 tons in 1912, and average 21% zinc and 7 oz. silver per ton. There was 293,706 tons of ore mined at a cost of \$3.12 per ton. The mine is in excellent condition in every way, and above 1600 ft. several years' reserves are blocked out for the mill.

The mill treated 296,940 tons, at a cost of \$2.69 per ton, at an average recovery of 86.43%, this increasing from 58.79% to 80.15% during the year. Costs in December were \$2.05 per ton. The flotation plant yielded 104,174 tons of concentrate averaging 49.005% zinc and 24.19 oz. silver per ton; also 2269 tons of lead concentrate averaging 39.41% lead, 19.72% zinc, and 43.28 oz. silver per ton. The gross value of the product was \$3,526,661, and net income \$942,988. Out of this profit, \$761,414 was spent in acquiring further property and in mill improvements. Total costs were 4.45c. per pound of zinc contained in concentrate. An initial quarterly dividend of 75c. per share was declared during the current month, and will be paid on June 19.

TONOPAH MINING COMPANY OF NEVADA

This is one of the most important companies operating in Nevada, and the report covers the year ended February 28, 1914. The reports of the superintendent, W. H. Blackburn, the consulting engineer, J. E. Spurr, and the acting superintendent of the mill, F. F. Heydenfeldt, contain the following data: Development amounted to 17,924 ft., including sinking the Sand Grass shaft 448 ft. The Last Chance vein, developed from the Red Plume shaft, showed a considerable tonnage of high-grade ore. This vein has been opened from No. 4 level or capping to the No. 7 level. Its eastern boundary seems to be the West End rhyolite. This is to be proved by drifts and cross-cuts on the No. 5 and 7 levels. This vein had just been cut at the beginning of the year. The West End vein was opened during the year on No. 6 level between the buried fault and the property line. Where first found the metal content was high, but the average has been about \$15 per ton. Development work on No. 6 and 7 levels of the Sand Grass shaft exposed the contact of the West End rhyolite and Tonopah rhyolite breccia in several places, but no ore

GENERAL VIEW OF TONOPAH MINING CO.'S PROPERTY AT TONOPAH.

was opened. No. 10 level is now in the heavy quartz of the above contact. This body has a much more favorable appearance than the contact quartz encountered in the levels above. Considerably more development remains to be done from the Sand Grass shaft.

The estimated value of the total ore assets on March 1, 1914, were \$2,475,795. The estimated tonnage on March 1, 1914, was 172,761 tons, and includes assured, probable, and possible unbroken ore, ore on the dump, and ore stored at Millers, Nevada. The estimated value is \$14.33 per ton.

Total mining cost was \$3.278 per ton. Freight on ore to the mill was 74c. per ton.

The 100-stamp mill at Millers operated continuously 95.9% of the time, with an average duty of 4.65 tons of ore per stamp per 24 hours. Preparatory to some extensive changes, which are now being made to the mill, to provide for an allslime product for final cyanidation, the monthly tonnage to be milled each day was reduced from 500 to 400 tons on November 1, 1913. With these changes completed, the sand product, which does not yield to cyanidation readily, will be eliminated, and as a result a better extraction is expected to be obtained.

Milling costs, \$2.81, were 14c. higher than the previous year, which is accounted for by a lower tonnage milled during the last four months and a higher consumption of chemicals on account of the copper contained in the Red Plume ore. The consumption of cyanide during the year was 0.54 lb. more per ton than during the previous year. This increased consumption added 10c. per ton to milling costs. The combined extraction of both gold and silver for the year was 87.52%. Upon comparison with the previous year this shows metallurgically an increase of 1.65% gold and a decrease of 1.90% silver, or decrease in the total extraction of 1.82%, and in value the extraction was only 0.66% lower than during the previous year. The average gross value per ton of the ore milled was \$17.79, as compared with the previous year of

\$18.16 per ton. Including marketing mill products, total costs were \$7.41 per ton. Financial results were as follows:

| | |
|---|-------------|
| Ore treated, dry tons (ore contains 2.6% moisture) .. | 163,387 |
| Gold, ounces per ton | 0.247 |
| Silver, ounces per ton | 21.61 |
| Total revenue, including bullion, dividends, interest, loans, etc. | \$3,860,322 |
| Total expenditure, including costs, stock purchased, patents, loans, etc..... | 2,560,322 |
| Dividends paid | 1,300,000 |
| Surplus | 63,441 |
| Total net surplus | 3,975,353 |

The Company holds bonds in thirteen different industrial companies, and stock in six subsidiary companies. The latter include the Tonopah & Goldfield Railroad Co. and Tonopah Placers Co., which is operating three dredges at Breckenridge, Colorado. An option has been taken on a mining property in Nicaragua. Litigation over the Brown 'patent' process cost \$9345.08 during the year, resulting in a complete victory for the Tonopah company.

NATOMAS CONSOLIDATED OF CALIFORNIA

Reports of this well known dredge and land company are always read with interest, especially during the last year or two, when it has come in for a good deal of discussion. The report under review covers the year ended December 31, 1913. The profit and loss account shows the following:

| | |
|---|-------------|
| PROFIT | |
| Natoma dredges | \$ 632,254 |
| Feather River dredges | 360,112 |
| Water department | 17,949 |
| Rock-crushing department, Natoma and Oroville.... | 73,945 |
| Discounts, interest on investments | 7,970 |
| Interest on Reclamation District 1000 warrants and bonds | 72,212 |
| Total profit | \$1,164,442 |
| LOSS | |
| Loss on crop season 1913 | \$ 12,556 |
| Interest on bonds | 980,534 |
| Miscellaneous | 63,512 |
| Total | \$1,056,602 |
| Net profit before writing off depreciation or bond discount | \$ 107,840 |
| Balance at January 1, 1913 | 1,300,520 |
| Profit for 1913 as above | 107,840 |
| Total | \$1,408,361 |
| Deduct loss on No. 7 dredge..... | 129,394 |
| Balance | \$1,278,967 |

The report of the consulting engineer, Charles M. Rolker, contains the following information, among a number of explanations and discussion of past work: The dredging time of the whole fleet was 82.3% in 1913, similar to 1912 and 1911. Work in the Natoma division was disappointing, as the yardage handled was 2,576,015 cu. yd. below the estimated amount. In the Feather River division, 69,163 cu. yd. more was dredged than had been estimated. At Natoma, No. 1 boat was digging in hard clay and gravel, and shallow classes of ground at different times, and worked 78.58% of the possible time. No. 2 and 3 operated satisfactorily. No. 4 encountered large quantities of clay and gravel, 6 to 10 ft. of hardpan overburden, and some bedrock, and worked 79.8% of the time against 84.87% in 1912. No. 5 sank in June and started again in November. This was due to a sudden lurch of the boat when digging very hard formation, which lurch shook the stack ladder and caused it to pull loose one of the guys that was attached to an eyebolt below water-line, allowing water

to enter through a hole made in the planking. Repairs cost \$82,180. No. 6 dredge had to dig a good deal of cement and clay. No. 7 sank in May 1912, and was reconstructed and started again in May 1913. The new boats, No. 8 and 9, worked 80.61 and 84.03% of the time. Both were troubled with clay sticking to the buckets, which could not discharge the sticky material. No. 10 encountered irregular surface, big boulders which stuck in the buckets, had to cross a road, and suffered from loss of water in the pond on account of configuration of the ground. Repairs cost \$50,000, which is high for a boat 15 months old.

No. 8, 9, and 10 dredges have 15-cu. ft. buckets, and No. 5 and 6, 9-cu. ft., and the reduction of costs with the larger buckets against the smaller should theoretically be 12% in every department save power. This was not the case. The comparative cost per yard, excluding power and reconstructing cost, was as follows: No. 8, 5.05c.; No. 9, 5.39c.; No. 10, 4.09c.; No. 5, 3.67c.; and No. 6, 4.08c. per cubic yard. These dug 273.1, 322.9, 359.7, 250.7, and 229.1 cu. yd. per hour, respectively. The following table shows the work of the dredges in 1913:

| | Oroville. | Natoma. | Total. |
|-----------------------------|-----------|-------------|-------------|
| Dredges working | 3 | 10 | 13 |
| Gravel dredged, cu. yd.... | 5,499,163 | 18,907,985 | 24,407,148 |
| Recovery, cents per yard... | 11.26 | 8.88 | 9.42 |
| Total gold | \$619,102 | \$1,680,158 | \$2,299,261 |
| Cost, cents per yard..... | 4.71 | 5.54 | 5.35 |
| Profit, cents per yard..... | 6.55 | 3.34 | 4.07 |
| Total profit | \$360,112 | \$632,254 | \$992,367 |

The net dredging profit for 1914 is estimated at \$1,300,000. The rock-crushing plants produced 425,143 tons of finished

ROCK-CRUSHING PLANT AT OROVILLE.

rock and 346,492 tons of screenings, yielding a gross return of \$259,129. Crushed rock on hand amounted to 89,501 tons at the end of 1913.

The report deals with reclamation lands leased, amounting to 20,349 acres, and 9636 acres of irrigation lands leased. In the Bear River garden tract, 500 acres was leased at \$5 for general agriculture, and 305 acres for beans at \$6 per acre. The Company proposes to cultivate 3100 acres on its own account.

In district No. 1000 the engineering department estimates the work remaining to be done to cost \$808,186, exclusive of irrigation; district No. 1001, \$926,730; and work on irrigation lands, \$1,703,185. This includes the Company planting 1000 acres with rice. The total land holdings of the Company, including the dredging area, is 96,213 acres. The estimated income for 1914, exclusive of discounts and interest, is \$1,406,325. The capital stock of this Company amounts to \$16,068,800, par value \$100 each; and bond issues for all purposes, \$17,375,000.

Assets are valued at \$43,213,899, the dredging properties being worth \$14,433,532. Since January 1, 1909, and up to December 31, 1913, the dredges have recovered gold worth \$9,716,479, at a profit of \$5,115,829.

Book Reviews

COMPRESSED AIR. By Theodore Simons. McGraw-Hill Book Co., New York. P. 160. Index. For sale by the *Mining and Scientific Press*, San Francisco. Price \$1.50.

This work has been prepared primarily for the use of students who desire to obtain an insight into the natural laws and physical principles underlying the production, transmission, and use of compressed air. Examples for practice are interspersed among the reading matter for the use of the student. Practically all of the modern types of air-compressors are illustrated and the characteristics of each discussed. An appendix is also given of tabulated data for the assistance of the reader in making quick calculations.

COMPRESSED AIR PRACTICE. By Frank Richards. McGraw-Hill Book Co., New York. P. 319. Index. For sale by the *Mining and Scientific Press*, San Francisco. Price \$3.

In the author's preface Mr. Richards draws attention to the fact that the cost of power and fuel for the compressed air now used is not more than one-third as great per quantity unit as it was twenty years ago. This statement in itself is significant of the wonderful changes that have been made during the last two decades in the design of compressed air apparatus. Mr. Richards' work, while not voluminous, deals in general with all of the more prominent applications of compressed air, as well as giving a brief discussion of the elementary principles and fundamentals involved. The matter of the design of the compressors themselves is not taken up and, as Mr. Richards says, "Catalogue literature and auctioneer talk have their places, but not here." As a book of reference to the busy man this work is of exceptional value and blazes the trail for those who desire to undertake a detailed investigation of any specific application.

STEAM TURBINES. By James Ambrose Moyer. John Wiley & Sons, New York. P. 368. Index. For sale by the *Mining and Scientific Press*, San Francisco. Price \$3.50.

The author draws attention to the remarkable progress that has been achieved in steam-turbine design during the last few years and brings out the fact that the steam turbine is the oldest and at the same time the most modern steam motor. This is the second edition of Mr. Moyer's work, the first having been published in 1908. Since the first edition was published the evolutionary tendency in the adoption of types of steam turbine has been toward a concentration upon practically four instead of the many designs in vogue at the time the first edition was published. A tendency toward the installation of increasingly large sizes is also pointed out. An instance is cited of the largest turbo-generator now installed rated at 35,000 kw. in comparison with a maximum size of 14,000 kw. only three years ago. This concentration of power in large units shows an extension of the principle of consolidation that has made itself manifest in many other directions and has resulted in a great reduction in the cost of power of this kind per kilowatt installed. New chapters have been added on bleeder or extraction turbines and on mixed pressure turbines. The chapters on heat theory, steam flow, nozzle, blade, and reaction turbine design have been rewritten with the addition throughout the text of many illustrative examples. The appendix has been enlarged by the addition of many practical exercises and problems illustrating important parts, thus increasing the usefulness of the book as a classroom text. A new entropy total heat chart has been calculated and engraved, which embodies the most recent and reliable data on the properties of super-heated and saturated steam.

FUELS USED IN TEXAS. By William B. Phillips and S. H. Worrell. Bulletin 307. P. 287. Ill., index. University of Texas, Austin, 1913. There is plenty of cheap fuel in this state. The total area of coal and lignite is 58,000 square miles. Petroleum production of the state since 1889 totals 168,721,719 bbl., worth \$82,754,292.

COAL MINING PRACTICE IN DISTRICT VIII (Danville). By S. O. Andros. Field work by R. Y. Williams and S. O. Andros. Bulletin 2. Coal-mining investigations, cooperative agreement of Illinois Geological Survey, University of Illinois, and U. S. Bureau of Mines. P. 47, Ill., map. Urbana, 1914. A useful compilation for coal miners.

PENN STATE MINING QUARTERLY. P. 46. Ill. State College, Pennsylvania, April 1914. Contains besides school notes the following papers: 'Application of Central Station Power to Coal-mining Work,' by Thomas R. Hay; 'Excursions of the International Geological Congress,' by E. S. Moore; and 'Methods of Working, Ventilation, and Transportation in Bituminous Coal Mining,' by Thomas A. Mather.

EDUCATION OF MINE EMPLOYEES. By H. H. Stoek. Bulletin 1. Illinois Miners' and Mechanics' Institutes. P. 136. Urbana, Illinois, 1914. Welfare work by mining and industrial corporations among its employees is attracting considerable attention. With better surroundings and conditions of work, better efficiency is sure to result. This publication covers the work done in foreign countries as well.

CONSERVATION OF COAL IN CANADA. By W. J. Dick. P. 212. Ill., maps, plans, index. Commission of Conservation, Toronto, 1914. Practically all of the most populous portion of Canada lying between Montreal, Quebec, and Moose Jaw, Saskatchewan, relies solely on the United States for its supply of anthracite coal. Further, there are indications that the United States may, in the comparatively near future, prohibit the export of anthracite, and, as the only anthracite deposits so far discovered in Canada are confined to the area near Banff, Alberta, it is of great importance that suitable substitutes be found as soon as possible. Such a situation makes it clear that Canada should carefully husband her coal resources and, so far as possible, check all wasteful methods of mining and handling coal. With this end in view, the recommendations in this report are of great value.

Industrial Progress

Oil-Driven Air-Compressors

The increased use of low-grade oil fuel for power purposes has led to the design, by the Ingersoll-Rand Co., of the oil-engine-driven air-compressor. This is of the direct-connected straight-line type and somewhat resembles in this respect, as well as in the design of the air end, the Company's standard line of small compressors. The main frame is designed for a splash system of lubrication, is of the wholly enclosed type, and provided with removable covers.

OIL-DRIVEN AIR-COMPRESSOR.

The feature of greatest interest in this machine is the design of the driving end. This, as can be seen from the illustration, consists of a single oil-engine cylinder set behind the air cylinder, and directly connected, by means of an extended piston-rod, to the air piston. It follows in general design a type known as the 'hot bulb' engine, which combines a high thermal efficiency with simplicity of construction. The power cylinder is of the single-acting two-cycle type. It is water-jacketed, provided with an efficient system of lubrication, and of sturdy design. It is fitted with a torch for heating the ignition bulb preliminary to starting. After the compressor is under way this torch is dispensed with.

The fuel is automatically injected into the combustion chamber by means of a small pump, on the side of the frame, operated by the main shaft. It enters in the form of a finely atomized spray and is immediately ignited by the hot bulb, dispensing entirely with the electric spark and batteries. The stroke of the fuel pump is regulated by a centrifugal governor in the fly-wheel, thus regulating the amount of fuel injected into the cylinder in proportion to the load. This is supplemented by a regulating device on the intake to the air cylinder of standard design.

The operation of this machine is accompanied, it is claimed, by none of the losses common to the average two-cycle gasoline engine, in which part of the incoming charge follows the exhaust gases through the outlet ports and is wasted. This is due to the fact that the fuel is not vaporized by an outside agency and introduced with the air used for scavenging, but is injected directly into the cylinder at the end of the compression stroke, as already mentioned.

This means that pure air is used during the scavenging period of the stroke, consequently the inlet and outlet ports can be so arranged that more thorough scavenging is afforded without any loss of fuel. The absence of carburetor, with its needle valves, springs, and adjustments which have to be changed to suit atmospheric conditions, is one of the features of the engine.

A small quantity of the water from the cylinder jacket is introduced into the combustion space. The water is said to regulate the temperature in the cylinder, thereby preventing an undue rise in temperature of the piston and causing dissociation of the fuel. It is claimed to reduce the maximum pressure in the cylinder, at the same time slightly increasing the mean effective pressure, making a smooth-running and highly economical machine. The amount of water injected is regulated according to the load on the compressor.

The whole machine is compact and self-contained. It is at present made in but one size with an actual capacity, when running at 325 r.p.m., of 66 cu. ft. of free air at 100 lb. pressure and 73 cu. ft. at 80 lb. pressure. The fuel consumption at this speed, and under average operating conditions, is about 2.2 gallons of kerosene per hour. It is adapted to run on either kerosene, fuel oil, or distillate. Its weight complete is 3000 lb., and occupies a floor space of 8 ft. 10 in. by 2 ft. 5 inches.

Cold water paint manufactured by H. W. JOHNS-MANVILLE Co., of New York, is claimed to render mine workings less dangerous, and is also useful as a fire retardant and medium for improving sanitary conditions. This paint can be utilized in the underground station; increasing the light in and about the pumps is not only a help to the men, but it lessens the possibility of accident. It can be used for a large variety of purposes about the mine or mill. J-M cold water paint comes in dry powder form, is easily mixed, and possesses unusual whiteness. It is durable and costs but little more than ordinary lime wash. This paint is highly fire retardant, and a heavy coating on timbers is an aid in preventing fire. As it is also sanitary, its use in the various buildings connected with the mine is desirable. The manufacturers of this paint have prepared a booklet on this product, a copy of which will be forwarded to anyone interested.

The first exhibit to be installed at the Panama-Pacific International Exposition will be an immense 500-hp. Diesel oil-burning engine, and will be exhibited by the BUSCH-SULZER DIESEL ENGINE Co. of St. Louis. The installation will cost \$70,000 and will require six months to complete. The Company manufacturing the Diesel engine commenced the preparation of foundations for the mammoth exhibit on April 1. That the first exhibit to be installed should be the Diesel engine and one of great interest to California, as it will open a large field for the marketing of crude oil, was considered especially appropriate.

The B. F. GOODRICH Co., at Akron, Ohio, has devised an important improvement in dredging sleeves. A fabric of special design has been used in the solution of the expansion problem in dredging sleeves, and the new Goodrich sleeve, as perfected, reduces expansion to an absolute minimum. The durability of dredging sleeves, no matter how good their other features, can be seriously impaired by excessive expansion. The improvement will apply to general engineering where the dredging sleeve is an important item.

The DEISTER CONCENTRATOR Co. has filed suit against the Deister Machine Co., in the United States District Court for the District of Indiana, for infringement of patent issued to Gustave Overstrom and purchased by the Deister Concentrator Co. The complaint cites that the Deister Machine Co. is using a certain feature on its concentrating tables called a 'plateau' and is also endeavoring to place this feature on tables of other makes. It is claimed that the so-called 'plateau' is an infringement on the Overstrom patent.

The ABENDROTH & ROOT MANUFACTURING Co., makers of the Root spiral riveted pipe, with works at Newburgh, New York, has its general sales office in the Hamburg-American building, 45 Broadway, New York City.

EDITORIAL

ALBERTA has been the scene of an oil and gas excitement for some months, and this will be accentuated by the bringing in of a well last week which is reported to flow 2,000,000 cubic feet of gas and an important amount of high-grade oil. Near Calgary, where this well is situated, there is a wide stretch of territory that seemingly warrants exploration, and it is to be hoped that further drilling may give even better basis for the development now under way.

LIMITATION of diamond production is to be the subject of a conference by the leading producers of South Africa this month. While the De Beers Consolidated Mines and the Premier (Transvaal) Diamond Mining Company, have long been market rivals, the competition has produced no visible results in reduction in price. Last year's South African production of 5,163,545 carats, valued at £11,389,897, is evidence of the annual tribute exacted by vanity and the magnitude of the industry which it supports.

INTEREST in new processes is always keen, and we are glad to present an authoritative account of Murex by Mr. James M. Hyde, who recently investigated its operation in Germany and elsewhere. In our London letter, and various short articles, our readers have been informed of the development of this new aid to metallurgy, but this is, we believe, the first authoritative account presented in America of a Murex plant in actual operation. It is hoped that the process will find application in a number of directions where peculiar ores call for peculiar means.

STUDENTS of ore deposition are receiving new and welcome aid from the reflecting microscope. As yet the technology is simple, much as was that of the now ordinary petrographic microscope in the days of Zirkel's first work. The French mineralogists, working out the optical properties of minerals, gave Rosenbusch a basis for systematic petrography and doubtless in time a complex technic for the reflecting microscope will develop. In the meantime we take pleasure in presenting the article by Mr. James C. Ray, who shows by careful account of a specific set of specimens just what it is now possible to learn. Mr. Ray is at Stanford University, as always an active centre of research.

METAL MARKETS for May have been quiet, and a revival of business depends largely upon the pending freight rate decision, according to reports from New York. Stocks of railroad supplies are low and every effort is being made to avoid buying. The prices of all metals weakened in May and general trend has been downward. On another page of this issue will be found the monthly detailed analysis of the metal market in New York by our special reporter of the metal markets.

WORKMAN'S COMPENSATION is being considered by the state of Idaho and in a report recently submitted by the commission which was appointed about a year ago to investigate this subject, an outline of the proposed law is presented. It includes a number of features of constructive legislation based upon the experience of other states and foreign governments, together with a few radical departures. The administration of this proposed department will be in the hands of a board including the Commissioner of Labor and Immigration, the State Insurance Commissioner, and a third appointed by the Governor. In this manner a satisfactory administration is provided with but little added expense for operation. In order to eliminate disputes, beneficiaries are defined as including only the wife and children in the first instance, but in the absence of a family, the father and mother receive a less rate of compensation, and minor dependents, as brothers or sisters, still further reduced amounts. No compensation is allowed during the first two weeks. The compensation differs with the earning capacity of the workman, not, however, exceeding \$10 per week, nor is it to continue more than 300 weeks for temporary disability. In case of total disability the law provides for payment 400 weeks at the scheduled rate, after which payments of \$5 per week during the life of the workman. Specific schedules are provided for dismemberment, paralysis, loss of sight, and other injuries which are all properly related to a maximum of \$2000. Three plans of compensation are proposed. The first permits financially solvent employers, upon making a deposit of 3 per cent of their annual payroll, to settle and pay direct, but under supervision of the board. Another plan provides that the employer may insure his risk, where he does not care to exercise other options under the bill or his financial standing does not meet the approval of the board. The third plan is modeled after the law of the state of Washington, whereby occupations are divided into classes according to the hazard of the occupation and a varying rate is assessed each class. The bill shows that much study has been given to it and every effort has been made to profit by the experience of other states. Such careful and deliberate work by an executive body is to be commended and will undoubtedly redound to the benefit of both employer and employee. Workmen's compensation laws are, we believe, more than a fad. Some of them are crude, but the principle is sound.

Colorado Smelters

The effort which is being made by the mining interests in the state of Colorado to resuscitate metal mining and give it a new lease on life has recently taken the form of proposed legislation for the establishment by the state of three smelters. When the federal government proposed to withdraw radium deposits from entry, development of this new industry was looked to by many to set prospectors and miners at work again, but with the failure of the radium bill to become a law, interest has seemingly waned and the smelting situation has come in for renewed discussion resulting in the proposed constitutional amendment.

The petition as prepared provides for a \$4,000,000 bond issue which will be used to build smelters and treat ores under state supervision. The plan, as reported, is to construct and operate smelters at Denver, Pueblo, and Durango. It is planned to equip the Denver plant with machinery for the reduction of ores containing radium and other rare and precious metals. This plant will cost \$2,000,000 according to specifications. The plants at Pueblo and Durango will cost \$1,000,000 each. The proposed bonds for financing these smelters will be known as 'state smelting bonds' and will bear three and a half per cent interest payable semi-annually. The bonds are redeemable at any time after five years and must be paid off within 50 years. The object of the proposed enactment is, of course, to foster the mining industry. Whether this putting the state into industry is the correct solution of the difficulty may well be doubted. It is not smelters but mines that Colorado needs, and you do not grow crops by buying threshing machines. To our way of thinking, there is a radical difference between proposal to enter smelting wholesale for the sake practically of furnishing work and the more modest proposal that the federal government should reduce radium ores, primarily to supply its own hospitals. Colorado did not take kindly to the latter suggestion, and we fail to see any good reason for supporting the more radical substitute now proposed.

It would seem that if there were any urgent demand for additional smelter capacity in Colorado, private capital would have found it out. In point of fact, there is excess capacity now. While an additional bonded indebtedness of \$4,000,000 is not a great amount for Colorado to assume, we question whether it might not be better employed in another field of the industry. The discovery and development of new ore-bodies and the treatment of low-grade and complex ores is the subject of importance to the Colorado miners and if the work of the State Geological Survey and the research work of the Bureau of Mines could be augmented, a greater return on the proposed investment might be possible. The value of the mineral production of Colorado for the past 20 years shows an increase from \$28,012,524 in 1894 to \$50,314,019 in 1900,

which is the largest production recorded. Since 1900 the general trend of the industry in the state has been downward with an occasional year which showed a slight increase until in 1911 the value of the production, as reported by the State Bureau of Mines, was only \$32,731,866. In 1912 the production increased to \$37,033,280 but whether this would indicate a general upward movement in the industry or is only a temporary fluctuation in production remains to be proved. A comparison of the production statistics for 1900 and 1912 show that a general decline has been experienced in most of the counties of the state, a few remaining stationary or showing a slight increase, these latter, however, are in the decided minority. The problem which Colorado miners face appears to be one of exploration for new and research into the economic treatment of known ores rather than increasing the present smelting capacity.

The Outlook

Everyone is necessarily interested in the prospects for an early revival of business activity. That the past year has been a dull one for general business is true without any possibility of question. It is equally generally hoped that before the end of this year a marked revival of business activity will ensue. Just when it may be expected is the crucial question. For this reason the views of men prominent in the world of affairs are of great general interest, since presumably they have available sources of information which are not within the reach of the ordinary man. The most optimistic of recent statements is that of Mr. E. P. Ripley, president of the Atchison, Topeka & Santa Fe Railroad. Mr. Ripley sees in the prospects of unusually large crops for this season the basis of a general injection of snap into business. Crops are not only among the largest direct items of business, but also are the source of a great deal of indirect business. Their transportation and manufacture from the raw state into food products and their retailing affords employment to a large proportion of our population. It follows directly, therefore, that large crops mean good business, and there is much justification for the belief that in the apparently assured unusually large crops for this year lies the germ of a marked increase of the volume of business. Another optimistic statement recently made is that by Mr. James A. Farrell, the president of the United States Steel Corporation, who has just returned from Europe and who has expressed himself as believing that business generally is emerging from an unsatisfactory condition into a satisfactory state of commercial confidence. Both in England and Germany strong efforts are being made to increase trade, and their lead is at last being followed in this country, the National Foreign Trade Convention held at Washington last week being a commendable, useful attempt to stimulate the export business of the United States. Mr. E. H. Gary, chairman of the United States Steel Corporation, in a recent address, while admit-

ting the present depressed state of business, is also confident that a marked revival will soon come and takes the cheerful view that the considerable period which has passed without its arrival means that we are that much nearer to it.

That not all business is depressed is shown by the report of the Westinghouse Electric & Manufacturing Company, which for the year ended March 31, 1914, declared a dividend of 10.7 per cent on its common stock, as compared with 8.2 per cent for the preceding year. Machinery such as this Company produces may be looked upon as, in a way, the semi-finished products of general business, since it goes into use by the general public and the large corporations. So favorable a report as this by an organization of such widespread activities indicates that business is fundamentally sound and that it is merely a question of time when the general condition will be more optimistic than at present. In the special field of mining, the unsettled state of Mexico has undoubtedly contributed greatly to cause a depression which otherwise would in all probability have scarcely been noticeable. Here again there is room for optimism, however, for there is ground for belief that the present condition in Mexico may possibly be satisfactorily remedied at a not too distant date. It is unquestionable that when a peaceful and stable government is restored to Mexico, a decided boom in mining in that country, with reflex action throughout the mining world, will follow.

It is gratifying to note that the administration is taking steps toward the development of the foreign markets for American products and increasing the merchant marine. It was announced at the Foreign Trade Convention in Washington that Mr. Wilson authorized the statement that he would devote personal attention to procuring legislation for upbuilding the American merchant marine. This is an important but difficult task, and as to means, there is no agreement as yet. Greater foreign markets will stabilize the home industries, as pointed out by Mr. Farrell, and this is of vital interest to the American people. The importance of the matter is shown by the immensity of the present foreign trade of the country, which amounts to \$2,500,000,000 annually, of which about eighty per cent represents labor. It has been pointed out that it is not only essential that the American people should make an effort to extend their foreign markets to enhance their prestige and wealth, but it is also becoming a necessity in order that the domestic consumption of the country, now recurrently insufficient to absorb the whole output of our mills and workshops, be stabilized. The subject is most important to American industry, and in that we have been lagging in this respect in the past, the concerted effort which is now being made by the producers and backed by government aid should be productive of results. Sentiment is generally optimistic regarding the success of the proposed extension of the lines of trade, and we are hopeful that the increase may come rapidly.

The Reflecting Microscope in Mining Geology and Metallurgy

By JAMES C. RAY

In 1873 Ferdinand Zirkel published his first paper¹ giving the results of a study of rocks in thin sections with the polarizing microscope. Prior to this all attempts toward the systematic classification of rocks were based on megascopic examination and geologic relations as observed in the field. By these earlier methods a true understanding of the relations of rocks to each other, as now grouped in petrographic provinces, as well as the relation of the constituent minerals and their alteration products, was not known; the resulting classifications being faulty as well as inconsistent.

At this early date petrography was considered a pure science only and its application to the study of ore deposits were not appreciated. A brief review of the development of microscopic petrography from the introduction of the polarizing microscope and its general acceptance in the iron and steel industry to its later application in the field of economic geology may be timely.

Microscopic Study of Rocks

The appearance of Zirkel's first paper gave great impetus to the microscopic study of rocks and the rapidity with which this science was developed is most striking. With the identification and understanding of rock alterations came the discovery that often these alterations are connected genetically with ore deposits. As mineral synthesis and physical chemistry developed, the microscope came into greater demand for a study of the wall or country rocks in connection with the examination of ore deposits.

The majority of ore deposits occurring in veins fall into the class developed by hydrothermal processes (ascending hot solutions). Propylitization, sericitization, greisenization teach us much regarding the chemistry of ascending ore forming solutions. Many of the mineral alterations caused by cold descending solutions are distinct from those just mentioned and if a definite idea of the type of alteration accomplished by the ore depositing solutions be discriminated, the type of solution which produced any given ore deposit may be stated with some certainty. This and many other phenomena help to a clearer understanding of the genesis of ore deposits and can be recognized and worked out only by the use of the microscope. These points are of such vital value that today the mining geologist gives considerable time to a study of the associated rocks in connection with his examination of ore deposits.

In the study of thin sections of rock with the polarizing microscope, however, the source of light is from

¹Ferdinand Zirkel, 'Die Mikroskopische Beschaffenheit die Mineralien und Gesteine.' Prior to the above date Sorby had done considerable microscopic work on sedimentary rocks but I am unaware that he attempted systematic classification.

below and does not illumine the surfaces of the opaque minerals. For this reason until recently little has been known of the intimate relations existing in sulphide (or other opaque mineral) mixtures, and the manner of their enrichment. These are of much importance in the true determination of the value of a deposit, as when these relations are known, the periods of mineralization and enrichment can be clearly followed, as will be later demonstrated.

In 1863 Sorby began the study of meteorites² and artificial irons³, and some years later this work was carried on by other investigators; but the economic application of the work was not generally recognized. It is only within the last 15 years or so that the importance of metallography to the steel manufacturer has been recognized and the gradual advance of this branch of microscopy has been resisted at every step by the old guard of foundrymen.

The steel chemist had a hard fight to gain recognition but after his final acceptance it was thought that little more remained to be learned regarding the internal properties of steel. It soon became evident, however, that the ultimate analysis of a steel left much in doubt regarding the structure which controlled to a large degree the physical properties of this material. Howe⁴ brought out clearly in 1890 that even the proximate analysis was not the final word in an understanding of the properties of steel, as the structure was still in doubt. Finally, with the introduction of the reflecting microscope this also was made possible. The recognition of this fact has brought about the establishment of metallographic laboratories in connection with all of our large steel plants. Special courses are also given in most of the larger universities, dealing with this phase of the metallurgy of steel.

Examination of Opaque Substances

In 1906 William Campbell published two papers dealing with the application of the reflecting microscope to opaque substances other than steel. The first of these papers⁵ described methods of grinding, polishing, development of structure, mounting, etc., of specimens to be studied, also the explanation and use of the reflecting microscope. The second paper⁶ was accompanied by microphotographs and gave a detailed description of the study (with the reflecting microscope) of the nickel arsenides and silver deposits of Temiskaming, Canada. These two papers directed anew the atten-

⁵Economic Geology, Vol. 1, p. 751.

⁶Loc. Cit., p. 767.

tion of economic geologists to the possibilities of this means of studying the occurrence of opaque ore minerals and gave new impetus to the development of this hitherto neglected branch of economic geology.

In the preparation of polished sections, each investigator soon develops his own method of procedure. The one given below I have found to give excellent results from the point of speed and production of a polished surface, free from scratches.

Preparation of Specimens

The equipment should consist of the following: two iron discs such as are used for the preparation of thin rock slides, one heavy wooden or iron disc covered with lapidaries cloth, and one iron disc covered with a good grade of broadcloth. These discs revolve horizontally at about 250 revolutions per minute. The equipment should also include a diamond or disc saw. The abrasives are, No. 50, No. 100, and No. 200 carborundum powder, tripoli powder, and gold rouge. The discs must be carefully separated by partitions high enough to prevent the powder from flying from one disc to another.

The specimens to be polished should be about one inch square and one-half inch thick and can be broken from the larger samples or accurately sawed if it is desired to examine some particular part of the specimen. The trimmed specimens are roughly surfaced on the first disc with No. 50 carborundum powder, next they are more carefully ground on the second disc with No. 100 carborundum. When all the specimens on hand to be polished have been put through the second stage of preparation the disc should be carefully cleaned and a false lining set in the compartment. The specimens are now carefully ground down with the No. 200 carborundum to eliminate all scratches visible to the naked eye. With some minerals it is necessary to finish the grinding with a few turns on a glass plate.

Next make up a thin paste with water and tripoli powder and proceed to the first polishing on the lapidaries cloth. Great care must be exercised to keep the cloth free from hard particles as any scratches contracted at this stage can not be eliminated without re-grinding. The final brilliant polish is produced on the fourth disc covered with broadcloth. A thick paste of the gold rouge is sparingly applied to the broadcloth and the specimen lightly held on the wheel for only a few turns.

Running water should be handy and the specimens washed frequently during the entire process. The hands of the operator should be carefully scrubbed after each part of the process has been completed that no particles of powder may be carried to the disc using a finer grade of powder. With the above method the average time per polished section is ten to fifteen minutes.

If a table microscope is used the specimens are most conveniently mounted temporarily as examined. The most effective mount is the cylindrical metallic cup, $\frac{1}{2}$ to 1 inch deep and $1\frac{1}{2}$ inches in diameter. To

mount, the specimen is placed face downward on a smooth piece of glass covered with a thin sheet of paper. A plastic wax is put in the cup which is inverted and placed over the specimen and pressed down until the sides of the cup are firmly in contact with the glass plate. The polished section is thus held parallel to the microscope stage when the cup is placed on it. Most of the large metallographic microscopes are arranged so that the specimen is placed directly on the stage face down and mounting is unnecessary.

In the study of thin rock sections the source of light is from below, the light rays being transmitted upward through a condensing lense and are polarized before passing through the transparent rock section.

In the study of opaque minerals, metallic alloys, etc. the light must be thrown down upon the polished surface. This is accomplished in two ways: by a small right angle prism set in the objective and by a thin glass plate set either in the objective or below it at an angle of 45° with the optical axis of the microscope. Light, either natural or artificial, is thrown upon either of these reflectors and is directed downward to the polished surface of the specimen. If the polished surface is exactly normal to the optical axis of the microscope the light rays are again reflected vertically upward through the lenses of the microscope and the image in the field is thrown against the eye.

Identification of Opaque Minerals

Opaque minerals are identified in five ways:

1. Natural color of the mineral.
2. Relief in polished section (hardness).
3. Structure, natural or artificially developed by reagents, acids, etc.
4. Tarnish films, developed artificially by reagents.
5. Microchemical tests. (A drop of reagent is applied to the polished surface in the field and its action on the minerals observed through the microscope.)

When a series of specimens is to be examined, the preliminary determination of the constituent minerals by the last three means of determination enables the detailed study of mode of occurrence, association, and replacement to proceed with little delay. The first two methods (color and relief) and natural structure are used to determine the constituent minerals. The systematic study of opaque minerals, by the reflecting microscope, is at present so young that no tables giving complete and reliable tests exist in published form.

Max Leo¹ has published a paper giving some very satisfactory tests for the yellow sulphides. In many instances, however, his tests are inapplicable to minerals occurring in microscopically small particles. What promises to be a complete and satisfactory table of tests is looked for in the near future from Joseph Murdoch who has devoted much time to this subject in connection with the work of L. C. Graton².

Since the appearance of the paper by Campbell and

¹Max Leo, *Die Anlauffarben*, Dresden, 1911.

²See statement by Graton, *Trans. Amer. Inst. Min. Eng.*, May, 1913, p. 805.

Knight on the Temiskaming district (1906) most of the investigations have been made on the copper sulphides and titaniferous iron ores. The most important paper on the former by Graton and Murdoch,⁹ appeared last year (1913) and is of great interest to the mining geologist. Titaniferous iron ores have been exhaustively studied by Joseph T. Singewald¹⁰. His work is of vital interest to the iron metallurgist as it shows titanium to occur as the mineral ilmenite and the structure of the ore has much to do with the successful magnetic separation of the useful iron minerals.

The present development of the study of opaque ore minerals by the reflecting microscope has accomplished the following results: (1) the identification of most of the common opaque minerals in polished sections; (2) the identification of mineralogical associations and physical structure of ores; (3) furnishing of means for following the processes of enrichment, replacement, and alteration of ore minerals; (4) identification and separation of different periods of mineralization in the same orebody; (5) identification of reopening or movements in orebodies; (6) the accurate genetic grouping of veins in any given district.

Micrographs

The following microphotographs of polished sections will serve to illustrate what may be learned by examination in a specific case. The specimens here collected are from the 1600-ft. level of the Leonard mine, Butte, Montana.

No. 1 shows quartz and pyrite in intimate intergrowth, surrounded by enargite. From field observations and study of many polished sections the quartz-pyrite intergrowth is known to belong to the first of several periods of mineralization. Petrographic study of the wall rocks shows these minerals to exist in two occurrences; (1) as a replacement of the normal quartz monzonite; (2) as primary minerals deposited in fractures. The replacement type is by far the most important in the Butte veins. Enargite is seen to be surrounding and apparently replacing the quartz-pyrite. It is seen that the contacts between the quartz and pyrite veins are continued out into the enargite. This is more clearly brought out in No. 2 which is an enlargement of a part of the field of No. 1 as indicated by the white dotted line. Here the contacts are clearly traced into the surrounding enargite. The dark spots seen in the enargite within the preserved contact lines are quartz or pyrite, depending on which of the two earlier minerals has been replaced.

No. 3 shows covellite replacing enargite, and, to a less degree, pyrite. No. 4 shows angular fragments of enargite cemented in a matrix of covellite. The covellite has subsequently been brecciated, and its cementing material is chalcocite. In this one photo-

graph two movements of the vein are clearly illustrated. The first fractured enargite which was cemented with covellite; the second brecciated covellite which was cemented with chalcocite.

No. 5 and No. 6 show the development of bornite in chalcocite. The peculiar meandering occurrence of the bornite is due to the inherited structure of the early quartz-pyrite mineralization (see No. 1 and No. 2). A careful study of the Butte ores leads to the opinion that the deep seated chalcocite here shown was deposited in colloidal form from ascending alkaline solutions. Where pyrite in small residual fragments remained from earlier periods of mineralization, it induced the formation of bornite and chalcopyrite (principally the former) by a reabsorption of the iron from the pyrite. This iron combined with the colloidal chalcocite *in situ* to form bornite, as seen in the accompanying microphotographs.

No. 7 shows chalcopyrite developing contemporaneously with chalcocite along the contact of enargite and covellite. In this case chalcocite is attacking the covellite which contains much finely disseminated residual pyrite. The replacing solutions being sluggish in the deep re-entrant angles of the enargite they failed to carry off the iron from the decomposed pyrite. This iron combined with the colloidal chalcocite to form chalcopyrite.

No. 8 shows chalcocite replacing enargite and covellite. The later mineral is clearly seen to be eating in along the cleavage plains of the covellite.

No. 9 and No. 10 show the two end points of the replacement of covellite by chalcocite. No. 9 shows the insipient stage of chalcocite replacement, which is eating in along the cleavage planes of the covellite. No. 10 the last stage of replacement; only narrow needles remain to mark the former positions of the covellite plates. The former outline of the covellite fragments is easily distinguished by the distribution of the residual needles.

No. 11 illustrates what I believe to be conclusive proof of the earlier colloidal condition of the chalcocite, and hence that it was derived from upward circulating alkaline solutions. The oblique systems of light parallel lines are not artificially developed but are the result of the action of moisture in the atmosphere. It will be observed that the main mass of the chalcocite exhibits a dirty spotted appearance. This is due to tiny specks of bornite and other impurities which are quickly tarnished by moisture. It will be observed that the larger of these spots are cut off or pushed aside by the lighter lines. These lines indicate the crystallographic planes of chalcocite and it is assumed that there was a tendency of the chalcocite to purify itself along these lines when crystallization took place. It is known that chalcocite crystallizes from the colloidal state by the release of hydrogen sulphide¹¹; and the phenomenon here shown is the result of such action.

PLATE I.

No. 12 shows the principal copper minerals of the several periods of mineralization: (1) enargite; (2) covellite; (3) chalcocite (also bornite and chalcopyrite); (4) a purer chalcocite which cuts through and replaces the first generation of this mineral¹².

The Scope of the Science

Only a few of the most important points have been touched in the foregoing descriptions, but it is hoped they may serve to illustrate some of the results which can be obtained. The application of the reflecting microscope to the study of ores will not act as a 'willow wand'. Results are not often casually obvious, but must be obtained by careful and often tedious study of many specimens. This growing science is not going to revolutionize mining geology and make it possible for the expert to sit in his office on the 18th floor and after examining a few chips of ore, give unerring advice as to the extent and richness of an ore deposit. It is confidently believed, however, that with this means of studying ore minerals the geologist has added another tool to his work chest. He may now square up the results of his field and petrographic study. He may know certainly what he previously only suspected regarding the relations of ore minerals; and may learn many valuable facts which he previously had to do without in deciding for or against a mining property.

This work is not going to solve problems for the successful ore treatment, but it will in many cases point out why a treatment fails. Much can be accomplished along the line of detailed metallurgical experimentation with individual ore minerals.

Growth of the Brass Industry

Charles F. Brooker, president of the American Brass Co., the world's largest copper consumer, said in a recent interview by the *Boston News Bureau*: "As an illustration of the growth of the brass business, it may be pointed out that the Coe Brass Manufacturing Co., of Torrington, Connecticut, had an output in 1864, its first year, of finished material of about 75,000 lb. per month, or 900,000 lb. for the year, and in 1869 it ran up to 100,000 lb. per month or 1,200,000 lb. for the year. Forty-three years later, 1912, the same mill turned out over 50,000,000 lb. of finished material, or four and one-quarter times each month as much as the yearly product of 1869. The consumption of copper was fairly estimated as having been 25,000,000 lb. in this country in 1864; in 1870 it was reckoned at 30,000,000 lb.; and in the year 1913 the domestic deliveries in the United States aggregated 767,000,000 lb., or 64,000,000 lb. per month. I remember being told in my early days that we must look to Baltimore alone, in this country, and then to England for our supply of copper."

Sulphur produced in the United States in 1913, according to the U. S. Geological Survey, was 311,590 long tons, valued at \$5,479,849, the greatest output in the history of the industry. This output was 8118 long tons greater than that of 1912 and showed an increase in value of \$223,427. In 1913 three states produced sulphur, namely, Louisiana, Texas, and Wyoming. The United States is rapidly gaining on Sicily, which at the present time is the leading sulphur-producing country in the world, and whose output for the year ended July 31, 1913, was 346,213 long tons.

¹²Reno Sales has given almost uncontrovertible geologic evidence showing that the deep seated chalcocite of the Butte district is due to the agency of ascending solutions. This evidence is strongly corroborated by work which I have done on the wall rocks by petrographic methods and on the ore minerals with the reflecting microscope. See, Reno H. Sales 'Ore Deposits of Butte, Montana', *Trans. Amer. Inst. Min. Eng.*, Aug., 1913, pp. 1523-1631.

Determination of Flue-Dust Losses

By T. NEILSON and L. LARSON

The determination of flue-dust losses in metallurgical works is one of prime importance to all smelting companies and the method employed in arriving at a correct solution of the problem is valuable to the chemist and metallurgist.

Steptoe Valley Smelter

As a contribution to this subject we present the following description of the method adopted at the Steptoe Valley Smelting & Mining Co. smelter, embodied in the form of a report. For obvious reasons the actual results of flue-dust losses are not given. This, of course, does not detract from the value of the paper. Except in some minor details, originality is not claimed for the process, nor for the calculations involved.

The actual weight of flue-dust can be arrived at by determining the percentage of Cu in the flue-dust and

ground to fit, and after inserting the filter papers, the edges are sealed with a thin coating of paraffine.

DETERMINATION OF MOISTURE IN REVERBERATORY STACK GASES

SKETCH OF APPARATUS USED FOR EXTRACTING MOISTURE FROM GAS.

Note.—The gas samples were obtained by drawing the gas from the stack as shown in sketch above. The gas was drawn out very slowly, the moisture being extracted by the Geissler bulb, with attached CaCl_2 tube and the quantity of gas measured in carboy as shown. The moisture which has condensed in the tube AB was then driven into the Geissler bulb and CaCl_2 tube by drawing dry air through the tube. The bulb

TABULATED DATA

| Date of test. | Duration of test. | Litres of gas. | Gas temperatures. | | Moisture collected. gm. | Moisture per litre, gm. |
|---------------|-------------------------|----------------|-------------------|----------------|-------------------------|-------------------------|
| | | | Carboy, deg. F. | Stack, deg. F. | | |
| June 17, 1913 | 1:00 p.m. to 3:00 p.m. | 9.0 | 85 | 550 | 0.171 | 0.019 |
| " 18, " | 10:25 a.m. to 3:12 p.m. | 11.0 | 78 | ... | 0.241 | 0.0219 |
| " 19, " | 9:20 a.m. to 2:57 p.m. | 10.0 | 80 | ... | 0.230 | 0.023 |

Average moisture = 0.0214 gm. per litre of reverberatory stack gas.

1 litre of H_2O vapor weighs 0.804 gm. at N. T. P.

Then $0.0214 \text{ gm.} \div 0.804 \text{ gm.} = 0.0266$ litres of H_2O vapor extracted from each litre of gas.

Each litre of gas measured + moisture extracted = volume of original gas = $1 + 0.0266 = 1.0266$ litres.

Therefore, percentage of moisture = $0.0266 \div 1.0266 = 2.59\%$.

DETERMINATION OF CO_2 , CO , AND O_2 , AND CALCULATIONS OF THE WEIGHT PER VOLUME OF REVERBERATORY STACK GAS

TABULATED DATA

| Date of test | Time. | Analyses— | | | Stack Temp. gas temp., sample. | | Remarks. |
|---------------|------------|-----------------|----------------|---------------|--------------------------------|------|--|
| | | $\text{CO}_2\%$ | $\text{O}_2\%$ | $\text{CO}\%$ | F. | F. | |
| June 20, 1913 | 9:00 a.m. | 5.9 | 15.7 | 0.0 | 550 | 80 | Reverberatories No. 2, 3, and 4 in operation |
| " " | 10:10 a.m. | 4.5 | 16.5 | " | " | " | " |
| " " | 10:20 a.m. | 5.0 | 15.0 | " | " | " | " |
| " " | 10:40 a.m. | 3.8 | 16.8 | " | " | " | " |
| " " | 10:50 a.m. | 3.8 | 16.6 | " | " | 85 | " |
| " " | 11:10 a.m. | 4.5 | 15.7 | " | " | " | " |
| " " | 11:18 a.m. | 4.2 | 15.3 | " | " | " | " |
| Averages | | 4.53 | 15.94 | 0.0 | 550 | 82.5 | " |

using that ratio to the weight of Cu which is found in the test.

The investigation is divided into several parts:

1. Determination of moisture in gases.
2. Determination of CO_2 , CO , and O and calculations.
3. Velocity determinations by Pitot tubes and calculations.
4. Determination of flue-dust and Cu in gases.

The average percentage of SO_2 and SO_3 was so slight that it was left out of calculations.

In order to make an air-tight joint in the apparatus used in Part 4, the faces of the two glass funnels are

and tube were weighed before and after the test, the difference being the weight of H_2O extracted.

Note.—The gas samples were drawn from stack and analyses made with an Orsat and an Allen-Moyer gas apparatus. The samples taken for analysis were 100 c.c., but the moisture in each sample was 2.66 c.c., as determined by the moisture test. During the process of measuring the samples, this moisture condensed so the volume of the original sample was 102.66 c.c. Therefore, the correct percentages must then be calculated from 102.66 c.c.

Thus, calculating back: $4.53\% \text{ CO}_2 = 4.41\%$

$15.94\% \text{ O}_2 = 15.55\%$

$2.66 \text{ c.c. H}_2\text{O} = 2.59\%$

N by difference = 77.45%

Total = 100.00%

CALCULATIONS OF THE WEIGHT PER VOLUME OF REVERBERATORY STACK GAS

| | | | |
|--------------------------------------|-----------------------------|-----------------------|--|
| At N. T. P. 1 litre | CO ₂ = 1.965 gm. | From average analysis | CO ₂ = 0.0441 litre × 1.965 gm. = 0.08665 gm. |
| " " " | O ₂ = 1.429 " | " " " | O ₂ = 0.1555 " × 1.429 " = 0.2222 " |
| " " H ₂ O vapor = 0.804 " | " " " | " " " | H ₂ O = 0.0259 " × 0.804 " = 0.02082 " |
| " " N = 1.250 " | " " " | " " " | N = 0.7745 " × 1.250 " = 0.96812 " |

At N. T. P., total weight of 1 litre reverberatory stack gas = 1.29779 "

1 cu. ft. = 28.3 litres. Then $28.3 \times 1.29779 = 36.7249$ gm. per cubic foot.

$36.7249 \div 453.6 = 0.08096$ lb. = weight per cu. ft. of reverberatory stack gas at N. T. P.

VELOCITY TESTS AND CALCULATIONS OF VOLUME OF GAS PASSING UP REVERBERATORY STACK PER DAY

Pitot tube readings were taken across the stack at a point 16.5 ft. above the top of the gas inlet to the stack. The average of several sets of these readings was used in the velocity calculations. Several sets of Pitot readings were also taken in the inlet to the stack and the average of these was used in a separate velocity calculation as a check.

STACK VELOCITY CALCULATIONS

Average Pitot tube velocity reading in stack = 0.136 in. H₂O.
0.08096 lb. = weight of 1 cu. ft. reverberatory stack gas at 32°F. and 760 mm.

$$\frac{P_1}{P_0} = \frac{W_1}{W_0} \text{ or } P_1 W_0 = P_0 W_1 \text{ where } P_0 = 760 \text{ mm. } P_1 = 610 \text{ mm.}$$

$$W_0 = 0.08096 \text{ lb. } W_1 = \text{wt. cu. ft. gas at 610 mm. and 32°F.}$$

$$W_1 = \frac{P_1 W_0}{P_0} \text{ or } W_1 = \frac{610 \times 0.08096}{760} = 0.06498 \text{ lb.}$$

$$\frac{W_1}{W} = \frac{460 + T}{492} \text{ or } W = \frac{492 \times W_1}{460 + T} \text{ where } T = \text{stack temp.} = 590^\circ\text{F.}$$

$$\text{and } W = \text{wt. of cu. ft. of gas at } 590^\circ\text{F. and 610 mm.}$$

$$W = \frac{492 \times 0.06498}{460 + 590} = 0.03044 \text{ lb.}$$

62.4 lb. = Weight of a cubic foot of water.

$$\frac{62.4}{W} = \frac{62.4}{0.03044} = 2049 \text{ factor to convert column of H}_2\text{O to stack gas at } 590^\circ\text{F.}$$

$$\frac{2049}{12} \times 0.136 \text{ in.} = 23.21 \text{ ft. of gas} = h.$$

$$V = \sqrt{2gh} = 8.02 \sqrt{h} = 8.02 \times 4.81 = 38.5 \text{ ft. sec.} = \text{velocity of gases in stack.}$$

$$\text{Diameter of stack} = 20 \text{ ft. Area} = \pi r^2 = 3.1416 \times 10^2 = 314.16 \text{ sq. ft.}$$

$$314.16 \times 38.5 \times 60 \times 60 \times 24 = 1,045,021,824 \text{ cu. ft.} = \text{volume of gas passing up stack per 24 hours.}$$

STACK INLET VELOCITY CALCULATIONS

Average Pitot tube velocity ready in stack inlet = 0.2446 in. H₂O.

Stack temperature = 560°F.

Other figures and calculations same as above.

From calculations, velocity of gases in inlet = 51.0 ft. per second.

$$\text{Area of inlet } 28.11 \text{ ft.} \times 8.5 \text{ ft.} = 238.9 \text{ sq. ft.}$$

$$238.9 \times 51.0 \times 60 \times 60 \times 24 = 1,052,688,960 \text{ cu. ft.} = \text{volume of gas passing through stack inlet per 24 hours.}$$

Note.—Three reverberatory furnaces, No. 2, 3, and 4, were in operation during these tests.

METHOD OF DETERMINING THE AMOUNT OF FLUE-DUST AND COPPER IN GASES AND METHOD OF CALCULATING VALUES ESCAPING

METHOD OF TEST

Gas was drawn from the stack at a point 16.5 ft. above the top of gas inlet to stack, as shown in sketch. The filter was composed of three filter papers held between two glass funnels placed face to face. The gas was passed through three bottles containing dilute HNO₃ in order to catch any copper

which might escape the filter papers. From 25 to 35 cu. ft. of gas was taken for each test.

After each test the amount of flue-dust collected was de-

APPARATUS FOR DETERMINING FLUE-DUST.

terminated. The copper content in the acid bottles, if any, was added to the copper in the flue-dust for total copper in sample.

METHOD OF CALCULATING

Sample of gas = 33.67 cu. ft. at 70°F. and 610 mm. Average stack temperature = 555°F.

V = volume at 70°F. and 610 mm. pressure = 33.67 cu. ft.

V₁ = volume at stack temp., 550°F. and 610 mm. pressure.

$$\frac{V}{V_1} = \frac{T}{T_1} \text{ where}$$

$$T = \text{absolute temperature of gas} = 460 + 76 = 536^\circ\text{F.}$$

$$T_1 = \text{absolute temperature of stack} = 460 + 555 = 1015^\circ\text{F.}$$

$$\frac{33.67}{V_1} = \frac{460 + 76}{460 + 555} \text{ then } V_1 = \frac{33.67 \times 1015}{536} = 63.75 \text{ cu. ft. gas at stack temp. and 610 mm.}$$

Moisture in gas (as found) = 2.59%, which correction must be added.

Then $63.75 \div 0.9741 = 65.44$ cu. ft. volume of gas sample, including moisture at stack temperature.

Flue-dust collected from gas sample = x grams, containing y% copper.

Flue-dust per cubic feet = $x \div 65.44$ grams.

From previous calculations, 1,045,021,824 cu. ft. gas passes up stack per 24 hours.

Then $1,045,021,824 \times (x \div 65.44) \div 453.6 = \text{pounds flue-dust per 24 hours.}$

Ore and tailing treated by the Zinc Corporation, Broken Hill, New South Wales, in April amounted to 13,751 and 29,000 tons, respectively, producing 3820 tons of lead concentrate by water concentration, and 6805 tons of zinc concentrate by flotation. The gross value of these products was \$220,000, and profit \$53,000.

A dry season in Colombia has resulted in the Pato dredge being shut down for about two months. Rain has commenced, and from June the dredge should yield \$50,000 per month for some time. W. A. Prichard reports that drilling has added 100 acres to the proved area at Pato.

Work at the new platinum deposits in Westphalia, Germany, is well under way, and 60 miners are developing the area.

The Murex Process in a German Works

By JAMES M. HYDE

At the Bergwerks-Wohlfahrt near Clausthal, in the Harz mountains of Germany, the Murex process of concentration, controlled by the Murex Company, Ltd., of London, is being used for the separation of very fine galena from a slime tailing containing much heavy spar, barite. The installation is of particular interest because it is very profitably treating material which no other type of concentration process has been able to handle satisfactorily.

The ore treated is from the Wohlfahrt mine, a gov-

3. Spathic iron ore, containing galena in spathic iron with quartz and barite.

These three classes of ore are stored in separate bins as they come from the mine, and are milled separately as they are of such widely different character as to require different adjustments of the jigs and tables.

The coarser part of the ore, after crushing and screening, is fed to revolving picking tables and divided into three products. Rich lead ore is picked out and sent to the smelter. The lumps of high-grade barite are picked out and sold to paint manufacturers. The remainder of the ore is further crushed and jigged and tabled for the production of a lead concentrate.

Treatment of Slime

The slime produced in the various crushing operations contains so much of the heavy spar that it has been found impossible to satisfactorily recover the lead content by any of the forms of table, vanner, or buddle concentration used in the plant. As local conditions make it necessary to discharge no slime into the streams, the slime tailing has been diverted to tailing ponds, in which it has been settled by the addition of a small quantity of magnesium chloride. This salt is a cheap by-product of the potassium salt works, which are not far away. The accumulated slime contains from 10 to 11% of lead and is high in silver.

The mill also produces a fine sand middling which contains from 4 to 7% of lead which is not recoverable by water concentration because of the large amount of heavy spar present.

The slime is dug from the pond and hauled to the mill. The feed for the Murex plant is made up of about 33 to 40% of slime to 60 to 67% of middling. The dry feed is fed into a trough mixer of the concrete mixer type, wherein water is added to make a pulp containing about one part of water by weight to one part of ore. From the mixer it flows to a little tube-mill consisting of a barrel containing small pebbles to completely break up the rough balls of dried slime and produce a homogeneous pulp.

To the pulp is then added a small quantity of a mixture of oil, pitch, resin, and finely ground magnetite as it flows to a cylindrical oiling device in which the galena is oiled and made ready for electro-magnetic separation.

The barrel in which the pulp is agitated and oiled is a tube-mill-like sheet iron vessel, 1.2 metres in diameter and 3.5 metres long. This is lined with beechwood blocks, 14 cm. high, placed on end so that the wear comes on the end of the grain. The mixer revolves at about 20 r.p.m. and contains a mixture of pulp, the oiling mixture, small flint gravel, and steel

A, OILING BARREL; B, LAUNDER; AND C, ELECTRO-MAGNET.

ernment property, and is divided by the management into three classes:

1. *Schwarz ore*, which is a mixture of a dark schist and galena, which, by hand picking, jigging, and tabling, yields a lead concentrate containing approximately 70% of lead.

2. *Weisse ore*, which is a mixture of barite, schist, quartz, and galena. The most carefully hand-picked galena from this will not carry more than 40% of lead, the jig and table concentrates average about 58% of lead. In this type of ore the galena is filled with minute veinlets of quartz, necessitating such fine grinding as to yield a high percentage of slime.

screen punchings. The steel punchings become coated with the oily mixture and assist in oiling the fine galena. The gravel seems to be chiefly useful in keeping the thick charge open and flowing.

The oiling barrel works continuously, discharging the oiled pulp through a slotted discharge and thence to a screen on the head of a shaking launder feeder. This screen catches any chips, gravel, or punchings which may escape from the oiling barrel. The shaking launder feeds the pulp in a thin agitated stream beneath a specially designed electro-magnet which is enabled to separate the oiled galena from the unoled gangue because of the finely ground magnetite contained in the oil.

Referring to the cut, which is reproduced from a photograph taken by me at the works on January 20, 1914: *A* is the oiling barrel, *B* the shaking launder which feeds the oiled pulp under *C*, the electro-magnet. The take-off belt of the electro-magnet travels in the direction indicated by the arrow, the concentrate being discharged into a hopper which does not show in the photograph. A jet of water is sprayed on to the belt to facilitate the discharge of the concentrate. The long handled spoon leaning against the housing of the mixer is used to reach into the mixer and take samples of the pulp for inspection. When the screen punchings are properly coated with the oiling mixture the work is proceeding satisfactorily. When they become bare, the recovery drops and it is necessary to increase the rate of oil feed, or regulate the percentage of resin in the oil mixture. It is found that on this ore the process works best at a temperature of 17°C. to 20°C. The pulp is heated to this temperature by exhaust steam.

Concentration Results

The feed to this plant contains from 6 to 8% of lead. The concentrate produced assays from 56 to 62% lead and about 1.13% silver. The tailing averages about 1.1% lead. A tube-mill is being installed to pulverize the middling, as it is found that the portion which passes through a one-half millimetre screen, assays 0.8% lead, while the coarser stuff goes as high as 5%. The plant is now making a recovery of about 80% and it is confidently expected that the recovery will be 85% or better after the tube-mill has been put into operation.

The mixing barrel contains about 150 kg. of iron shot or screen punchings from 4 mm. to 6 mm. diameter, and 150 kg. of 10 mm. to 20 mm. flint or quartz pebbles. The monthly consumption of these materials amounts to about 5 kg. of iron and 5 to 10 kg. of pebbles.

In treating 9000 kg. of ore per day 20 kg. of paraffine oil and 40 kg. of pitch, or bitumen (both from the distillation of brown coal) are used with 0.2 kg. of resin and 72 kg. of finely ground magnetite. The cost at the works of these materials per metric ton is reported to be: paraffine oil, 140 marks (\$33.60); pitch, 115 marks (\$27.60); resin, 320 marks (\$76.80); magnetite, 25 marks (\$6) in large lumps as delivered:

41 marks (\$9.84) ground ready to use. The cost of labor for running and repairs is reported to be 0.98 mark per metric ton treated, and the cost of power, 0.4 mark. Reducing these costs to terms of American currency and short tons the principal items figure out as follows:

| | |
|---------------------------------------|----------|
| Oil 4.4 lb. @ \$0.0153 | \$0.0673 |
| Pitch 8.8 lb. @ \$0.0125 | 0.1100 |
| Resin 0.44 lb. @ \$0.0349 | 0.0153 |
| Magnetite 15.84 lb. @ \$0.00447 | 0.0708 |
| Labor | 0.2064 |
| Power | 0.9877 |
| Total | \$0.5575 |

Although the plant is running for only one shift and treating but nine to ten tons per day, the total cost of treatment in this department is reported by the management to be but 2.45 marks, or, approximately \$0.59 per metric ton. The same amount of labor would handle a number of units of greater capacity than the one in use. The power costs would also be proportionately lower. The profits of the operation have been so satisfactory that the capacity of the plant is to be doubled and the ores of other government-owned mines are to be carefully tested to determine how widely the process may be used on the Crown properties.

Comparison with Other Processes

The Murex process differs from the other oil concentration processes in that it is not necessary in using it to produce those conditions under which the oiled mineral will float. This permits great latitude in the application of the process. Practically all of the separations made by other oil concentration processes can be equally well made by this process. In addition, it is possible to make certain separations which have previously been considered to be practically impossible. Thus copper carbonates and oxides can be satisfactorily concentrated from either quartzose or calcareous gangues. Blende and galena can be separated from heavy spar, also from each other, and from pyrite. In certain cases chalcopyrite can be separated from pyrite, and lead carbonate can be concentrated from the gangues with which it usually occurs. Material of two or three millimetres diameter may be successfully treated by the Murex process if the mineral is all free.

The methods of agitation and of removing the concentrate result in the entanglement of practically no clean particles of gangue. Hence it is possible to make very high grade products. Entirely volatile cheap oils may be used, permitting the concentrate to be freed of its oil and magnetite at little cost where blende is being recovered. The bulk of the oily mixtures generally used consists of very cheap oils such as crude petroleum, residuums, and creosotes. The American equivalents of the oily materials used in Germany cost much less than the German products. Roasted pyrite may be converted into magnetic oxide of iron by being heated in the presence of a reducing agent. This material may be used in place of natural magnetite. It has the

advantage of being more cheaply ground than the natural magnetite. Fairly magnetic pyrrhotite, which occurs in many mining regions can probably also be used instead of magnetite.

Much skill may be exercised in blending oil mixtures, in governing the type of agitation used, and modifying conditions of pulp thickness, acidity, alkalinity, and temperature, in such manner as to make commercially successful differential separations which have hitherto

been considered practically impossible. The apparatus used, while simple, is the result of careful study over a period of years during which the conditions necessary in the various operations of the process have been mastered. The process is not expected to be a panacea for all the troubles of the anxious millman but it should fill an important place in the rapidly developing art of ore dressing, and is a step forward in the treatment of certain ores.

Rock-Drill Repair Costs

By C. K. HITCHCOCK, JR.

*In an endeavor to compile accurate and definite information on the life of rock-drills, and the cost of keeping them in repair, I have collected certain data, of which the condensed results are here given. These data are unfortunately incomplete, as the work was cut short by labor troubles. However, the results obtained are so significant as to lead me to believe that they may be of interest to others.

One great obstacle to obtaining data on the life of a rock-drill is the manner in which repairs are made. I refer to the common method of taking worn parts from a machine, and, after truing them up, putting them into some other machine, which is in condition to use them. It is often possible to true up a part several times before having to throw it away, and each time this is done it may be put back into a different machine, so that in a comparatively short time the original parts of a drill may be widely scattered. It is probably true that each one of a group of machines which are at work on the same job for two years will, at the end of that time, consist principally of new parts and parts taken from other machines.

Fortunately, the keeping of the costs to be discussed

TABLE I. REPAIR COSTS OF 2 $\frac{3}{4}$ -IN. DRILLS.

| Drill | Days in use. | | | | | | | | | |
|---------|--------------|---------|---------|----------|----------|----------|---------|---------|---------|--|
| | 25 | 50 | 75 | 100 | 125 | 150 | 175 | 200 | 225 | |
| A | \$ 1.00 | \$ 1.25 | \$ 1.50 | \$ 2.40 | \$ 3.00 | \$ 7.05 | \$10.80 | \$11.40 | \$21.80 | |
| B | 1.75 | 7.50 | 7.00 | 8.75 | 12.00 | 16.25 | 21.80 | | | |

| | \$ 1.74 | \$ 3.19 | \$ 4.74 | \$ 7.88 | \$ 14.95 | \$ 21.95 | | | | |

in this article was started with a group of 20 new drills. Of this number, 5 did not see enough service to make their record of value, whence the data here given relate to 15 machines. They were of a well known make, having 2 $\frac{3}{4}$ -in. pistons, and were put to

work during the spring and summer of 1912. The records were kept by the month, and the total repair cost of each drill, including both labor and material, but not including mountings or connections, was plotted at the end of each month on a chart against the total number of days, of two shifts each, during which the drill had worked from the time it was put into commission. From this chart was scaled the cost for each drill for each period of 25 days, as recorded in Table I. The average of these amounts is shown at the bottom of Table I, and is plotted in Chart 1 by a

solid line. The service varied a good deal, as will be seen, ranging from 150 days to 325 days each. This variation does not indicate poor service, but is explained by the fact that the drills were not all put to work at the same time, and also that the number of drills on hand was somewhat in excess of the actual number in use, so that some were always idle, whether in the repair shop or not. Good average results, therefore, were obtained for only 150 days, beyond which

*School of Mines Quarterly.

time the averages are incomplete and inconsistent, and lose all significance. It should be added that most of the smaller repair parts for the drills were made in the mine shops, but that the larger parts were bought from the makers of the drills. Also, when a machine was sent to surface, it was replaced at once by another, no serious attempt being made to keep the same machine in the same working place.

It is a curious fact, though probably only a coincidence, that the average repair cost for the first 150 days approximates closely the following geometrical progression, having 1.66 as a ratio: 1.74, 2.89, 4.80, 7.96, 13.22, 21.95. This progression is plotted as a dotted line on Chart 1, the solid line representing the actual repair cost. Obviously, if the repairs should follow the dotted line to, say, 200 days or farther, the expense of keeping up these drills would be so great as to indicate that they had practically gone all to pieces, which, of course, is contrary to general experience. I believe, therefore, that beyond 150 or 175 days the repair cost graph, if it could have been continued, would have become in time approximately a straight line, having such inclination as to represent a cost of \$10 or over for each 25 days, provided all the machines were kept in commission. This approximation is based partly on the fact that the actual repairs between 100 and 150 days were about \$7 for every 25 days, and partly upon the performance of another size and type of drill, which I shall now discuss.

The drills of the second group were larger, having a 3 1/4-in. piston. Eight new ones were put to work in 1911, and the records were kept in the same way as

thus produced is more irregular than that for the smaller drills, but a straight line joining the two ends averages the irregularities fairly well and represents a cost of practically \$5 per 25 days. Of course this is hardly a fair comparison, and for the purposes of this discussion, it would have been desirable to have had the drills repaired and kept in commission. The immediate cost would have been between \$60 and \$80, with a resulting average increase of \$8 or \$10 at the 175-day period. How much of this increase would have shown as an increase throughout the remainder of the graph, is, of course, uncertain, but probably enough to have brought the average beyond 175 days up to \$10 for every 25 days.

Again, from other data too incomplete to give here, obtained from such of another group of drills of the same size and type as had been in commission for from three to five years, the repairs amounted to \$7.50 every 25 days. This rate, of course, is based on the best machines of the lot, the poor ones having been discarded. If all had been kept at work, there is evidence that the cost would have been nearly double.

The practical application of such data as here given should be obvious. For instance, having obtained or assumed the average repairs for a certain lot of machines at work on a given job, and having plotted it on a chart, it would then be an easy matter, even for the

TABLE II. REPAIR COSTS OF 3/8-IN. DRILLS.

for the 2 3/4-in. machines. But after two of the drills had worked about 160 days, their cylinders cracked and they were put out of commission. The repair costs and service of the remaining six drills for two years is given in Table II, and is plotted in Chart 2. The graph

repair man, to see how things were going, simply by plotting the record of each individual machine, month by month, alongside the average. Some machines, at times, will show up badly beside the average, for some good cause, while others will compare poorly from some inherent defect, and will be a constant source of expense. By a study of the chart, in connection with the care of the drills, economy and efficiency could both be served, either by culling out the worst offenders, or by giving them such a thorough rejuvenation as would tend to cut down their maintenance expense.

Gases Found in Coal Mines

In discussing gases found in coal mines, which also bears on metal mining to some extent, George A. Burrell and Frank M. Seibert, in U. S. Bureau of Mines Miners' Circular No. 14, summarize their more important statements as follows:

Pure, dry, outside air contains about 21% oxygen and 79% nitrogen all over the globe.

All mine air contains water vapor, the proportion depending chiefly upon the temperature of the air and the amount of water present along the passageways.

A mixture of methane and air is explosive when it contains 5.5 to 13% of methane, but some burning will occur in a mixture that contains considerably less or more methane than these proportions.

Methane, or any other gas, once thoroughly mixed with air, will not separate from the mixture.

Ordinary fire-damp has no odor.

Black damp is not carbon dioxide alone, but a mixture of carbon dioxide and nitrogen.

Lights grow dim or go out in atmospheres containing black damp because of the low proportion of oxygen in the atmospheres, and not because of the presence of carbon dioxide (CO_2).

The effects on man of the black damp in atmospheres in which lamps do not burn are sometimes due to the carbon dioxide present, sometimes to the lack of oxygen, and sometimes to both of these causes.

An ordinary wick-fed flame goes out when the proportion of oxygen in mine air is reduced to about 17 per cent.

An acetylene flame goes out when the proportion of oxygen is reduced to about 12 or 13 per cent.

All flames become dimmer when the proportion of oxygen becomes less than that in outside air.

Air may be what is termed chemically pure and yet cause distress if its temperature is high and much moisture is present. This distress is heightened if the air is motionless.

The most dangerous gas in after-damp is carbon monoxide (CO).

An atmosphere must not be assumed to be non-explosive because it does not contain enough oxygen to support the combustion of an oil-fed flame.

A lamp flame may burn fairly well in an atmosphere that contains a fatal proportion of carbon monoxide. The presence of fatal proportions of this gas is not indicated by the appearance of the flame.

Mice or birds, preferably canaries, should be used by men not wearing breathing apparatus when exploring mines after explosions or fires, to ascertain the presence of gas in appreciable quantities.

Ore reserves of 53 mines on the Rand, controlled by 10 mining concerns, amount to 92,569,045 tons of fully developed ore. Adding the partly opened ore, *The South African Mining Journal* makes a total of 115,000,000 tons, worth approximately \$744,000,000.

Emergency Gate

By P. B. McDONALD

This emergency gate for ore-chutes, underground, is a simple $\frac{3}{8}$ -in. iron plate which is supported in such a manner that it may be dropped over the end of the chute, and thus stop the ore in case an obstruction prevents the quarter-pan from closing down. The mouth

of an ore-chute is a precarious place when the ore gets stuck, and barring or blasting is sometimes necessary to loosen the mass inside. The trammers are often careless and reckless, and many accidents occur. The chute here shown is designed for soft, fine ore.

Capital outlay on electricity supply in greater London, with a population of 7,252,963 persons, totaled \$126,516,340 to the end of 1912; and the outlay on generating machinery amounted to \$39,220,050. It is proposed to unify all the systems. Comparison of the electric systems of the largest cities of Europe and the United States is as follows:

| Cities | Population. | Area square miles. | Kilowatts connected. | Units used per capita. | Per cent. |
|----------|-------------|--------------------|----------------------|------------------------|-----------|
| London | 7,252,963 | 693 | 523,865 | 125 | 4.65 |
| Paris | 2,800,000 | 31 | 226,890 | 27 | 10.35 |
| Berlin | 2,200,000 | 24 | 225,721 | 117 | 3.15 |
| Hamburg | 1,000,000 | 30 | 99,031 | 42 | 6.25 |
| New York | 4,754,000 | 131 | 782,682 | 369 | 5.28 |
| *Chicago | 2,185,283 | 191 | 545,235 | 425 | 2.21 |
| Boston | 1,951,907 | 597 | 175,116 | 409 | 5.48 |

*Including traction.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

The Rand Banket

The Editor:

Sir—Mr. Horwood has so thoroughly studied the Rand banket and has discussed the character of the deposits and the introduction of the gold from so complete a survey as to leave scarcely any points uncovered. Rarely has a writer on an ore deposit brought to bear upon its study so much in the way of observation and reading. No line of attack seems to have been left untried. As I run over in my mind other recent contributions from those actually engaged in mining, only one paper readily occurs in which, in the same thorough-going way, a great district has been so completely investigated in its various geological features. This is the study of the Butte vein system by Reno H. Sales, as published in the *Bulletin* of the American Institute of Mining Engineers last August. The two papers cannot but make those teachers of geology, who expound the lore of ore deposits to their students, wish that their hearers, when actively engaged in mining in their later years and when confronted from day to day with the wonderfully interesting phenomena of vein formation, would oftener plot and describe the facts and ponder the causes.

Mr. Horwood speaks convincingly regarding the introduction of the gold. Indeed, it has seemed to many observers who have reflected carefully upon the suggested placer explanation and who have studied thin sections of the ore, that pyrite could hardly be expected to survive the oxidizing conditions surrounding 'pebbles on the beach.' By so clearly demonstrating the origin of the rounded masses of the pyrite from the replacement of quartz pebbles, and the irregular bits of the sulphide of iron by replacement of the conglomeratic matrix, the evidence of the pyrite is made a strong argument for the introduction of the gold in solution. The black edged pebbles, the wholly black ones, and the milky white ones are all excellent corroborative phenomena, which have been interpreted with care and skill.

The presence of the carbon is a peculiar and interesting feature and makes of importance those comments on other cases in which similar observations have been recorded. One is ordinarily over-inclined to think of hydrocarbons in connection with the products of igneous action. Reference may be made to the careful experiments of Arthur W. Wright, of Yale, upon the extraordinary quartz of the famous pegmatite at Branchville, Connecticut, which is so rich in carbonic acid inclusions. Thin sections of the quartz fairly teem with cavities containing this compound in both liquid

and solid state. Professor Wright crushed the quartz in a vacuum under a bell-jar by an ingenious pestle and mortar arrangement, working like a piston in an air-tight cylinder. He thus set free the gas under such conditions that he could confine and analyze it. Each time that he passed his samples of gas through his apparatus he secured an appreciable tarry residue of some form of bitumen or heavy hydrocarbon. Now there can be little doubt that the pegmatite is a product of the granite intrusives which are abundant in southwestern Connecticut, and that gas and bitumen came off with them. The general process is closely akin to the one favored by Mr. Horwood, but the pegmatites, of course, involve a great richness in the components of feldspar, quartz, and, in the Branchville instance, of minerals containing lithia.¹

Wm. Libbey, of Princeton, has reported spectroscopic evidence of burning hydrocarbons in the gases freed from the lake of molten lava in the famous Hawaiian crater.² Graphite in pegmatite veins is quite common in the southeastern Adirondacks, and was for many years in the last century mined near Ticonderoga. The old workings are said to go down six or seven hundred feet.

Carbon or hydrocarbons are thus reported, or are actually known, today in several cases of igneous or aqueo-igneous products in addition to the instances cited by Mr. Horwood. Carbon in any condition short of the extremely resistant forms of the diamond or graphite, could hardly fail to be a sufficiently strong reducing agent to precipitate so sensitive a metal as gold. Apparently the two would be antagonistic if in solutions or vapors at the same time and place.

I would again remark, in closing, that the hope is to be entertained that Mr. Horwood's paper will encourage similar close observations on the part of others.

Prospecting and Government Aid

The Editor:

Sir—In the issue of May 2, under the caption of 'Prospecting and Government Aid,' F. L. Ransome gives some reasons why the members of the U. S. Geological Survey are unable to meet all the demands that are made upon them for examinations, reports, consultations, etc., by the owners of all kinds of prospects, mines, and near-mines from all over the country. The chief reason advanced, strange as it may seem, for not doing all this beneficent work is not because it is not a part of the Government's function to render such service to individuals, but simply because, from lack of funds, they are unable to get around to all solicitors. Mr. Ransome informs us that "The new district of Rochester, Nevada, was visited by a geologist a few weeks after its discovery, and a brief account of its geology and the character of its deposits was fur-

¹*American Journal of Science*, March 1881, p. 209.

²*Ibid.*, May 1894, p. 371.

nished the press before the geologist returned from the field." This was lightning work, and I suppose I will soon hear of efforts being made to secure appropriations for the Survey so that every prospector, or certainly every prospecting party, may have attached a geologist of the Survey, so that it will not even be necessary to send to town and have such a member rushed to the ground.

But why should the prospector or the rich mine-owner ask and receive gratis from the Government a service that costs a handsome sum, and if done by private practitioners or the miners themselves would have to be paid for? Why isn't it just as logical and justifiable for the Government to furnish me the necessary legal talent to defend a civil suit at law; or supply me with the capital necessary to develop a mine or ranch; or, in fact, supply me with any requisite or service my fancy may crave or my necessities may require? How many instances are there where geologists of the Geological Survey have been set at work in mines, and in particular districts where the Government didn't own a single acre of land and had not the vestige of title to any mine, to solve if possible the complex and often baffling problems that have confronted such individual miners or districts, and to the profit of the individual only? Well, it wouldn't be wise, or perhaps safe, to say just how many times this thing has been done. But the reasons are given for all this activity in that ancient and hoary-headed plea that "The sound practical application of geology to mining must rest upon a solid substratum of scientific research, and demands such training as rigorous scientific investigation can alone supply." I remember, years ago, in my student days, this same ancient and overworked plea was doing overtime then, I have noted no diminution in its activities since, and it is altogether likely that on down, in the long roll of the centuries, it will still be invoked for a similar service.

After an existence verging on half a century, perhaps it might be well to inquire just how many positive definite principles the Survey, at an expenditure of many millions of dollars, covering many different fields, and with the best brains and talent obtainable, has been able to add to the 'Science of Ore Deposits.'

As I glance hastily over the numerous and ponderous toms that stand as evidence of the patient and painstaking labors of their talented authors, I am deeply impressed with the magnitude of the tasks attempted. But when I casually brush the dust off the backs of any one of eighty or ninety elaborate monographs and professional papers which have been issued by the Survey, chiefly on the questions concerned with the nature and genesis of ore deposits and examine the contents of the works, I soon discover the following facts which are common to nearly all:

1. An accurate detailed account of the history of a particular district or locality, together with its exact geographical location; also everything about the streams, the roads, the forests, the deserts, the land-

scape, the scenery, the sunshine, the atmosphere, the people, and what they do and think, and nearly everything else that might prove interesting, entertaining, or possibly instructive and which occupies space.

2. A labored and elaborate description of the general geology of the district; and fortunate indeed is the geologist who has, or thinks he has, anything that is suggestive of an eruptive rock; because a fragment of eruptive rock, no matter how small its dimensions, is always large enough for the best geologist to lavish his utmost abilities upon when it comes to a description of the precious thing, at the same time straining the unabridged for names and terms sufficient and ponderous enough to do it with. What a fruitful field of speculation and mental exercise it is, to carefully inquire into the reasons why each little crystal contained in a particular rock came to be there, and what it is doing, and what would happen if some other mineral was present that is not.

3. Economic geology follows as a matter of course with an elaborate table of statistics showing the value and production of the district from the dawn of history to date. For this, of course, we are thankful. Then particular classes of ore deposits, or mines, are taken up and described by rule and line; every rock, every crevice, every seam, and every twist, bend, turn, regularity, and irregularity of the deposit, and every rock even remotely connected with it are described with marvelous detail. Having arrived thus far in our study we probably feel convinced that there has been some kind of ore deposit once in existence, and we are free to guess how much there is left of it. But no description of any ore deposit is complete without an inquiry into its genesis. And it must be admitted that when our true geologist sets himself the task of answering this question, he may always be expected to let himself out to the last link, and 'get up and hump himself.' The mineral *was* there—so much he has ascertained from his inquiries (and no competent and wise geologist will positively affirm more than this). Now how did it get there? Of course, so far as directions are concerned, there are only three possibilities: it came from below, from above, or from the sides. So far all are agreed. After an exhaustive discussion of all the possibilities, a guess is finally hazarded that it probably came from one of the three; but if not, then there can be no doubt whatever that it came from either one or both the other directions. However, on the basis of whatever hypothesis may have been selected, a diligent inquiry is next made as to the ultimate source of the minerals, what agent or agents it was that carried them from their primal resting place to the place where they were found, and why not somewhere else. Of course, this at once opens up a vast field of speculation, of possibilities or probabilities, but does not move us to firm and solid ground.

4. Well, I have turned over the last page of the discussion embodied under No. 3, expecting to find a scientific statement and summary of all that has gone before, but instead I find that I have reached the

index, and so I must close the volume. If I am a poor innocent, and new at the game, I probably entertain high hopes that, in view of all the minute and elaborate descriptions and arguments, I will finally be rewarded at the end with a body of positive, definite, and scientific statements that this ore deposit or class of ore deposits have certain well defined characteristics; that it occurs in certain other parts of the country or the world; that it will continue to a certain depth, will be of a certain width, and its metal content will be so much; and that exactly similar deposits will be found elsewhere when certain ascertainable surface conditions are found to exist; and not with the proviso that they may possibly be there, but with the short, convincing, clarifying little word that they *are*. Until the so-called 'Science of Ore Deposits' is able to deal in something a little stronger than mere guesses, or surmises, or might-have-beens, or may-have-beens, or could-have-beens; or so long as it is compelled to confine itself simply to statements of a multitude of mere observations which show nothing, which demonstrate nothing beyond them, it would be better to apply some other term than 'science' to the matter. Geology is the only 'science' which has been persistently and abundantly subsidized by the Government, and the only one which has continually been seeking it, and the only one which is still deficient in a groundwork of a positive and definite body of principles. If nearly a half-century of government, state, and even private subvention has failed to lay down a single solitary principle that can be called a guide to the every-day worker, what hope is there that the 'scientific research' and 'rigorous scientific investigations', that the Survey officials consider so essential, are going to add to the stock of useful knowledge? The hope certainly seems to be a forlorn and distant one.

ROYAL P. JARVIS.

Knoxville, Tennessee, May 14.

The Compensation Act and Prospecting

The Editor:

Sir I have been much interested in reading the different extracts from your letters on 'Prospecting,' as well as your editorial criticism on the 'Compensation Act.'

There is such a thing as 'strangling the goose that lays the golden egg.' The general principle and the object of the Act, no one will gainsay, but in its present condition it is a very serious matter, judging from your citation 'from an actual case.' Let us suppose a man was developing a prospect with two or three miners, thinking he might determine its merit in a month or two, he would hardly think of going to the trouble and expense of insurance, of temporary work of that class, and yet an accident might occur where one or all three of the miners would be killed. Suppose further, that the prospect had no merit, proved valueless, then where would the man 'get off,' for giving these few miners employment. It was not entirely a selfish

motive, he was favoring the miners to some extent, by giving them work, and a chance to draw wages. Why not fix a basal rate as is the case in other states? I am afraid if this is not adjusted, and that soon, you will not be able to boast long of California as the banner gold producing state. I do not believe that a \$3.69 ore (the average for the Mother Lode counties, as shown in late statistics) will stand this tax.

Now regarding the prospector. It is a well known fact that the old time prospector has nearly, if not quite, passed, but I believe in government aid to those remaining, and the new, to the extent of unrestricted access to the mineral territory of the United States, and I think that this condition exists, or is supposed to. However, I have met miners or prospectors who are averse to prospecting in forest reserves. This seems to be the stickler, especially when it is heavily timbered. The prospector says, "if I find anything I may lose it through the ignorance of some forest agent, who knows absolutely nothing of veins or ores." This in a measure is true and should be corrected. Even if it is not true, the idea prevails to some extent, and should be corrected, made plain and clear. I know that this is not the intent, but I also know of a case in point where a miner was subjected to no little trouble, expense, and delay in securing patent to his claim.

While on this forest reserve subject, I wish to cite a case where a man asked for a permit to cut his winter's wood, for domestic purposes. He waited for his particular trees to be marked until winter set in, when he was compelled to buy his wood from the owner of a patented claim, as his trees now were marked. This happened right in the midst of a big pine forest where, in my opinion, it would be better, and possibly good business, to pay for removing the dead and fallen timber, as a fire protection. It at least could be encouraged by removing the permit restrictions, if nothing more, on domestic wood.

Going back to the original subject, 'prospecting,' I am of the opinion that there is plenty of available capital for meritorious prospects, but capital must be given the consideration due and the prospector willing to assume his share of the chances. I believe these conditions are growing more and more favorable, and consequently the prospector and capital are getting closely together.

CLEARANCE K. COVIN.

Denver, Colorado, January 20.

Ore production of New Caledonia, a French island in the Pacific Ocean, in 1913 was as follows: nickel, 93,190 tons; chrome, 63,370 tons; and nickel mattes, 5893 tons, valued at \$1,500,000. The nickel ore exported to France averaged 6.27 per cent.

Feldspar output of the United States in 1913 was 118,932 tons worth \$771,501.

Aluminum consumption of the United States in 1913 was 72,379,090 pounds.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Of the timber cut in Colorado in 1911, approximately 25% was used by the mining industry of that state.

A mining exhibition is being held at Christiania, Norway, which shows the complete operation of a mine. All the important mining and reduction companies have contributed to the show, which remains open all the summer.

Products from the refining of 1000 gal. of petroleum at the Zorritos plant, in the province of Tumbes, northern Peru, are as follows: gasoline at 65°B., 130 gal.; kerosene at 46°B., 400 gal.; residue at 27°B., 400 gal.; and incondensable gas, 70 gallons.

Electric power is generally reliable, yet it sometimes fails. To insure a constant supply of power for vacuum pumps, used for the Belmont, Tonopah, slime-plant, in the event of the electric power failing, a 15-hp. steam turbine has been installed with good results.

The standard of silver, in the reign of Edward the Sixth of England, according to Roberts-Austin, reached the exceptionally low fineness of 250 parts per 1000. The restoration of the standard was completed in the reign of Queen Elizabeth and has not since been lowered.

Steel belts are being used in rolling mills in Germany, and cotton mills in Lancashire. They are a success and save a considerable amount of power. In one instance an 8-in. belt replaced ten 2-in. ropes; and in another, four 6-in. belts replaced twenty-two 2-in. ropes, transmitting 900 hp. in the latter case.

There are seven chemical abstract journals in Germany, three in France, two in England, and one in the United States (*Chemical Abstracts*), according to John J. Miller, in *The Journal of Industrial and Engineering Chemistry*. Six of these are abstracting from 110 to 633 journals each and publishing from 5200 to 25,971 abstracts per year, the larger figures being for the American journal, followed by *Chemiker-Zeitung* in Germany.

Cost of sand-filling stopes at the Witwatersrand Deep mine amounts to 15c. per ton of sand-filling. The surface cost, 7.6c., includes discharging the sand from the treatment vats, running and maintenance of conveyor belts, pumps, cones, and water lost at 15c. per 1000 gal. The underground costs include all timber, matting, launders, and labor required for putting in the stulls to retain the sand and for supervising the filling, according to E. E. Hardach.

Trypanosomiasis, generally known as sleeping sickness, is a dread disease found in the Congo, Uganda, and other parts of Africa. The malady originates in a spore, or *trypanosome* as it is technically termed, which is picked up by a species of fly, the tsetse fly, which is indigenous to Africa. In appearance, the insect who thus acts as a host, might be mistaken for the ordinary house-fly, although it is generally of slightly larger proportions. It frequents river areas or swamps, and emerges from its retreat in the early morning in search of food. The tsetse fly lives entirely on blood and attacks whatever animals are at hand, but exhibits a decided preference for the blood of human beings. It has a remarkable capacity for gorging itself with food and is capable of absorbing up to 200 times its own original weight. Investigations have shown that it feeds only every other day, and then only during daylight. In this respect it differs from the *anopheles*, or malarial mosquito, whose activities are confined to the night season. The sleeping sickness infection is thus carried by the fly to either animal or man, and some of the smaller wild animals are not immune from the fatal effects of the disease. In human beings the infection shows itself in glandular swellings in the neck. These are followed by a terrible and increasing lethargy, which eventually ends in death. No preventive or curative methods are known, but an immense amount of research work is being carried on in infected areas and in those schools of tropical medicine where cases of sleeping sickness are being watched. The only method of combating the disease is to quarantine entirely certain fly-infested districts against immigration. If this is not done, an appalling death rate is inevitable. According to Treves, the disease has been responsible for over 20,000 deaths within five years in one part of Uganda. Sleeping sickness has spread to northern and even southern Rhodesia, and travelers are now warned against the danger of entering certain districts. In an effort to stop the spread of the disease, large tracts of land have recently been thrown open, without restriction, for game shooting. The result has been that 'royal' game, and particularly the elephant, is being shot wholesale. In this way parts of Rhodesia are being rapidly denuded of valuable game which are not likely to spread the disease, whereas the smaller animals, such as deer and monkeys, which have been known to die of sleeping sickness, are left and possibly scattered by the hunters. On the Portuguese island of Principe, in the bight of Biafra, preventive measures against the spread of the disease are now being taken. Laborers are being sent to work with a strip of paper affixed to their backs. The paper is much the same as ordinary fly-paper, and is coated with an adhesive substance which imprisons the fly when it settles upon it. The number of tsetse flies thus caught are counted daily and then destroyed. It is hoped that a solution of this dread disease will eventually be reached.

Special Correspondence

NEW YORK

COLUMBIA UNIVERSITY ANNIVERSARY.—UTAH COPPER OUTPUT, LEACHING AND FLOTATION PROCESSES TO BE USED.—THE FLOTATION SITUATION.—CAMP BIRD PROFITS.—MESSINA MINE.—DEVELOPMENT AT SHEEP CREEK.—ORONOGO CIRCLE.

The event of the week has been the celebration of the fiftieth anniversary of the School of Mines at Columbia University, and as a result an unusual number of distinguished mining engineers have been in town, all of those who make New York their headquarters making it a point to be here for the exercises, while a considerable number have come from outside. Dr. F. Kolbeck, the rector of Freiberg, and T. A. Rickard, the delegate of the Royal School of Mines, were in attendance as representing their respective schools. Mr. Rickard made one of the addresses at the celebration. Hennen Jennings was also present, and among other distinguished engineers who were in New York during the week were Alfred James and C. W. Merrill.

The output of the Utah Copper mine has reached such a high level that the stock market prophets are looking forward to an increase in the dividend rate, which is 75c. per share per quarter. It is not likely to make very much change in the quotation if it comes, however, because movements of this sort are detected by the stock market operators a long while in advance, and are usually discounted in the quotations before the change is actually made. The Utah Copper is going ahead with its plans for the leaching plant, and hopes to have the first unit in operation within a year. So far as possible, the Company wishes to get enough of the plant in operation at an early date so that it may take all the oxidized material which is now being removed in stripping operations and thus save dumping it and afterward reclaiming it. The difficulty is, of course, that the technique of leaching operations is not yet thoroughly worked out, and consequently a small unit will be built at first in order to determine what is the best method of operating before the whole plant is constructed. Plans are well under way for the construction of a flotation plant to take care of the concentrate from the present Arthur and Magna mills. The fine concentrate from these mills is fairly high in silica, and consequently takes a smelting rate which is less profitable to the mining company. By putting this low-grade concentrate through a re-concentration, it has been the practice for several years past to raise its grade and thus command a better smelting rate for it. It is now the intention to use flotation instead of wet concentration for this second concentration. Just what effect the decision against the Minerals Separation company will have on the Utah Copper has not been announced, but it is quite possible that they will go ahead without making any arrangement with the Minerals Separation.

Another flotation enterprise which is making a good success is that of the National Copper Co., at Mullan, where J. M. Callow, of Salt Lake City, has developed a process which is giving excellent results. It is believed here that the process used at the First National cannot be regarded in any way as an infringement of the Minerals Separation patents, since the only agitation to which it is subjected is in Pachuca tanks, and the froth which is formed is quite different from the Minerals Separation froth, breaking up almost immediately after it has floated off the top of the tanks. Altogether, the flotation situation is a very interesting one, and it looks as though the Minerals Separation will not reap as large profits in America as it had at first hoped. Strong efforts are being made to appeal the Butte & Superior case to the Supreme Court of the United States, and it is possible that

this may be done, although the court has long made a practice of not hearing patent cases unless there is a very urgent need of doing so.

The Camp Bird mine continues to produce a good deal of ore, in spite of the fact that it was expected to be exhausted some little time ago. In the first quarter of this year 6700 tons of ore was mined at a profit of about \$100,000. Exploration work continues to disclose small quantities of ore. During the quarter the profits of the Camp Bird company from its holdings in the Santa Gertrudis amounted to approximately \$250,000. The mention of these companies draws attention to the fact that Arthur M. Grenfell, who is chairman of both companies, as well as of the Messina Development Co., has recently come to grief as a result of too extended operations in the railroad share market, and has lost his position as the dominant interest in these companies. It is generally reported that H. C. Hoover will acquire the controlling interests in the Messina company, and that being the case, it is to be expected that the Messina will be developed along more progressive lines than has been the case so far. Herbert Lang, in a recent issue of the *Mining and Scientific Press*, referred to the way in which metallurgical operations at the Messina have been conducted.

Now that the Sheep Creek adit of the Alaska Gold Mines has been completed, good progress is being made in the various levels in getting the mine ready to furnish a large tonnage of ore upon the completion of the mill. No. 8 and 9 levels west are both connected with the surface and finished. No. 7 will be opened to the surface in about six weeks. Developments incidental to the preparation of the Sheep Creek adit for the handling of the ore are particularly interesting. It will be recalled that the connection from the bottom of the shaft, which at this level is several hundred feet in the foot-wall, to the adit, had passed through a formation containing gold, the last 20 ft. yielding high assays. At several points in the adit, stations are being cut for the ore-chutes and the adit is being widened to permit the laying of loops. At both No. 1 and No. 2 ore-ways the cutting of the station for the chutes is practically finished, and a drift west, wide enough for passing track is being continued. All the rock taken out in this development is ore, and this foot-wall orebody as opened is looking well. This, of course, is of importance as confirming the indications given in the driving of the connection mentioned above. Development is progressing at the rate of 700 ft. per week. At the dam, pouring of concrete was resumed on April 24. This work is progressing smoothly; two shifts are working on this and averaging 600 to 700 yd. per 24 hours. Pouring of the concrete should be completed not later than the middle of July. The railroad is now connected clear through to the Sheep Creek portal camp, and it is possible to send materials and supplies directly up to the mine through this. Progress at the mill is particularly satisfactory. At the coarse-crushing plant the steel workers are now at work riveting, and by the time they are through with that, which will be in about two weeks, all the necessary steel will have arrived for the main fine-crushing plant, so that they can begin at once on the erection of the roll and concentrating unit. The steel itself has been arriving on schedule time in good shape. Pouring of the concrete for the roll plant is going ahead night and day at the rate of about 300 yd. per day. This should be completed by the time the workers are ready to start erection of this plant.

The Oronogo Circle mine, the largest zinc and lead producer in the Missouri-Kansas-Oklahoma district, has been sold to Turner & Co., of New York City, by Henry Russell Platt and J. B. Moos, of Chicago, the former owners. The Oronogo Circle company was capitalized at \$300,000, and it is understood the purchase price was slightly in excess of this figure. A. J. Burnham, manager of the mine for several years, will be retained in this capacity. The mine consists of 126 acres

of the Granby Mining & Smelting Co. land at Oronogo, Missouri. The Company holds a first lease which will expire in 1926, and a royalty of 10% of the gross sales of ore is paid to the land-owners. Ore has been mined down to a depth of 240 ft., at which level mining is conducted on a large scale. Core-drilling shows the orebody almost continuous down to 300 ft.; below this level there is some thin ground,

varying from 1 ft. to almost 6 ft. wide. This 'vertical' has been followed for a distance of nearly 300 ft., and of the ore extracted 50 tons was shipped to the Golden Reward cyanide plant, at Deadwood, which assayed from \$16 to \$20 per ton, and on which the net results amounted to \$370. Other ore, classed as milling grade, to the amount of several hundred tons, remains on the dump, and 50 tons of shipping ore will

SURFACE EQUIPMENT, ORONOGO CIRCLE MINE, WEBB CITY, MISSOURI.

and then, at greater depth, other orebodies are found. A large quantity of ore is ready for stoping. A gasoline locomotive hauls the ore from the outlying shafts to the mill, which has a capacity of 1000 tons per 10-hour shift.

DEADWOOD, SOUTH DAKOTA

DEADWOOD STANDARD, HEIDELBERG GROUP, ORO HONDO, AND DAKOTA CONTINENTAL MINES DEVELOPMENT.—IMPROVEMENTS TO GOLDEN REWARD MILL.—WASP No. 2.

The Deadwood Standard property, in the Ragged Top district, has been leased by Hodges, Burkett & Nicholls, of Terry, who intend to thoroughly prospect the ground during the coming summer. It is equipped with a dry crushing, direct leaching cyanide mill of 150-ton daily capacity, which is being operated at part capacity at the present time. Except for a few months' work a couple of years ago, the property has been idle for twelve years, and the mill is not in as good repair as it might be; however, if the summer's run is successful it is proposed to put on a new roof and make other necessary repairs before winter comes. The lessees have opened some new orebodies, and claim to be getting satisfactory results.

Since last August, when development started on the Heidelberg group, on Two Bit creek, \$5000 has been expended by the local people who became interested through the promotion of the enterprise by the Deadwood Business Club. The final installment on the subscriptions to the fund was payable May 23. Since developments have been highly satisfactory, plans for raising further funds are being considered; and at a recent meeting of the owners it was decided to incorporate a company, and from the proceeds of the sale of stock carry on mining work. It will be remembered that in return for the \$5000 which was pledged last summer the subscribers were given a half interest in the property; the money was to be expended in developing the ground under the supervision of a board of trustees consisting of the two original owners, two men selected by the subscribers and a fifth man to be selected by these four. Work at the mine has demonstrated a 'vertical' of ore in the Cambrian shales

be forwarded immediately. It is believed that the basal quartzite is several hundred feet below the present workings, and it is proposed to sink a working shaft to this quartzite and open the 'vertical' on that horizon. Preliminary to shaft sinking, a diamond-drill hole was put down to determine the position of the quartzite, the character of intervening formation, etc.; the facts thus gathered to serve as a guide in sinking, purchase of machinery, and equipment. The proposition is particularly interesting. The mine is in an entirely new district, and several miles from any producing mine. It is a pioneer in a new territory, directly tributary to Deadwood. The formation is almost identical with that of the Bald mountain and Ruby Basin districts, which have been large producers. The ore is amenable to cyanidation. Tub tests at the Golden Reward mill show extraction, on 20-mesh, unclassified material, of 91 to 93%. The property includes 180 acres, part of which is heavily timbered and supplied with water for large cyaniding operations; at least two excellent sites are available for milling plant. It is three miles directly east of Deadwood, but five miles by a good wagon-road.

Operations at the Oro Hondo came to a standstill when it was discovered, after removing the water, that the boiler capacity was not sufficient to operate the hoisting engine, air-compressor, and the necessary pumps which would be used in sinking below the 1050-ft. point, the present bottom. To remedy this, two new boilers are being installed, and when in shape for use, sinking will be started with a full crew of three shifts. It is proposed to continue the shaft to the 2500-ft. level, and do it in the quickest practicable manner. John T. Milliken, president of the Golden Cycle company, of Cripple Creek, is personally furnishing the funds for this work. The property adjoins the Homestake holdings on the south and east, the shaft being situated 2640 ft. from the Ellison shaft of the Homestake. It is believed that the Homestake orebodies traverse the property, and will be found by sinking.

The Golden Reward company will spend \$15,000 in improvements and repairs to its mill at Deadwood. The most important piece of work contemplated is the installation of a tube-mill, work on which is well in hand. Several minor changes in the interior arrangement are to be made, and the mill brought up to date.

At the Dakota Continental copper property, near, Hill City, sinking has been suspended and cross-cutting is now in progress on the 850-ft. or lowest level.

Since resuming work at the first of the year, the Wasp No. 2 has been operating successfully and a good surplus is accumulating, so that the shareholders anticipate a dividend at an early date. The property is now in charge of Edward Manion, who is pushing its capacity to the limit.

JOHANNESBURG, TRANSVAAL

EAST RAND PROPRIETARY MINES RESULTS FOR 1913, AND THE FUTURE.—MARCH OUTPUT AND PROFITS.—PROPOSAL TO AMALGAMATE ALL THE RAND PROPERTIES.

The annual meeting of the East Rand Proprietary Mines was this year but little different from other Company meetings on the Rand, notwithstanding the fact that this huge mining undertaking is just on the point of entering a serious crisis in its career. The year's profit, after allowing for debenture interest and special expenditure, was £831,565, but there are signs that the current year's profit will be lower. Owing to various drawbacks, development has fallen behind somewhat, and advantage is to be taken of this fact by closing down the Driefontein mill, in the expectation of reducing costs of ore reduction by milling the same tonnage with the three as was formerly milled by the four plants, and at the same time making room for further additions, providing that future developments justify such a step. It is just this question that adds interest to the present position of the Company. During the last year the profitable ore reserves have been depleted to the extent of 400,000 tons, leaving at the end of the year 5,600,000 tons of profitable ore against 6,000,000 tons at the close of the previous year. This means that there is only about three years' supply of such ore blocked out. It must not be overlooked that it will not prove an easy task to increase the ore reserves, as where good ore is likely to be found, large quantities of water are likely to be encountered, and to pump water from depths varying from 2000 to 4000 ft. is not an easy task. On the other hand, where development is easy the ore is poorer, and, as far as can be seen at present, the East Rand Proprietary Mines is not by any means clear of its troubles. It is the uncertain value of the large area to the dip of the Hercules and Angelo Deep shafts that somewhat obscures the future prospects of this extensive property. More confidence is felt that the areas to the west, and beyond the water dike, will contain better ore than the ultra-deep areas east of the dike, to the south of the Angelo Deep and Hercules shafts. It is intended, however, to attack these areas in an energetic manner during the current year, and results will be awaited with more than ordinary interest. As far as development has gone during the year, results are considered satisfactory, but it must not be forgotten that all work in these doubtful areas has been avoided as much as possible. It is interesting to notice that the compensation and insurance against miner's phthisis has cost this Company during the year about 10c. per ton milled, with an even heavier additional cost likely to be added in the immediate future. The working results for the year may be briefly described as 1,769,000 tons milled, yielding 646,185 oz. of fine gold valued at £2,718,484, or an average recovery of \$7.38 per ton; while the working cost has averaged \$4.76 per ton, leaving a working profit of £965,277 or \$2.62 per ton milled. How long the Company will be able to maintain these results will, of course, depend upon the success of future developments. Asked to state the estimated life of the property, the chairman of directors replied that it was impossible to give exact figures, but the directors were of the opinion that profitable mining in the property will not cease during the next twenty years.

The gold output for March shows a more assuring tend-

ency than for several months past, the total value, according to the Chamber of Mines, being, for the whole of the Transvaal, £2,917,346. As for the total output for the present year, it seems doubtful whether it will reach that of 1913, which, it must be remembered, showed a marked decrease when compared with that of 1912. One important feature of the March output declaration was the reappearance of the Randfontein Mines at the head of the list of producers with a yield valued at £246,589, as against £241,700 for the Crown Mines, the East Rand Proprietary Mines making rather a bad third with £210,131. The Ferreira Deep, which produced £111,609, seems to have taken indefinitely the position so long occupied by the Robinson mine, at one time the richest mine on the Rand. The total profits earned by the different groups in March was declared at £929,299. The only feature of encouragement to be found in the Rand gold-mining industry today is the increase in the native labor supply, March showing an improvement of 5142 as compared with February, but even then it is 44,918 below that of a year ago.

The all-absorbing mining topic on the Rand recently has been the evidence placed before the Dominion's Commission with regard to the benefits, or otherwise, of merging all the gold mines on the Rand under one control. It may be a day-dream, but there can be no doubt as to the opposition such a proposal would, if seriously entertained, receive at the hands of public opinion on the Rand. It has been pointed out in some quarters the ease with which the Rand Mines, Limited, as its name implies, could become the parent company of the whole of the gold mines of the Rand. Raymond Schumacher, a director of this concern, did not hesitate to express the opinion that while in some respects such an amalgamation might be of benefit, the objections likely to be raised against it would render its adoption inexpedient and impracticable at the present time; in fact, the Eckstein group, of which he was the representative, must not be regarded as in favor of the proposal. Apart from anything Mr. Schumacher said, it must not be forgotten that under existing conditions the Rand Mines and Central Mines already possess and control most of the properties worth anything on the Witwatersrand, including the pick of the mines. That may or may not be one of the principal reasons why this fortunate group may not regard the proposal with favor. Undoubtedly, the scheme would enable the best use to be made of the somewhat precarious and unskilled native labor supply, but at the same time it would bring mining on the Rand to an earlier end, unless, as prophesied, working costs would as a result of the scheme be materially reduced. It cannot be said that the different mine amalgamations carried out on the Rand have brought about the anticipated reduction in working costs, or increase in working profits, and it is on this account difficult to see that the widest extension of the scheme would be attended, on the whole, with any better results. The Kimberley instance of amalgamating the whole of the area over a diamond 'pipe' is not one analogous with the scheme of amalgamation of the Rand, where the first result would be the adoption of selective mining on an extensive scale, leaving the less profitable areas to be worked later, when it is problematical whether they would be worked to greater advantage.

No doubt the Consolidated Gold Fields of South Africa might be pleased to get rid of the troublesome Germiston low-grade and unprofitable area, as might also the Goerz group of its Western Rand areas; but it is doubtful whether these areas would be worked at all under this wholesale amalgamation scheme, and, even if they were worked, it is hard to see that they would be handled any better than they are today. With the calling into existence of such a general amalgamation scheme, a general reduction of unskilled and skilled wages would eventually follow, and possibly earlier than under existing conditions; but after all, the Rand con-

raies only a fixed amount of gold, and it will only be mined so long as conditions enable it to be extracted at a profit, to which all other matters become subordinate.

MELBOURNE, AUSTRALIA

GREAT COBAR'S TROUBLES.—GREAT FITZROY.—BROKEN HILL JUNCTION.—TASMANIA COPPER AND REFRACTORY ORES OF THE WEST COAST OF THE ISLAND.

The mining industry in the eastern states cannot be said to be in a very flourishing condition. The announcement regarding the shutting down of the Tasmania gold mine, the closing of the Chillagoe smelters, and the troubles in connection with Mt. Elliott, the Great Fitzroy, and Broken Hill Junction have been followed by the temporary total cessation of work in the Great Cobar. Bewick, Moreing & Co. have recommended this step, and the firm's general manager in Australia, G. C. Klug, has announced that in his opinion profits will in the future be much less than had been anticipated. The recommendation includes the expenditure of \$175,000 and has put an end to a reconstruction scheme which had been adopted by the debenture-holders' committee. The face value of the shares is \$25, and the market price has fallen to 75 cents.

As for the other concerns mentioned above, the Great Fitzroy has given the Mount Morgan company a three months' option of purchase on the Laloki mine, Papua, island of New Guinea, the purchase price being fixed at \$375,000. Part of this sum, if it ever changes hands, will be used for the redemption of the existing debenture debt of \$180,000, and the balance will go to development work. The arrangement provides for the Great Fitzroy having a call on 25% of the Laloki output for use in its smelters at a price 10% above cost. If the deal comes off it will greatly improve the Great Fitzroy's position; but still it constitutes a serious admission of financial impotence.

The Broken Hill Junction mine and plant were recently offered for sale at auction, but no satisfactory offer was forthcoming. It was then proposed to reconstruct the Company on a basis which would give the Company about \$75,000 with which to put things straight. To the general surprise, the invitation to underwrite the new shares to be issued was so well responded to in Sydney, Melbourne, and Adelaide, that applications exceeded the supply of shares by 20,000. This was probably the outcome of recent satisfactory developments at Broken Hill, especially in regard to treatment methods, for there is nothing in the mine concerned to justify the confidence shown in its future.

As a result of an inspection of the Tasmanian Copper Co.'s property at Rosbery by G. C. Klug, of Bewick, Moreing & Co., and A. Rutter Clark, a circular has been issued by the directors stating that notice has been given to the Metals Extraction Co. on the cancellation of the contract existing between them, and that a six months' option has been accorded to a syndicate which is not named. The secretary of the Metals Extraction Co. questions the power of the directors of the Tasmanian Copper Co. to give the option while the present contract is in existence, so there is a possibility of trouble.

The west coast of Tasmania is a mining district that is being brought into considerable prominence at the present time because of the attention which has been drawn to its huge deposits of refractory zinc-lead sulphide ores, ranking among the largest in Australia, according to a writer in the *Australian Mining Standard*. The composition of these ores is fairly persistent, and would average about as follows: gold, 0.16 oz.; silver, 8 to 12 oz.; lead, 8 to 10%; zinc, 26 to 26%; copper, 8 to 10%; iron, 12 to 15%; manganese, 1.5%; alumina, 2%; sulphur, 28 to 32 per cent.

The chief minerals are pyrite, zincblende, and galena, and these are generally so finely and intimately intermixed that a

clean mechanical separation becomes a matter of absolute impossibility, except when very fine sliming is resorted to. Apart from a company working a wet process, the only company which has seriously grappled with the problem has been the Tasmania Smelting Co., Ltd., an English concern, which owns large and fairly well equipped works at Zeehan, about 20 miles distant by rail from the mines of the Mount Read-Rosebery district, reached by and connected with two lines of railway. From a metallurgical point of view, its operations have been successful, and but for the somewhat limited and variable output of the mines, the business, it is said, would have been successful commercially. Over 250,000 tons of this refractory ore was treated here, and a clean silver-lead bullion and a ferruginous and highly zinciferous slag produced. Foreign metallurgists have praised the work of this plant on such ore. Altogether the Zeehan smelters have treated 441,911 tons of crude ore, exclusive of almost an equal quantity of iron gossan from the Dundas field, since the erection of the works in 1898. During the years 1898 to 1913, the total output of crude ores of the Zeehan field, including the Mount Read district, was 513,096 tons.

In 1899, the smelting company treated only 15,346 tons of crude ore against 11,460 tons exported to Europe; while in 1912, the last full year of the Company's operations, it treated nearly 50,000, against an export of 1900 tons, this showing the practical value of the smelter to the district. Government records show that of recent years the ore bought by the smelter averaged 10% lead and 13 oz. silver per ton.

CALGARY, ALBERTA

OIL BOOM CONTINUES TO GROW.—HIGH-GRADE OIL FLOWING.—SPECULATION IN OIL SHARES.

Calgary has at last had a genuine oil discovery, which has resulted in great excitement among westerners, followed by tremendous speculation and wild-catting. The find occurred on May 14 at the Dingman oil well near Okotoks, and 36 miles south of Calgary, belonging to the Calgary Petroleum Products Co. Shares of this concern jumped at once from \$12.50 to \$200 and over. All the recently organized companies were kept busy taking subscriptions, and new companies were formed whose shares found ready purchasers. The Calgary Industrial Bureau made a statement that the well produced 150 to 200 bbl. per 24 hours. The oil is high grade. In addition to the oil, the natural gas output is estimated at 2,000,000 cu. ft., the gas being wet and containing 1 to 1.5 gal. of gasoline per 1000 ft., said to be capable of being extracted at a profit. The genuine character of the find is further confirmed by a statement from J. S. Dennis, assistant to Sir T. G. Shaughnessy president of the Canadian Pacific railway, which is greatly interested in the discovery, as it owns large areas of western lands. Mr. Dennis states that there is no doubt that a find has been made, there being 2000 ft. of oil in the 10-in. hole at the Dingman well at the last measurement made by the department officials. The sudden impetus given to reckless speculation, and the sale of wild-cat stocks is likely to result in widespread loss to the public if it is permitted to go on unchecked. The province of Manitoba, however, has taken prompt action for the protection of its citizens. Recent laws have given wide powers to Judge Robson, public utilities commissioner, to regulate the sale of stock. A number of Calgary brokers who came to Winnipeg to sell shares in oil companies, were refused permission to do so until they had satisfied the commission of the genuine character of their propositions. He requires to be assured that the company has a bona fide well, and that the stock is not speculative, and a financial statement must be furnished showing that the company is on a sound basis. When satisfactory proofs to this effect are forthcoming the promoters can obtain a certificate authorizing the sale of stock, which is otherwise illegal.

General Mining News

ALASKA

The report of the mine inspector, Sumner S. Smith, for the territory of Alaska to the Secretary of the Interior, for the fiscal year ended June 30, 1913, has just been published at Washington, D. C. The inspector's headquarters is at Juneau, but the office is short of funds for clerks, furniture, instruments, and laboratory work. Trips of inspection were made through the Fairbanks and Nome placer-mining districts, the coalfield of Controller bay, and the lode mines of southeastern Alaska, Kenai peninsula, and the Willow Creek part of the Susitna district. The Bering River coalfield was discussed with members of the U. S. Bureau of Mines and mine inspectors of Colorado and Idaho. Over 40 dredges have been placed on the Seward Peninsula to date, one being for stream tin. Boats were worked in the Circle, Fairbanks, and Iditarod districts. Lode mining at Fairbanks received a good impetus. New copper mines on Prince William sound started shipping ore. At Juneau two companies are developing the low-grade orebodies of Silver Bow basin. A small though steady output of gypsum and marble was made from southeastern Alaska. There was an ample supply of labor for all districts, and about 1500 new employees started in the Juneau district. Wages in the interior of the territory are relatively low considering the cost of living, board at \$2.25 per day, and the high transport charges. The 8-hour law for metalliferous mining went into effect on July 24, 1913. Recommendations are given for the betterment of mining conditions.

CHISANA

United States mail has been sent in limited quantities to Chisana during the winter, and a new contract has been let

THAWING GRAVEL. MANLEY AND PRICE BOILER ON THEIR LAY ON JAMES' GROUND 4 ABOVE, CHISANA.

to J. A. Fagenberg to carry 200 lb. each two weeks from McCarthy. The postmaster at Chisana, T. Kettleson, has written to H. T. Ray at Fairbanks stating that there is little activity in the new district, and men are leaving for other

fields. It was hoped that the Manley-Price-Ives outfit would prove considerable ground, but they have given an option to H. Hamshaw, of the Shushanna Gold Fields Trading & Mining Co., which concern is not regarded seriously at Chisana.

ARIZONA

COCHISE COUNTY

(Special Correspondence.)—Prospecting at the Great Western copper claims has been stopped, and the owners, Young Bros., are to start work at the old Mammoth gold mine, on the San Pedro river, in Pinal county. The mine has been opened to 700 ft. Tailing from the old mill has been concentrated for its vanadium content, and also cyanided twice. The vein is said to be of considerable extent and has produced some fine specimens of crystalline vanadium.

Courtland, May 28.

GILA COUNTY

(Special Correspondence.)—Concreting the Inspiration main shafts is being done at the rate of 5 ft. each per day. No forms will be moved until the two shafts are completed. The timber used for concreting can then be used for underground work. The test mill is treating 1000 tons of ore per day. A 66-in. Bradley crusher is installed. Improvements are being tried in the 8 and 12-compartment flotation machines.

Forty men are employed at the Warrior mine, and 50 tons of ore per day is sent to El Paso. During May the Iron Cap produced 16 cars of ore, the last six assaying 8.77, 11.57, 15.09, 8.72, 6.69, and 8.69% copper. The 800-ft. level is opening well. From the Superior & Boston 100 tons of ore per day is shipped to El Paso. Lessees are also producing ore. Development in the Arizona Commercial continues satisfactory.

Miami, May 30.

GREENLEE COUNTY

The Detroit Copper Co. is reopening old ground which was abandoned about 30 years ago. The shaft being overhauled is the Old South of the Blue mine, which is under the town of Morenci.

MOHAVE COUNTY

A first payment, \$10,000, has been made for the purchase of the Copper Giant mine by the United Verde interests. The balance of \$20,000 will be paid in four months. A large orebody has been opened at 450 ft. The ore will be sorted at the mine and shipped to the smelter at Clarkdale.

YAVAPAI COUNTY

(Special Correspondence.)—Tests on tailing at the old Congress mine show that a high recovery is possible. A large-scale plant is being arranged, using old tanks below the dump, and if this plant checks laboratory experiments, a big one will be erected. The tailing is from the 40-stamp mill which worked about 30 years ago.

Congress, May 28.

CALIFORNIA

ELDORADO COUNTY

The new mill at the Ingraham mine started work on May 1. J. G. Harrell, of Sacramento, is in charge. Four old mines in this county are being reopened, namely, the Hairlah and Montezuma near Nashville, Crusader, Church, and Union near Eldorado.

NEVADA COUNTY

The North Star Mines Co. has paid its first quarterly dividend for 1914, amounting to \$50,000. Preliminary work has started at the Murchie mine.

INYO COUNTY

The Wilshire Bishop Creek mine equipment has been examined by Luke Severy, who will be followed by Harry Johnson, of Los Angeles, in inspecting the mine, when it is unwatered. Snow has disappeared from the camp, and it is hoped that the mill will be producing gold in three months.

HUMBOLDT COUNTY

Oscar H. Hershey, of the firm of Burch, Caetani & Hershey, of San Francisco, arrived at Eureka on May 22 to make an examination of a copper property on Horse mountain owned by Messrs. Loofbourrow and Perrott, H. W. Jackson, L. Everding, and others, who form a close corporation of 15 members. This ore deposit is a peculiar one, and a good deal of money has been spent in this and Del Norte county in development without any return up to the present. On Horse mountain, after considerable work, there is nothing in sight but the "float" ore and a few disconnected pockets of copper ore underground in serpentine rock. This deposit has been referred to by the *Mining and Scientific Press*. For several months ore from the Horse Mountain mine has been on view on Bush street, San Francisco.

MARIPOSA COUNTY

(Special Correspondence.)—Some good ore has been opened on a claim near the Pine Tree mine by Howert and Medrano. Machinery on the Santa Rosa mine has been sold for installation on Shroder brothers' claim, near Mariposa. The Number Five mine is said to be under option to Eastern people. L. C. Worthington, of Bakersfield, and associates are reopening some quartz claims in Devil's gulch. The Number One mine, near Hornitos, is said to be a good property but is closed down for no important reason. A 5-stamp mill has recently been started at the Malone mine, on Bear creek, with W. H. Johnson in charge. David B. Scott, of the Miami Copper Co., Arizona, is visiting a mine six miles northwest of Mariposa. After an absence of 60 years, W. H. Westfall, who came to this county in 1850, has returned to permanently live in Mariposa.

Mariposa, May 29.

RIVERSIDE COUNTY

Development of the iron-ore deposits of the Eagle mountains now only awaits clear titles to the claims of the Iron Chief Mining Co. Eighty claims have been declared valid, and this decision is to go to the General Land Office and the Secretary of the Interior for review.

SAN DIEGO COUNTY

(Special Correspondence.)—The North Hubbard gold mine, in the Julian district, is to be reopened by San Diego people. It was worked for free gold only some years ago. A mill will be erected.

San Diego, May 29.

SHASTA COUNTY

After lying dormant for about 200 years, Lassen peak, 10,437 ft. high, in the southeast corner of this county, started throwing out some mud, steam, and rocks on May 30. There has been a good deal of thermal activity in the district for many years. The new volcanic action is causing considerable interest among geologists. It is probably geyser action.

SISKIYOU COUNTY

From the Quartz Hill mine, at Scott Bar, nuggets and fine gold worth \$3,000 was recovered one day last week. Nunan Bros. own the property, and they have produced from \$10,000 to \$12,000 per year with a few men. At the St. Albans copper-gold mine in the Blue Ledge district, the Company proposes to erect a concentrating plant to cost \$25,000. A large tonnage of ore has been opened. The Trail Creek Mining Co. has started its stamp-mill.

SOLANO COUNTY

The St. John quicksilver mine, northeast of Vallejo, which has been idle for a considerable time, is to be reopened under the management of Clifford G. Dennis. New plant to treat 1000 tons of ore per month is to be installed.

TRINITY COUNTY

Work has been resumed at the Nash gravel mine, on Coffee creek. This property has produced a good deal of gold.

COLORADO

The geology of the pitchblende ores of Colorado is described by Edson S. Bastin in professional paper 90-A of the U. S. Geological Survey. The field studies of the mode of occurrence at Quartz Hill, Gilpin county, were made late in 1912. Of the output of uranium ores of the United States, nearly all came from sandstones of the high plateau regions of southwestern Colorado and southeastern Utah, in which the ores occur as the canary-yellow mineral carnotite ($2\text{UO}_3 \cdot \text{V}_2\text{O}_5 \cdot \text{K}_2\text{O} \cdot x\text{H}_2\text{O}$). This mineral occurs in granite pegmatites in North Carolina; and in intimate association with metallic sulphides in certain mineral veins in Gilpin county, Colorado. Pitchblende has been obtained from the Calhoun, Wood, Kirk, German, Belcher, and Alps mines at Quartz Hill. (The occurrences in Europe and England are described.) The veins of these mines are of two types, pyritic and lead-zinc, and have been worked principally for their precious-metal content as well as some copper and lead. The principal primary minerals of the first type are pyrite and quartz, with some chalcopryrite, tetrahedrite, enargite, fluorite, and rhodochrosite in smaller amounts. In the other type the primary minerals are galena, sphalerite, pyrite, chalcopryrite, quartz, and calcite. The pitchblende ores of Quartz Hill are believed to represent merely a local and unusual variation in the main sulphide mineralization of this region. No evidence was found to support Forbes Rickard's theories as published in the *Mining and Scientific Press* of June 7, 1913. Nickel and cobalt have not been found at Quartz Hill. The Quartz Hill uranium ore belt was examined during May by R. D. George, state geologist. This was done at the instance of Du Pont interests. The Zimmerman group of claims, including the White, Effie, Ezra, Blagdon, Telephone, Telegraph, and Bouvier, surround the Du Pont claims. Mr. George stated that greater orebodies with higher mineral content should be found at lower points, instead of near the surface. The Bezzant mine, in Leavenworth gulch, is a promising one for uranium ores.

CLEAR CREEK COUNTY

(Special Correspondence.)—The failure of Gay & Sturgis, of Boston, has brought to an end their connection with the reopening of the Terrible-Dunderberg, under the management of A. J. Eveland. A. L. Wells, who first took up this old property, which had been closed and full of water for several years, will continue development work, which is now under the direction of Arthur Canahan. The Terrible and Dunderberg properties, which adjoin the Seven-thirty and Dives-Pelican, were once producers of lead ore rich in silver, and it was hoped that new ore reserves might be developed by exploration along the Terrible vein on the bottom levels, and also that modern milling methods would render profitable some of the low-grade ore which had been used as filling or left in the slopes in the earlier work. The rejuvenation of this old property would do much for the Georgetown district, and it is to be hoped that the work will be successful. Georgetown, May 25.

CUSTER COUNTY

Some cerussite (carbonate of lead) deposits of this county are described by J. Fred Hunter in *Bulletin* 580-C of the U. S. Geological Survey. The deposits near Ilse were examined in June 1913. The Terrible mine is the most important in the zone. S. F. Emmons visited the area in 1887. Oak creek, along which the ore occurs, is 8100 to 8400 ft. above sea-level. The country in the vicinity of the cerussite belt is chiefly granite, intruded by dikes of syenite, diorite, and pyroxenite. The ore mined from the Terrible is said to have averaged 5 to 8% lead, and could be concentrated to 60 or 70 per cent.

PITKIN COUNTY

The Smuggler Mining & Leasing Co., of Aspen, is pumping 2000 gal. of water per minute and mining 400 tons of ore per day from the Free Silver shaft. This ore is concentrated

at the Company's mill, and the product sent to Colorado smelters. Of great interest to Aspen people is the Hope adit, being driven in the Little Annie claims. It is in 3800 ft., and has from 500 to 700 ft. to go to cut the vein.

TELLER COUNTY (CRIPPLE CREEK)

About 1200 ft. of track has to be laid to reach the face of the Roosevelt tunnel, which should be finished in 30 days. The size of the extension is to be 7 by 8 ft. in the clear, with a ditch 30 by 42 in. on 0.33% grade. The ventilating plant is in operation clearing out foul air. Allen L. Burris, of the El Paso Consolidated company, states that the 1170-ft. drifts have not been driven far enough to cut the rich ore mined on levels above. At 1350 ft. depth, ore worth from \$12 to \$35 per ton has been proved for 120 ft. over two to six feet.

IDAHO

CUSTER COUNTY

As soon as the smelter at Mackay has been overhauled, it will be started again by the Hill Copper Co., in charge of J. H. Greene. A good tonnage of ore is said to be blocked out.

SHOSHONE COUNTY

At the Ray-Jefferson mine, No. 2 adit is being driven 450 ft. below No. 1, and should cut the vein at 800 ft. This property is in the Sunset district, where are also the Amazon-Manhattan, Tuscumbia, Idora Hill, and others. On June 4 the Bunker Hill & Sullivan company paid dividend No. 201, amounting to \$81,750. The total to date is \$15,219,750. Additions to the Hecla mill are expected to increase the capacity by 40%, or a total of 350 tons per day. In No. 5 adit of the Hunter mine, 18 in. of gray copper ore, containing from 253 to 900 oz. silver, has been opened. The National mill is to be shut down, as the copper mine is not able to supply it with ore to full capacity.

MICHIGAN

HOUGHTON COUNTY

During the first four months of 1914, the Mohawk mine has produced 127,348 tons of 'rock' yielding 2,454,300 lb. of 70% copper 'mineral.' The present daily output of 'rock' is 2250 tons, which is to be increased to 2600 tons in June. The Isle Royale has produced 106,230 tons of 'rock' during the four months, yielding 1,611,513 lb. of refined copper. Daily shipments are now about 1750 tons. Costs at both mines are decreasing each month.

NEVADA

ESMERALDA COUNTY

During April the Goldfield Consolidated mill treated 28,221 tons of ore, yielding a net realization of \$150,764. Development in the mine totaled 2409 ft., costing \$7.39 per foot. Costs for the month were \$6.05 per ton, including 18c. for examining the Aurora mine in Mineral county. Six lessees were working in the Goldfield mine, two producing ore worth \$4214.

The Goldfield Consolidated Mines Co.'s output in May was \$327,000 from 30,200 tons of ore. Operating expenses were \$175,000, and profit \$152,000.

HUMBOLDT COUNTY

(Special Correspondence.)—The Nevada Packard Mines Co. has received settlement for a 25-ton car of ore from the Kromer-Hampton-Loufek lease at Rochester. The car contained 50,451 dry tons and was settled for on the basis of 0.03 oz. gold and 129.40 oz. silver, a total value of \$74.68 per ton. After deducting 5% for loss in smelting, the value of the shipment was \$1790. The lease is employing four men, who are said to be taking out about 30 tons per month of this grade of ore.

Rochester, May 28.

LYON COUNTY

The usual ore shipments are being made from the Nevada-Douglas property. A large tonnage of 3% copper ore is being opened in the Casting Copper mine. Between 600 and 700 ft. in the Ludwig, 8 to 9% ore has been cut.

NYE COUNTY

Machinery is arriving for the White Caps company at Manhattan. The 75-hp. hoist, from the Denver Engineering Co., is the largest in the district. A new Leyner compressor has been purchased. Ore worth \$25 per ton has been opened at 200 ft. in the Big Pine. Development at the Wall-Blaker claims has been stopped by the bondholders. Victor Barnt, of the Railroad Valley Co., is to reopen the old silver mine at Barcelona, 10 miles north of Manhattan.

NEW MEXICO

SOCORRO COUNTY

(Special Correspondence.)—Rich bornite has been opened in an upper stope of the Deadwood mine. Denver people have secured a bond and lease on the Gold Eagle claims, north from the central portion of this district. Shipments of ore will be made from a 30-in. vein. Work on the Eberle mine, by the Oaks Co., is proving satisfactory. Good ore has been sent to a local mill. A large vein of \$25 ore has been opened at 400 ft. in the Pacific. The best ore mined in the district comes from stopes above this level. The output to date is \$150,000. On May 18 the Socorro Mining & Milling Co. took over the Pacific, on which an option is held.

MAP OF NEW MEXICO.

An aerial tramway is to be erected between the mine and the Socorro mill by September or October, also a water and power line.

Mogollon, May 25.

OREGON

The mineral resources of southwestern Oregon are described by J. S. Diller in *Bulletin 546* of the U. S. Geological Survey. This publication of 147 pages is accompanied by illustrations and interesting maps of the various districts, and covers the geology, mineral production (\$6,218,741 since 1900), gold-quartz lode mines, copper mines, and prospects (blister copper output in 1912, 260,429 lb.), placer mines, and coal.

BAKER COUNTY

The Gold Center placer ground, west of Summer, has been

leased by J. B. Wetherell to the Hudson Placer Mining & Dredging Co. of Portland, on a royalty basis. The Company will install a steam-shovel and 'land' dredge of a capacity of 100 yards per hour.

UTAH

The mine production of gold, silver, copper, lead, and zinc in Utah, in 1913, by counties, was as follows, according to Victor C. Heikes, of the U. S. Geological Survey:

| County. | Number of pro-ducers. | Ore treated, short tons. | *Gold, fine oz. | *Silver, fine oz. | Copper, pounds. | Lead, pounds. | Zinc, pounds. | Total value. |
|-----------------------|-----------------------|--------------------------|-----------------|-------------------|--------------------|--------------------|-------------------|---------------------|
| Beaver | 24 | 168,158 | 1,118 | 344,437 | 3,137,234 | 10,454,583 | 5,522,324 | \$ 1,486,671 |
| Box Elder | 3 | 6,718 | 254 | 1,205 | 622,206 | 15,832 | | 103,113 |
| Garfield | 3 | | 41 | 7 | | | | 854 |
| Grand | 2 | 18 | 25 | 4 | | | | 526 |
| Iron | 2 | 2 | 1 | 1,037 | 22 | | | 646 |
| Juab | 56 | 383,977 | 67,002 | 5,600,617 | 9,293,661 | 22,508,439 | 761,212 | 7,241,360 |
| Millard | 1 | 12 | | 12 | 36 | 6,193 | | 286 |
| Morgan | 1 | 52 | | 97 | | 23,994 | | 1,121 |
| Plute | 7 | 11,809 | 2,505 | 9,739 | 3,904 | 46,458 | | 60,312 |
| Salt Lake | 51 | 9,195,624 | 85,973 | 2,504,021 | 145,065,188 | 72,111,025 | 3,421,724 | 29,139,248 |
| San Juan | 1 | | 25 | 2 | | | | 518 |
| Summit | 15 | 216,293 | 3,591 | 3,090,282 | 1,343,846 | 32,617,400 | 2,459,783 | 3,721,982 |
| Tooele | 29 | 147,483 | 9,804 | 640,249 | 1,522,596 | 14,619,866 | 1,202,568 | 1,535,994 |
| Uinta | 2 | | 20 | 2 | | | | 416 |
| Utah | 18 | 18,186 | 1,479 | 265,850 | 6,945 | 4,531,687 | 2,969,793 | 557,913 |
| Wasatch | 2 | 54,234 | 629 | 627,274 | 450,324 | 9,191,313 | 2,520,423 | 1,007,250 |
| Total 1913.... | 217 | 10,202,566 | 172,467 | 13,084,835 | 161,445,962 | 166,126,790 | 18,857,827 | \$44,858,210 |
| Total 1912.... | 207 | 7,770,270 | 206,360 | 13,835,903 | 137,307,485 | 140,311,135 | 17,067,177 | \$42,922,302 |

*Includes placer production.

The production of coal in Utah in 1913 was 3,254,828 short tons, with a value at the mines of \$5,384,127, compared with 3,016,149 tons worth \$5,946,451 in 1912, according to E. W. Parker of the U. S. Geological Survey. The increased production in 1913 appears to have been due principally to activity among metalliferous mines and smelters, as nearly all of the increased production was in the quantity of coal made into coke, this item alone indicating a gain of 225,561 short tons out of a total increase of 238,679 tons. Nearly 90% of the total coal production of Utah is mined in Carbon county, which contains a large part of the great Uinta basin. This county produced in 1913 2,830,102 short tons out of a total for the state of 3,254,828 tons. The industry was practically free from labor troubles in 1913, only one company reporting idleness from this cause, and only five men being disaffected. No strikes of any kind were reported in 1912, and only one of three days in 1911. Practically all the mines of the state work eight hours per day. According to statistics collected by the U. S. Bureau of Mines, there were 17 fatal accidents in the coal mines of Utah in 1913, a decrease of one from 1912.

JUAB COUNTY

All leases on the May Day property expired on June 1, and the owners will now develop the mine. Lessees have opened some new orchards. James C. Dick is manager.

WASHINGTON

SPOKANE COUNTY

Over 1 ft. of good lead ore has been opened in the Galena Hill mine, near Reardon, south of Spokane. W. S. Bliss is manager.

STEVENS COUNTY

(Special Correspondence.)—At a depth of 500 ft. in the Copper King at Chewelah, 4 ft. of gray copper ore has been cut 100 ft. from the United Copper boundary. Construction of a smelter at the Copper King mine is under way, and machinery is arriving. The Jay Gould mine is to be unwar-

ered, and developed under a bond. It has produced some high-grade silver-lead ore. A 1000-ft. adit is to be driven by the Big Bend Mining Co., which has bonded the Mayflower claims for two years.

The Big Bear mine, four miles from Marcus, is developing in a promising way, and a compressor plant has been installed. The Deer Trail district promises to be active during the coming summer. The Queen and Seal mines will prob-

ably be steady producers, the latter being an old silver producer, one of the oldest in the southern part of the county. The Cleveland mine is shipping ore to Tacoma. Springdale is the shipping point for the Deer Trail district.

Chewelah, May 24.

The annual meeting of the Copper King Mining Co., was held at Spokane on May 21. According to the president, S. P. Domer, there is 6000 to 7000 tons of 5% ore ready for the 100-ton per day smelter being installed. The mine is in good condition. A new air-compressor is to be added to the equipment. Nearly 4000 ft. of underground work has been done in the Liberty Mining & Milling Co.'s claims at Chewelah.

CANADA

BRITISH COLUMBIA

Free-milling gold ore has been opened at 1200 ft. in the War Eagle mine at Rossland. Mines in this district shipped 190 cars of ore to the Trail smelter during the two weeks ended May 21, 6572 tons from the Centre Star, 2650 from Le Roi, 848 from the Josie, and 848 from the Ben Hur at Republic, Washington. Charles W. Drysdale, of the Geological Survey of Canada, will examine the ore deposits of Ymir, and do some preliminary work in the silver-lead area of Windermere.

ONTARIO

During the last four-weekly period, the Hollinger mine produced 15,191 tons of ore, including 1013 tons from the Acme, averaging \$13.69 per ton. The mill recovery was 95.1%. All costs totaled \$4,349 per ton, and the profit was \$123,523. The mine continues to develop satisfactorily. The Buffalo mill at Cobalt treated 6767 tons of ore in April averaging 17 oz. silver per ton. Ore reserves in the Seneca-Superior lease of the Peterson Lake Silver Mining Co. are estimated by R. B. Lamb to contain 3,850,000 oz. The output in 1913 was 1,406,772 oz. worth \$828,578, of which the Company received a royalty of \$207,114, or 25%. The Coniagas company has started work on an old shaft in the town of Cobalt.

Personal

S. H. BALL is in Greenland.
 STEPHEN J. LETT is in Russia.
 MARK L. REQUA was in London recently.
 C. W. MERRILL was in New York last week.
 CHESTER W. WASHBURN has gone to the Congo.
 BAILEY WILLIS is coming up from the Argentine.
 ALTON L. DICKERMAN was in New York recently.
 COURTENAY DE KALB has left for Tucson, Arizona.
 B. C. GULLACHSEN has left the Rand and is in London.
 A. K. MACFARLANE, of Chihuahua, Mexico, is in London.
 D'ARCY WEATHERBE has returned to London from Ontario.
 ROWLAND C. FEILDING has returned to London from Spain.
 DONALD F. FOSTER has left West Africa and is in London.
 C. W. HAYES and family have returned to the United States.
 W. J. LORING expects to visit California during the summer.
 THOMAS H. LEGGETT has returned to New York from the West.

OTTO SUSSMANN has moved his office to 61 Broadway, New York.

MASON T. ADAMS is engaged on professional work in Kentucky.

NORMAN STINES, manager of the Sissert Estate, has been in London.

R. M. RAYMOND and W. W. RAYMOND have been at Rochester, Nevada.

JOHN H. CALLINAN, of Toronto, was recently at Rochester, Nevada.

WALTER G. PERKINS has gone to the Messina copper mine in the Transvaal.

T. A. RICKARD sailed for England on the *Kaiser Wilhelm der Zweite*, June 1.

E. A. WALLERS has been elected president of the Transvaal Chamber of Mines.

POPE YEATMAN has returned to New York from Chile and has gone to Nevada.

NELSON DICKERMAN, manager for the Pato company, Colombia, is in London.

J. H. CURLE returned to London from Abyssinia and has gone to Nicaragua.

PERCY A. ROBBINS has returned from Europe to the Hollinger mine, Ontario.

ALFRED JAMES was in New York on his return from Canada, and has gone to England.

E. E. HARDACH, manager of the Witwatersrand Deep, is on his way to Nevada, by way of London.

ARTHUR W. JENKS is in the United States and will not return to the Argentine for some months.

E. G. SPILSBURY was in Belgium last week and expects to return to New York about the middle of June.

R. GILMAN BROWN is making a tour of inspection to the Kyshtim, Tanalyk, and Ridder mines, in Siberia.

J. E. VAUGHAN, Government Inspector of Mines for the Union of South Africa, is on a visit in England.

PERCY E. BARBOUR has resigned the management of the property of the Uwarra Mining Co., Candor, North Carolina.

PHILIP L. FOSTER, representative of the Exploration Company in America, has moved his office to 62 Broadway, New York.

H. G. PEAKE, of the Union Construction Co., has returned to San Francisco after spending two years in tin dredging in Portugal.

LAWRENCE ADDICKS has resigned as manager of the refinery at Chrome, New Jersey, belonging to the United States Metal Refining Company.

JOHN H. EGGER has been appointed to the position of general manager for the Rochester Mines, Rochester Weaver Min-

ing, and Nenzel Crown Point Mining companies, to take effect June 1, succeeding N. M. WADE, who has resigned.

R. E. PALMER, consulting engineer for the Rio Tinto Copper Co., has taken up consulting work, with offices at No. 3 Lombard street, London.

ROBERT E. CRANSTON is making an examination of the Humboldt mine, in Ouray county. This property joins the Smugler Union on the north.

T. H. OXNAM, owner of the Gold Mountain mines, San Bernardino county, has returned to Los Angeles, after spending three months at the property.

FREDERICK BRADSHAW, general superintendent of the Tonopah Belmont Development Co., has been in British Columbia and has returned to Tonopah.

GEORGE A. LAIRD, who was for a short time in charge of the concentrator at Great Cobar, now idle, has opened an office as consulting engineer at Sydney.

HENRY TSCHETSCHOTT, professor of ore dressing at the University of St. Petersburg, Russia, is making a tour of California dredging and hydraulic workings, while en route to Alaska.

Operating officials in Korea of the Seoul Mining Co., of which H. COLLBRAN, of London, is president, and H. R. BOWTWICK, of San Francisco, is first vice-president, are as follows: general manager, A. H. COLLBRAN; auditor, J. S. COLLBRAN; resident engineer, W. T. HALL; superintendent of Tul Mi Chung mine, E. W. MILLS; superintendent of machinery, H. G. ENGLISH; superintendent of transportation, L. C. FAULK; Suan mine foreman, R. BLAMEY; Suan mill foreman, F. C. BROWN; and medical officer, E. DEM. STRYKER.

FRANCIS DUPEN, a mining engineer in the employ of the Miami Copper Co., was instantly killed, on May 26, by falling 350 ft. to the bottom of No. 1 shaft. He was a former Lake Superior man, who had worked with the Phelps-Dodge company at Bisbee and later was at Silver City, New Mexico.

Schools and Societies

The UNIVERSITY OF UTAH, at Salt Lake City, is to erect a Greek theatre, modeled after that at the University of California, to seat 2500 people. Subscriptions are now being received. A fine site has been secured overlooking the valley. The Wasatch mountains to the east, and the city, lake and smelters to the west.

The new STATE SCHOOL OF MINES will open at El Paso, Texas, in September, in charge of S. H. Worrell, at present chemist of the University of Texas. The last legislature made an appropriation of \$15,000 for equipping the institution, and to pay salaries of instructors for the first year. The city has raised \$50,000 for the buildings and ground.

The report of the Colorado Scientific Society for 1913 states that material progress was made. Nine meetings were held, with an average attendance of 22 members. The present membership is 238, of whom 143 reside in Denver. Additions were made to the library by purchase and gift. Receipts for the year were \$2458, and expenditures \$2314, leaving cash on hand of \$144. The report includes a discussion on 'Systematic Testing in the Evolution of Mill Practice,' by George E. Collins.

PRINCETON UNIVERSITY department of geology first term of the year 1914-15 begins on September 23. There are 18 members of the faculty. The department is housed in Guyot hall, which has a floor space of 85,146 sq. ft., and cost \$425,000 in 1909. The museum occupies 9000 sq. ft. of floor area. Graduate students, unless holders of a fellowship or scholarship, pay an annual tuition fee of \$30. The average residential cost to students ranges from \$8.33 to \$12.50 per week.

New York Metal Market Review

Business in metal products has not been good in May, and raw materials have felt the slackened demand. The best feature at the moment is a better sentiment, but this will not hold long unless buying improves. Much depends upon the railroad freight rate decision, which is hoped to be near at hand. Railroad supplies are notoriously low, and the most unusual makeshifts are being resorted to in the avoidance of buying. Whether the decision is favorable or not, much improvement in buying by the railroads must result from even partly raising the embargo on the activities of the purchasing agents. On the whole, the prices of all metals weakened in May. In copper, a tendency to raise quotations before consumers really take hold is noticeable, which second-hands have used to their advantage. The base price of hot rolled sheet copper was twice reduced during the month. As a result of the prolonged strike in the Lake Superior district, some consumers are now using electrolytic where they formerly considered Lake in-

on May 8 of the Copper Producers' statement, which showed production for April to have been 151,500,531 lb., an increase of 5,848,549 lb., while deliveries decreased 13,641,666 lb., there was moderate selling of electrolytic by agencies at 14.12½c. cash New York. Dealers' prices eased off still more, the reported quotations going as low as 14c. cash f.o.b. New York, but metal at this price was not easy to find. During the remainder of the month, or at least until May 26, electrolytic did not vary much from 14.12½c. cash New York, and business was not heavy at any time. There was a flurry toward the middle of the month, and sellers again tried to advance their prices ¼c. per pound, but there was too much metal to be had at a lower figure to make the advance effective, and, as a matter of fact, lower rather than higher prices could be obtained. It developed that about the only real busy consumers were the manufacturers of ammunition, many of whom use Lake copper exclusively. This was one of the few good results of the trouble in Mexico. The demand for rolled copper was poor, and in the last half of May the price of hot rolled sheets was reduced twice ¼c., making the base

dispensable. Tin dropped heavily abroad on adverse reports from the Straits Settlements, and again following the Banca sale. Lead started the month strong, but finished rather weak. The net change in spelter was a small decline, the slack business of the galvanized sheet mills having been felt. Antimony presented little of interest. Aluminum was without any interesting feature and May finished with prices a little lower for both prompt and future metal.

COPPER

Around 14.12½c. cash, New York which was quoted at the end of April, a fair business developed, but it was checked by an advance to 14.37½c. delivered 30 days, or 14.25c. cash New York, at which price May was ushered in. Consumers did not take kindly to the advance, and concessions were offered by first as well as second hands. After the appearance

150½c. per pound. Since the beginning of 1913, the following base prices have been announced: January 1, 20½c.; February 2, 20c.; March 13, 19¾c.; May 13, 19½c.; and May 22, 19½c. Lake copper lost about ¼c. in the month, the quotation May 1 being about 14.50c., whereas on April 26 the minimum was about 14.25c. Lake, which was abnormal both as regards supply and price, during the Lake Superior strike, has suffered in a way unlooked for, since certain consumers who formerly used it exclusively, and thought they must have it, found as a result of the stringency that electrolytic answered their purposes in a satisfactory way. It is probable that some will stick to electrolytic. In the latter part of the month the attitude of most consumers of copper was to buy as little as possible, some of those approached saying they had sufficient for three weeks or a month and that they saw

no reason for buying further ahead. In April 34,787 tons was exported, and in May 31,948 tons. The Waterbury average for April was 14.87½ cents.

LEAD

From May 1 to 29, quotations for lead were stationary at 2.90c. New York, and 3.80c. St. Louis. In the early part of the month the tone was good and an advance was looked for, but it did not materialize. The outlook at that time was so good that some sellers were disinclined to sell far ahead. About the middle of the month there were some transactions in futures and premiums were paid. At this time it was noted that the London price had been advancing steadily, and exports were again becoming a probability. Subsequently, however, London declined, and with it went some of the strength of the New York market. Toward the end of May the situation was one of waiting on the part of consumers.

SPELTER

This metal has felt the decline in demand for galvanized sheets, but otherwise there is little to say in comment upon

SPELTER PRICES, NEW YORK AVERAGED FOR 10-YEAR PERIODS.

it. In the first 10 days of May, producers stiffened their prices, the advance being from 5c. New York to 5.15c., but little additional business was forthcoming, and about May 15 quotations dropped 5 points, and the market was easy at 5.10c. New York and 4.95c. St. Louis.

TIN

To sellers, at least, tin was a rather unsatisfactory metal in May, prices both at home and abroad showing recurrent weakness. Average prices on the days specified were as follows: May 1, 34.10c.; May 5, 33.10c.; May 11, 33.40c.; May 15, 34.45c.; May 20, 33c.; May 26, 33.25c.; and May 28, 31.87½c. In the first week of May, the low quotations caused interest in futures and resultant buying of August and September, some for July and less for June; but, all told, it did not amount to a great deal. On May 11, there was notable buying of futures. About this time the big London houses were worried over the almost steady decline in prices and took steps to get together to prevent further weakness. Conditions were getting to a pass where some of the operators would be unable to fulfill their contracts, which would be to the detriment of the entire trade. The reported getting together had a good effect on the New York market, but on May 18 London came down with a rush, £6 5s. being lost on that day, a decline which domestic prices followed, 20 points being lost in New York. The lower level caused a good run of orders in New York on the day of the decline, at least 250 tons being dealt in. The collapse in London was caused by reports that the May shipments from the Straits would be between 6700 and 6900 tons, the estimated figures being record breaking. Up to the time of these reports, the trade was confident of good business and higher prices were in sight.

Near the close of the month there was good buying on one or two days at the lower prices, the turnover on May 25 being about 300 tons for June and July delivery. Despite the realization of a fair price at the Banca sale in Holland, May 28, 2300 tons being sold at an average price of 91 florins, equivalent to 33.35c. c.i.f. New York, London again broke on that day with a decline of £4. The New York price dropped in turn and some small business was done at 31.87½c. Deliveries into consumption in April were good, amounting to 4300 tons, although deliveries for the first four months of this year show a decrease of 900 tons as compared with the same time last year. The total visible supply on April 30, 1914, was 15,447 tons, or 5625 tons above the total visible supply of April 30, 1913. The arrivals in May, up to May 29, were 3035 tons, and there was afloat 2235 tons. May deliveries were 3800 tons, and in stock and landing May 31 was 1773 tons. The tin plate business has been good.

ANTIMONY

This metal varied but little in price in May, and generally was without interest. Quotations, when the month opened, were about 7.25 to 7.35c. for Cookson's, 6.75 to 6.95c. for Hallett's, and 5.75 to 6.50c. for other grades. At the end of the month Cookson's and Hallett's could be had five to ten points lower. Prices gained a little at one time in the month because of speculative influences, but the gain was lost because of pressure to sell from the same sources. At last reports, accumulating stocks had weakened the situation.

ALUMINUM

Features were lacking in this metal. About the middle of the month the quotation for prompt, 98 to 99% pure, was 17.87½ to 18.12½c., with futures at 17.75 to 18c. The tone at this time was somewhat better, but not much business was transacted. At the end of May quotations were 17.75 to 18c. for both prompt and futures. London price is from £81 to £83 per ton.

Production of Secondary Metals in the United States in 1913

The production of secondary metals in 1913, according to the United States Geological Survey, was as follows:

| Metal. | Short tons. | Value. |
|---|-------------|--------------|
| Secondary copper, including that in alloys other than brass | 66,980 | \$20,536,068 |
| Remelted brass | 99,315 | 24,651,969 |
| Secondary lead | 33,104 | |
| Recovered lead in alloys | 39,730 | 6,409,392 |
| Secondary spelter | 50,995 | |

Total value\$72,844,996

The tonnage of metals treated in 1912 was practically the same as 1913, but the value of the last year was \$4,550,847 greater.

MACHINERY manufactured in Switzerland in 1913 was valued at \$27,770,000, about 75% of which was exported. It consists of electric generators, water-power apparatus, steam engines, gas, petroleum, and benzine motors, and other industrial machinery.

The Metal Markets

LOCAL METAL PRICES

San Francisco is not a primary market for the common metals except quicksilver. The prices quoted below therefore represent sales of small lots and are not such as an ore producer could expect to realize. Ore contracts usually call for settlement on the basis of Eastern prices, less freight and treatment charges. The prices quoted are in cents per pound, except in the case of quicksilver, which is quoted in dollars per flask of 75 pounds.

San Francisco, June 4.

| | | |
|---------------------|-----------------|----------------------|
| Antimony | 9 | — 9 $\frac{1}{2}$ c |
| Electrolytic copper | 15 | — 15 $\frac{1}{2}$ c |
| Pig Lead | 4.15 | — 5.10 |
| Quicksilver (flask) | | \$39.00 |
| Tin | 39 | — 40 $\frac{1}{2}$ c |
| Spelter | 6 $\frac{1}{2}$ | — 6 $\frac{3}{4}$ c |

Zinc dust, 100 kg. zinc-lined cases, 7 $\frac{1}{2}$ to 8c. per pound.

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, June 4.—Copper is reported weaker, and the spelter market is lifeless, while lead is firm. Copper shares are a little firmer, but the Stock Exchange is having a quiet time. The Anaconda output for May was 23,500,000 lb. Both Mohawk and Wolverine yields were a large increase over April. At St. Louis lead is quiet at 3.80 to 3.82 $\frac{1}{2}$ c., and spelter is dull at 4.97 $\frac{1}{2}$ c. Bar silver in London is dull at 25 $\frac{3}{4}$ d. (51.5 cents).

SILVER

Below are given the average New York quotations in cents per ounce, of fine silver.

| Date | Average week ending |

| May..... | 60.21 58.21 |
| June..... | 59.03 57.73 |

A clear conception of the relative position occupied by Mexico as a producer of silver can be obtained by supposing a bar, 1000 oz. in weight, to be composed of metal drawn proportionately from the different countries which contribute to the world's supplies. Basing the figures on the returns for 1911, 350 oz. would be of Mexican origin, so that the 1000-oz. bar would shrink automatically to 650 oz. if Mexican supplies entirely ceased, according to Samuel Montagu & Co., of London. Further, 267 oz. would be from the United States, and 145 oz. from Canada. Thus, 762 oz., more than three-quarters of the bar, would be obtained from the North American continent alone. The remaining 238 oz. would be obtained as follows: 75 oz. from Australasia, 75 oz. from Europe, 62 oz. from South and Central America, 22 oz. from Asia, and 1 oz. from Africa. The way in which the bar would be divided in proportion to the consumption of the different continents is more difficult to ascertain, for statistics both of coinage and manufacture include old material reworked, and, though the total amount used for coinage is fairly constant, its distribution as regards different countries varies year by year. One thing is very certain, Asia, which only contributes 22 oz. of the bar, absorbs the lion's share, and is prepared to utilize, in one form or another, over 500 oz. of the weight.

COPPER

Quotations on copper as published in this column represent average wholesale transactions on the New York market and refer to electrolytic copper. Lake copper commands normally 1-5 to 1-6c. per lb. more. Prices are in cents per pound.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

| Week ending | May 21..... | May 28..... | June 4..... |
|-------------|-------------|-------------|-------------|
| May 7..... | 39.00 | 39.00 | 39.00 |
| " 14..... | 39.00 | 39.00 | 39.00 |

Monthly averages.

| June..... | 41.00 | Dec..... | 40.00 |

TIN

New York prices control in the American market for tin, since the metal is almost entirely imported. San Francisco quotations average about 5c. per lb. higher. Below are given average monthly New York quotations, in cents per pound:

Monthly averages.

| 1913. | 1914. | 1913. | 1914. |
|-----------|-------|-----------|-------|
| Jan..... | 59.15 | July..... | 49.70 |
| Feb..... | 49.07 | Aug..... | 41.75 |
| Mar..... | 46.95 | Sept..... | 42.45 |

| June..... | 45.10 | Dec..... | 37.57 |

The Old Dominion company has declared a quarterly dividend of \$1 per share, making \$3.25 for the current year; also, its subsidiary, the United Globe company, will pay \$1 per share, making \$8 for this year. On July 1 the Belmont company will pay 25c per share, or \$375,000, and the Extension will pay 7 $\frac{1}{2}$ c. per share, or \$70,750. Profits of the latter company for the year ended March 31, 1914, were \$82,126. West End profits in May were \$43,336 from 5760 tons of ore.

The *Bulletin* of the Pan-American Union, of Washington, states that radium-bearing ore has been discovered in San Salvador, and thus is the radium bill further complicated. The deposit in Central America was found at Cerro Pelon, and an Englishman is credited with the discovery. As a result, two qualified engineers have been sent to make further and more detailed investigations, and in their research they are said to have drilled already 200 ft. The land where the mine is, belongs to the municipality of Sensuntepeque, and already it is proposed to lease this land for a period of years on a basis of 10% of the profits.

Current Prices for Ores and Minerals

(Corrected monthly by Atkins, Kroll & Co.)

The prices are approximate, subject to fluctuation, and to variation according to quantity, quality, and delivery required. They are quoted, except as noted, f.o.b. San Francisco. Buying prices marked *.

| Capital stock | \$153,887,900 |
| 5% gold notes | 12,500,000 |
| Accounts payable | 11,927,523 |
| Profit and loss surplus | 23,639,139 |
| Total | 201,954,562 |

CHINO COPPER COMPANY

This Company's mining property in New Mexico amounts to 2645 acres. The area controlled for mill-sites and water rights contains 16,700 acres. During 1913 no drilling was done for the sole purpose of developing additional ore reserves. Nineteen holes, aggregating 10,593 ft., were drilled to make sure that waste was not dumped on ore-bearing areas. These holes proved increases in the extent of certain orebodies. Ore reserves are estimated at approximately 90,000,000 tons averaging 1.8% copper, and are somewhat higher than those for the previous year. There are now 10 steam-shovels, 19 locomotives, and 20.3 miles of track at the mine. Overburden moved was 3,082,174 cu. yd., and ore mined 1,976,572 tons. Waste removed to date totals 8,822,000 cu. yd. The average cost of steam-shovel work was 36.87c. per yard, against 29.14c. in 1912. Mining was hampered by the limited areas in which the shovels could work and avoid interfering with stripping operations. No important additions were made to the mill. All sections, while in commission, worked 93.6% of the possible time, and treated 1,942,700 tons of ore averaging 2.033% copper, with 67.31% recovery. Concentrate produced amounted to 183,116 tons assaying 14.518% copper. The metal production was 53,170,145 lb. Financial results were as follows:

| | |
|--|-------------|
| Revenue from copper at 15.0884c. per pound..... | \$7,621,419 |
| Mining, treatment, stripping, selling commission.. | 4,431,126 |
| Operating profit | \$3,190,293 |
| Miscellaneous income | 137,533 |
| Total profit | \$3,327,826 |
| Interest, income tax, etc. | 93,793 |

GREENE CANANEA COPPER COMPANY AND SUBSIDIARY COMPANIES

This Company owns 954,442 out of 1,000,000 shares in the Greene Consolidated Copper Co., which in turn is largely interested in the Cananea Consolidated Copper Co. Greene Cananea also controls the San Pedro Copper Co. Operations of the Companies are centred at Cananea, Sonora, Mexico, and

the combined reports cover the calendar year 1913. During the term, Greene Cananea received dividends amounting to \$1,050,000 from the Cananea Consolidated, and paid dividends totaling \$950,000.

The general manager of Cananea Consolidated, J. S. Douglas, reports as follows concerning operations last year: The revolution in Sonora affected all work from time to time, necessitating partly closing down the smelter. Ore extracted from the various mines was as follows: Elenita, 4839; Puertecitos, 54,458; Henrietta, 3940; Elisa, 90,826; Pro. of Sierra de Cobre, 72,976; Capote, 164,611; Oversight, 88,857; Veta Grande, 90,257; Kirk 15, 1,526,675; Kirk, 42,234; Cobre Grande, 20,025; and Chivatera, 13,838; also lessees, 1498; a total of 673,034 wet tons. Costs of mining were \$2.89, ranging from 58.5c. to \$12.36 per ton. The Puertecitos mine is opening fairly satisfactorily; lessees have mined a little good ore from the Henrietta; an important 4% orebody has been partly developed in the Elisa; the Eureka does not look well; at 200 ft. in the Sierra de Cobre, adjoining the Eureka, a promising 4% orebody is being opened; the Capote is generally in good condition; prospects in the Oversight are decidedly interesting; in the Veta Grande, the Massey orebody contains 70,000 tons of 4% clayey ore, and between 200 and 300 ft. there is 75,000 tons of 5% silicious ore blocked out; the Kirk shaft is down 900 ft.; while nothing has been done in the Cobre Grande since March 1913. Development totaled 49,505 ft., of which 800 ft. was shaft-sinking. In June, nearly all development was changed to the contract system, resulting in reduced cost.

The concentrating plant treated 343,081 wet tons of ore, of which 42,072 tons was from the Cananea-Duluth. Three Hardinge mills were installed, and, not including them, the cost was 7.16c. per ton. Including custom ore and 46,248 tons of Miami concentrate, the blast-furnaces treated 567,434 dry tons of copper-bearing material at a cost of \$2.54 per ton. Two reverberatory furnaces worked 537 furnace-days, with an average charge of 226 tons per day, at a cost of \$1.67 per ton.

The Great Falls type converters reduced the cost of converting copper by a total of \$9.13 per ton for the year. Arthur C. Cole was in charge of the smelter, and Frank J. Strachan at the concentrator. The total net cost of fine copper sold was 9.547c. per pound. Results may be summarized as follows:

| | |
|---|------------|
| Ore treated from all sources, tons (Company ore, 2.4% copper) | 757,460 |
| Copper from Company ore, pounds..... | 33,205,160 |
| Copper from custom and Miami ore, pounds..... | 42,806,847 |
| Silver in Company bullion, ounces..... | 1,069,746 |
| Silver in other bullion, ounces..... | 428,192 |
| Gold in Company bullion, ounces..... | 5,438 |
| Gold in other bullion, ounces..... | 2,583 |

Greene Consolidated and Cananea Consolidated combined statement:

| | |
|-------------------------|-------------|
| Revenue | \$7,576,138 |
| Expenditure | 5,389,878 |
| Net income | 2,186,260 |
| Balance from 1912 | 3,776,321 |
| Total surplus | 5,962,581 |
| Dividends paid | 950,000 |
| Balance for 1914 | 5,012,581 |

The San Pedro Copper Co. reports that 93,199 tons of ore averaging 2.059% copper, 2.020 oz. silver, and 0.0115 oz. gold per ton was treated, and 42,072 tons was milled, yielding 8647 tons of concentrate. The metal yield was 3,839,030 lb. copper, 188,293 oz. silver, and 1076 oz. gold. The income was \$709,747, and net profit \$158,332. Adding the balance of \$345,889 from 1912, the amount available was \$504,221, of which \$225,000 was paid in dividends, leaving a surplus of \$279,221.

Development in the Cananea-Duluth mine totaled 4885 ft. Mining cost \$2.59 per ton of wet ore. The mine has not been worked since March 8, 1913. All ore is treated at the Cananea Consolidated plant.

Decisions Relating to Mining

MINING CONTRACT—RESCISSION DENIED

Under a mining contract, the defendant was required to discharge certain liens on the property in question and if it thereafter elected to continue operations, to pay to plaintiff royalties up to a sum which added to the amount of outstanding liens would aggregate \$200,000. After discharging the liens the defendant refused to continue operations claiming that the ore could not be profitably mined, but also refused to surrender possession. Plaintiff brought an action to recover possession in which defendant interposed a cross-complaint seeking a rescission of the contract and repayment of moneys expended. The only grounds claimed for rescission were that the plaintiff lacked title to 1/48 of the property. Held, that defendants could not maintain their position as they had not acted promptly upon discovery of the flaw in the title. Plaintiff's title quieted.

Gordon-Tiger Mining & Reduction Co. v. Brown (Colorado)
138 Pacific, 51. February 2, 1914.

ALASKA PLACER ACT OF 1912 CONSTRUED

A prospector, armed with a power of attorney from his partner, left for the Chisana goldfields in Alaska about September 1, 1912, having been grubstaked by his partner at Dawson. There was no general knowledge in Alaska at that time of the passage of the Act of August 24, 1912, requiring that powers of attorney to locate placers be recorded. The prospector located several placer claims for his partner, but on account of the severe winter and inaccessibility of the Chisana district was unable to get back to the coast and record the power of attorney and location notices until the following August. In the meantime a locator made a location on the same ground subsequent in date to the first prospector and brought suit in ejectment against the prior locator on the grounds that he had failed to record his power of attorney before locating. Held, that the order in which the acts of location are performed is immaterial, that recording the power of attorney is one of the acts of location in Alaska, that having acted in good faith and with due diligence considering climatic and geographical conditions, the first locator should be protected in his location, even though his power of attorney was not recorded until after the location was made.

Likaits v. Johnson, District Court of Alaska, (not yet reported). March 18, 1914.

Industrial Progress

A Ball Tread Tractor

Yuba ball tread tractors are manufactured by The Yuba Construction Co. in its plant at Marysville, California. For the past ten years this Company has been building gold dredges, suction dredges, and irrigating pumps. The same engineering skill and mechanical accuracy that is reducing delays to a minimum in gold dredges is exercised in building the ball tread tractors. Tractors can well be used in the lumbering industry to perform more work than almost any other mechanical contrivance. Their great power and broadtractive area make them particularly suitable for hilly country. This type of machine can be used not only to haul supplies and machinery into the camp, but in the actual work of lumbering as well. Wherever 12 and 18 horses are used in freight-

so that the wear on the bearings is taken up from below.

On each of the drive shafts is a marine type reversible clutch. Each clutch is controlled by a separate lever from the driver's seat. In this feature lies the secret of the tractor's short-turning ability. The treads are totally independent of each other. One may be going ahead while the other is reversed without putting any undue strain on any part of the transmission. The endless-belt tread was adopted and improved by eliminating the loss of power suffered by the sagging of the upper portion when under load. The ball tread is mounted on a rigid cast steel frame, so designed that it is kept taut at all times. Instead of running the machine over the track on a modified railway truck, the ball-bearing principle has been enlarged and adapted to the tractor. All the weight borne by the treads of the ball tread tractor is carried by large balls, which distribute it evenly over the entire ground-bearing area of each tread. By this means a pressure per square inch on the treads was gained low enough to enable the machine to run over the soft ground without packing it. The balls are made of chilled cast iron, which gives wearing qualities closely equaling

BALL TREAD TRACTOR HAULING 8 TONS OF DREDGE BUCKETS UP A 16 PER CENT GRADE.

ing work the tractor can be used. In one of these machines the power of 12 and 18 horses is compressed until it occupies only as much road space as two horses. This becomes a decided advantage when it is necessary to make short turns on mountain grades. The tractors will operate in soft ground or sand where horses would have extreme difficulty, and streams shallow enough to prevent water reaching the carburetor air intakes can be forded without damaging the mechanism in any way. Their use in connection with mining operations has demonstrated tractors to be invaluable in many instances. The accompanying illustration shows a Yuba tractor in use for freighting buckets to a dredge over a 16% grade. In the manufacture of tractor machines an endeavor is being made to gain greatest strength with least bulk and weight. An ample margin of safety must be put into every portion of the machine. Each part must be made strong enough to withstand much greater strains than it will be called upon to bear in the course of ordinary work.

Model 12 Yuba tractors are equipped with 40-hp. L-head type motors. In the model 18 machines, a 55 to 60-hp. T-head type motor is used. Both motors are built for heavy duty. In order to gain lightness of weight, flexibility, and at the same time produce high power, a long stroke with proportionately small bore is used. In adapting these motors to Yuba ball tread tractors, they have been adjusted to operate normally at about 70% of their maximum speed, to insure longer life to the parts. This method allows a better margin to carry a heavy load through bad spots on the road without stalling the engine. Crank-shafts are supported in such manner as to reduce wear. This is accomplished by the use of unusually long bearings and by designing the crank-case

those of the highest-grade turned steel balls at a small part of the cost. When it becomes necessary to replace either or both, it can be done in the field by the operator. The manganese steel track links of a Yuba tractor will not easily pack with earth or mud. This advantage was gained by making the links with the grouser in the centre. The only place earth can pack is between two links. When the track is picked up from the ground the links turn through a sufficient angle so that any earth packed there breaks and drops off, leaving the tread clean. If earth or sand occasionally gets through the overlapping shoes into the ball bearings of the track, it is claimed no harm will result, as the size of the balls is such that any particles are immediately crushed and thrown out again.

AS CONSIDERABLE publicity was given last fall to a suit brought by George E. Blakeslee against the International Motor Co. *et al.*, the Company has issued a statement from its office to the effect that on May 14, 1914, Mr. Justice Manning handed down a decision which appears effectively to end the litigation. In dismissing the complaint against the International Motor Co., the judge did so because no facts were shown sufficient to constitute a cause of action against the Company.

MECHANICAL oil-burning systems are attracting increased attention of late, due to the ever-increasing use of this type of fuel. The Coen Co., of San Francisco, has recently prepared a series of evaporative tests on steam boilers fired with mechanical oil-burning equipment which present interesting data on this subject.

CABLE advices report that the borax holdings of Mr. F. M. Smith have recently been transferred to an English syndicate headed by the former minority holders of the shares. This marks the passing of one of the mining industry's unique characters and gives to the syndicate the present control of the world's output of borax. The sale price of the borax properties is reported at \$4,000,000 together with the taking up of \$4,000,000 bonded indebtedness of the company. We discussed the difficulties of the situation in detail May 23, and the outcome of the venture will be watched with much interest. Mr. F. M. Smith, like other of the industry's successful men who have sought new fields for investment, found his judgment poor and foresight blunted, with the result that the fortune amassed in mining has been largely lost in other investments and speculations.

ANOTHER district court has held that there was no sufficient authority in law for the so-called presidential land withdrawals. Mr. Justice M. T. Dooling at San Francisco having followed his Wyoming associate in so ruling. No circuit court has passed upon the matter, which, instead, has been certified to the United States Supreme Court. That body will in time deliver an opinion which will be final. In the meantime it is idle to speculate as to the outcome. There are good lawyers who hold that the authority of the President, acting through the Secretary of Interior as custodian of the public lands, is ample to the purpose. However this may be decided, the practical effect hoped for from the initial withdrawals has been accomplished: that is, monopolization of the public lands by speculators has been checked, and there is now clear and undisputed authority in the hands of the President to withhold lands from entry as it may appear to him necessary or wise.

CHILE, as was true of ancient Athens, draws revenue from mines instead of assessing taxes against its citizens. As Mr. and Mrs. Hoover have reminded us, it was the ores from Larium that paid for the fleet which preserved the independence of Greece. Chile, too, has built a fleet, but fortunately not all the public revenue is needed for that purpose and much of the money derived from nitrate royalties is going into railroads and other profit earning enterprises. Thus

the temporary wealth afforded by the mines is being reinvested in such shape that drying up of the present source of 80 per cent of the public revenue will not result in disaster to the country, as happened when Peruvian guano beds were exhausted. An industry which is so vitally connected with the life of a nation, to say nothing of its world relationships, is well worth study, and we are glad to present this week the first part of an exhaustive review, written by Mr. Lester Strauss, long familiar with the industry and a recent re-visitor to the nitrate regions. In preparing these articles, Mr. Strauss has had the friendly assistance of Mr. S. H. Loram, who wrote for us admirably on the same subject in 1910, and various other engineers and managers in the field. His articles will be found not only timely but most accurate.

DECLINE in the amount of work of the mineral division of the United States surveyor general's office of the state of Utah will probably result in the suspension of this office, according to a recent report from Salt Lake City. The decrease in the number of patented mineral claims is attributed to the fact that of recent years mining men have almost abandoned the idea of securing patents for mineral lands in the state on account of the many technical and adverse rulings of the department. This, coupled with recent stringency of the money market which has curtailed investment in mineral lands, has resulted in the local force being cut from nine men to one.

IN the thoughtful and suggestive address delivered at the Columbia semi-centennial by Mr. Hennen Jennings, two facts, in particular, are brought out that are not often appreciated by the man in the street, and perhaps seldom more than dimly apprehended by the men in the thick of mining work. These are the extreme modernness of big mining, and the fact that almost the whole of our present full flowered material civilization is due to the extra hands set to work by the miner. It is true that mining itself is very old. How old no one rightly knows, though in a fascinating article in *The Mining Magazine* for May, Mr. Courtenay De Kalb shows that in biblical times it was a well established industry. It was not, however, until the last few decades that mining became a big industry. It was only during the war of 1812 that development began in the Pennsylvania coalfields, and it was many years later that the great coal and iron industries of the East made their rapid growth. The ancient world depended upon the capricious winds, on beasts of burden, and on slaves to do its work. The modern world depends upon fuel and metals. Slavery was abolished in the United States years ago, but in the fuel annually mined and set to work, each man, woman, and child in the United States enjoys the equivalent of 27 slaves working continuously without food or sleep. Is it any wonder that we moderns have more things than our forefathers?

The Canal

May marked the beginning of a new era in the maritime commerce of the world, as it saw the passage of the first self-propelled boat through the Panama canal. While the formal opening has not as yet taken place, the tug *Mariner*, towing barges No. 11 and 15, left Cristobal at 6 a.m. on May 19 and arrived at Balboa at 6:40 p.m., thus making the first direct voyage from ocean to ocean by way of the canal. The magnitude of this great engineering work is imperfectly appreciated, we believe, by a great part of the American people, who look upon canal construction as a simple operation and think of the Panama canal as a ditch such as those inland waterways constructed by our forefathers of fifty years ago, most of which, by the way, are now idle or abandoned because of inability to compete with railways. The decade since the transfer of the canal property on the Isthmus from the second French company to the United States, May 4, 1904, has been one of intense activity in the canal zone, and great credit is due to those who have contended successfully with nature's barriers and made the new waterway.

The Panama canal is generally looked upon as a modern development and few realize that an inter-oceanic canal was the subject of serious consideration as much as four centuries ago when Angel Saavedra made the proposal to build a canal across the Isthmus of Darien. Again in 1550 Antonio Galvao made an investigation of possible inter-oceanic canal routes and suggested four different lines, among which was the Panama route which four and a half centuries later was to be actually utilized. The Isthmus of Tehuantepec was looked upon with favor in the early part of the past century and a canal survey was made in 1821 by General Obegoso. Twenty years later, in 1842, a concession was granted to Jose de Garry for the construction of this canal.

The first detailed study of the Panama route was made under the auspices of Simon Bolivar when president of Colombia. He caused Messrs. Lloyd and Falmare to study the subject and a report was published in the *Philosophical Transactions*, London, in 1830. This early plan included a railway from Panama to the Rio Trinidad, a tributary of the Chagres river, and harbor improvements on the bay of Limon; however, nothing tangible was accomplished. The French government next investigated the subject and in 1843 a French engineer, M. Napoleon Garella, was sent to the Isthmus. He advocated a sluiced canal, but the size of the project was beyond the facilities for canal construction of that time and the French government decided against it. The discovery of gold in California in 1849 gave new impetus to the project and an American company took the matter under consideration. With Messrs. Totten and Trautwine, who had been prominent in connection with the Cartagena-Magdalena canal, in charge, it was decided to build an isthmian railway which, after innumerable difficulties, was completed in 1855.

The first reconnaissance of the present waterway

was the result of a discussion of the subject before the *Congrès des Sciences Géographiques* at Paris in 1875 and a society under General Türr was formed for making the necessary explorations. In 1876 Lieutenant L. N. B. Wyse went to the Isthmus at the head of an expedition for this purpose. In 1878 the Colombian government granted the Civil International Inter-oceanic Canal Society the exclusive privilege of constructing a canal through Colombian territory and at this time the ports and canal were neutralized. In 1879 M. Ferdinand de Lesseps became interested in the project and the first meeting of his company was called in 1881. This may be looked upon as marking the actual beginning of the present canal. The cost was estimated at 600,000,000 francs. The Panama canal was purchased for \$20,000,000 and the canal contractors Couvreur and Hersent began operations in October of the same year. The work of the de Lesseps company was conducted at the cost of millions of francs and thousands of lives. It involved such immense expenditures that it was finally abandoned and the thousands of contributors to the scheme faced a loss. The storm of indignation forced the French Chamber of Deputies to vote for a committee of inquiry and the prosecution of the canal directors. The inquiry began on December 24, 1892, and the loans of 1884 and 1888 were fully investigated. Names prominent in this investigation were Ferdinand de Lesseps and his son Charles, Marius Fontaine, Barron Cottu, and M. Eiffel, builder of the tower bearing his name. After a trial on the charge of giving and receiving bribes, the de Lesseps, Eiffel, Fontaine, and Cottu were sentenced to five years imprisonment, but were released later.

The first American canal commission was appointed by President McKinley in 1899 with Rear Admiral John Grimes Walker as chairman. After an examination of the proposed Nicaragua and Panama routes the commission reported in favor of Nicaragua. After considerable debate in Congress, in March 1902 the House passed a bill in favor of the Nicaragua route, which bill was rejected by the Senate. Soon thereafter a protocol known as the Hay-Herran treaty was signed by the United States and Colombia. The former agreed to pay \$40,000,000 and the latter to grant certain concessions for the right-of-way across the Isthmus for a Panama canal. This was ratified by the Senate of the United States, but rejected by the Senate of Colombia, which demanded more money. This action caused general dissatisfaction in Panama and led to the secession of that state. The United States aided Panama in the establishment of an independent republic and after it had been recognized a treaty was made for the building of the canal, the sum of \$10,000,000 being paid to Panama. The transfer of the holdings of the New Panama Canal Company to the United States from the French was effected on May 4, 1904, the consideration being \$40,000,000.

The second Isthmian Canal Commission assumed charge in March 1904. In 1905 a board of consulting

engineers was created. It consisted of eight American and five European members. This board visited the Isthmus and in January 1906 reported in favor of a sea-level canal, the vote being 8 to 5 in its favor. The minority at the same time presented a report favoring a lock canal. After the receipt of the report by the Isthmian Canal Commission this body recommended the adoption of the minority plan of a lock canal, which plan received the support of the Secretary of War and the President. The latter submitted this plan to Congress and it was adopted.

The work was carried on under civil engineers appointed by the President until February 26, 1907, when Colonel George W. Goethals of the engineering corps of the army was placed in full charge and under his able supervision the canal has been pushed to completion. Much of the credit must, however, be given to Messrs. Wallace, Shonts, and Stevens and the engineers of the old commission, who organized the work and furnished the basis upon which the army engineers built.

The magnitude of the work which has been done will be better understood when it is recalled that the work of the French companies totaled 78,146,900 cubic yards of excavation, of which amount only 29,908,000 was of service to the United States. The total excavation by the United States totals approximately 183,000,000 cubic yards, the concrete work amounted to 4,568,000, and the fill totaled 21,800,000 cubic yards. During the course of active construction work, about 100 steam-shovels and 18 dredges with a total of 45,000 employees were at work. When everything is completed it is estimated the cost will amount to \$325,201,000 which includes \$20,053,000 for sanitation, but does not the \$40,000,000 paid to the French company nor the \$10,000,000 paid to the Republic of Panama.

What the completion of the canal means to the commerce of the world is attested to by the shortening of distances between New York and the Pacific ports north of Panama by a distance of 8415 miles and south of Panama by a distance varying from 8415 miles at Panama to 1000 miles at Punta Arenas, on the Straits of Magellan. From Iquique, the nitrate port of Chile, the distance will be shortened by 5200 miles. The voyage from Liverpool to the Pacific ports will be shortened by 6000 miles and from New York to the ports in the Orient will also be reduced, the voyage to Yokohama by Panama being 3721 miles shorter than by Suez; to Shanghai the distance is reduced 1629 miles, to Sydney 3806 miles and to Melbourne 2656 miles. New Orleans will be 581 miles nearer the Orient than New York.

Engineers are interested in the canal, not only because of the changes in transportation routes that will ensue but because of the many problems involved in the actual work of construction. In one sense it was a great job of mining since the Culebra Cut is not unlike one of the great iron mines of the Lake Superior region and much of the work on the Pacific end was

done with machinery and by methods developed by the hydraulic miners of the Pacific slope. Incidentally many of the steam-shovels used and much of the equipment has been re-sold to the Chile Copper Company and will be used in the open pit work at that great mine where a larger amount of material is to be handled than was excavated in making the canal. In fact the canal, while a large order, is not unique as a piece of excavation and the political and financial problems involved were really larger than those in engineering.

The engineers have done their work. They have made the canal. It will rest with the statesmen and the captains of industry to say what the canal shall mean to the world.

Development of Leaching Practice

The recovery of copper from its ores by wet processes is gradually developing out of the chrysalis stage of experimental work into the mature form of routine practice. Large plants are under construction for the Anaconda, Utah, and Chile Copper companies, and at several other places experimental work is well advanced. The use of sulphuric acid as a solvent is general in the present state of the art. The proposed practice at the Chile Copper mine was fully discussed in our issue of May 2 by Mr. E. A. C. Smith, who has had direct oversight of the experimental work. The Utah Copper Company is about to build the first 2000-ton unit of a 10,000-ton leaching plant to treat the oxidized ore which overlies the sulphide orebody. At both the plants the ore will be coarsely crushed, in order to keep the production of slime at a minimum, and then leached with sulphuric acid. In Chile, the resulting copper sulphate will be electrolyzed; in Utah the intention is to precipitate the copper on iron for the present at least. At the Chile property electric energy can easily be generated by a power-plant on the seacoast, while iron would require to be brought from a considerable distance. In Utah, scrap iron is available, and since its use does not require the solution of any technical problems, the management of the Utah Copper has wisely decided to postpone experiments with electrolytic precipitation until the other details of practice have been completely worked out in the first unit of the plant.

Both the Chile and Utah companies have unusually favorable conditions in that the copper is present in such a form that it can readily be dissolved from coarsely crushed ore and without requiring a preliminary roast. Another somewhat paradoxical advantage is that the ore at both mines does not contain gold or silver in sufficient amounts to make their recovery worth while. Gold and silver can only be extracted along with the copper at the cost of complicating the process, and for an ore of a given value per ton, it is much better to have all metallic content copper, rather than in part precious metals. The work which has been done by the Anaconda Copper Mining Company during the past year in its 80-ton experimental

leaching plant is the more instructive, therefore, since it is necessary both to roast the ore before treatment with acid and to take steps to recover the silver present. The plant and proposed method were fully described in a paper presented by Messrs. Frederick Laist at the Butte meeting of the American Institute of Mining Engineers last summer, and the details of the results attained in the year's work will be presented by Messrs. Laist and Harold W. Aldrich at the meeting in Salt Lake City next August. So much interest attaches to the valuable pioneer work being done at Anaconda by these gentlemen, under the direction of Mr. E. P. Mathewson, that a brief summary of the work which has been done at Anaconda will be of service.

The material which is being subjected to the leaching process is the sand tailing from the concentrating plant. This contains 13 to 14 pounds of copper per ton and 3 per cent sulphur. Of this material about one-half is reclaimed on a 40-mesh screen and only 5 per cent will pass 200-mesh. This is roasted in a 6-hearth, 20-foot McDougall roaster, which handles 80 to 90 tons per day, reducing the sulphur present to 0.6 per cent, about four-tenths of the copper present being soluble in water. It was at first proposed to add salt upon the lower hearths of the roaster in order to chloridize the silver, of which a little more than one-half ounce per ton of material treated is present. Experiment demonstrated, however, that this led to the volatilizing of a good deal of the copper as chloride, and that by simply roasting in the ordinary way a better recovery was made of the copper, while the silver could be recovered by the use of a strong salt solution produced by spreading a layer of salt over the leached calcine just before the addition of the wash water. In this way over 70 per cent of the silver can be recovered at a less working cost, corresponding to a greater operating profit as compared with attempting to secure a higher recovery. It is expected that regular operation will yield a copper recovery of 85 per cent and a silver recovery of 75 per cent, corresponding to 12 pounds of copper and four-tenths of an ounce of silver per ton treated. The copper will be precipitated upon scrap iron, which also brings down the silver.

It must not be forgotten that at the three plants mentioned no attempt is made to treat slime. At Utah and Chile, crushing will be so managed as to guard against the production of slime, while at Anaconda the slime tailing is treated, as in present practice, by briquetting and adding to the blast-furnace charge. Attempts to mix in even a small proportion of slime with the sand tailing lead to great difficulty in leaching. At the Butte-Duluth, only sand is as yet being treated by the process there employed. It is evident that in copper hydrometallurgy, as in cyanide practice, the extraction of metal from slime will require careful and long experiment to develop the technique, as well as the apparatus necessary for its successful performance.

Mining as a Profession, Including First Stages of Metallurgy

By HENNEN JENNINGS

*To consider man without the earliest primitive contributions of the miner and metallurgist takes us back to savagery. Man's greatest endowment is his wonderful and crafty brain cells with their latent powers of development, which have shown him the necessity of supplementing his own strength by outside aids, and then gradually and persistently obtaining the materials for his needs and fashioning them into tools of power, and finally incorporating and making them a veritable part of his being.

His first great advances were the commanding of fire, the use of stone implements, then wooden bow and arrow. By these he worked himself into the stone age, but was still brutal, weak, and with little historical recording power. It was not until he delved below the surface of the earth for materials that he was able to fashion the sword, spear, fire arms, protective armor, plow, hoe, pruning-hook, pitchfork, scythe, tires, axe, saw, plane, etc. It was only with metal tools that great agricultural development began and it only reached its present magnitude when further supported by the metals in the form of railroads, steam vessels, harvesting machinery, etc.

Basic Industries

Mining and agriculture are the only basic productive pursuits of man, and they are both fostered each by the other, and both dependent on mother earth. The one skims her surface, the other goes deeper. Agriculture furnishes man with food for existence, but mining gives him the materials for power, art, and civilization. Without metals the scientists' tools for experimentation and determination would not be possible, nor the great diffusion of knowledge and thought by means of the printing press, photographic appliances, telegraph, cable, and the telephone.

Nothing can more forcibly illustrate the might of man as given him by the metals than the modern battleship. What could all the war vessels of history, up to 20 years ago, do against one modern battleship adequately supplied with ammunition, if they were drawn up in open battle array? Could not this one ship, by its superior speed, gun-power, and armor, annihilate at will the whole fleets of history, even if commanded by Vikings, Nelsons, and Farraguts? Is not the control of sea power the cardinal factor in war, and thus has not modern man become a war god indeed by means of his engineering genius?

In contrast to the bewildering might of the battleship's guns, with their 1400 lb. weight, and 2600 ft. per second velocity arguments, the metals have given

man fingers so delicate, untiring, and accurate that they can work and control threads so fine that fleecy muslins and laces grow in abundance under their touch.

Statistics

Let us now deal with mining on a solid and broad statistical basis, attempting afterward to clothe the dry bones of statistics with further meaning.

In this brief sketch it is not possible to incorporate the statistics and results achieved in mining in all countries. What is selected, it is hoped will be considered typical for all countries, and instructive to all interested in mining in a big way.

Great Britain produced more coal than all countries of the world put together until 1871, and more iron until 1885. The British Empire now produces 60% of the world's gold. It was only in 1899 that the United States surpassed Great Britain in coal output, and in 1897 took the decided lead in iron.

Germany's production of iron exceeded that of Great Britain in 1905, and it now mines about the same amount of coal. To Germany must be accorded priority in mining literature and technical training, as evidenced by the publication of 'Agricola De Re Metallica'* in 1556. The Freiberg and Berlin technical schools were founded in the 18th century. The first English-speaking school of mines was that of the Royal School of Mines, London, founded in 1853. Although having but a small output of graduates per year, it has been distinguished for the scientific eminence of its professors and the loyalty and ability of its graduates.

World's Mineral Production

The world's mineral production for 1912 shows that the United States produced 20% of the gold, 39% of the coal, 63% of the petroleum, 41% of the iron, 55% of the copper, and over 30% of the lead and zinc, which gives it an undisputed lead of any one country. The statistics of the United States are thus most representative, and, as the most available to the speaker, they will be extensively used. Difficulty of obtaining reliable, comprehensive mining statistics increases immensely as one goes back into the past, but, on the other hand, there is less and less to record. It will be typical and instructive to examine the last official tabular statement of mineral products of the United States, as given by the Geological Survey for calendar years 1903-1912.

In the 32-year summary of the products, it is found that the production of the metals has increased from

*Published in advance by courtesy of the *School of Mines Quarterly*.

*Translated from the Latin into English by Herbert Clark Hoover and Lou Hoover, 1912.

\$186,000,000 to \$867,000,000, or 475%; the non-metals from \$175,000,000 to \$1,376,000,000, or 775 per cent.

Analysing the 10-year statement, it is found that there are 71 mineral products tabulated, all showing material yearly increases in production. Note especially the great and striking increase in the production of aluminum, mirroring, as it does, the successful metallurgical obtainment of a highly useful metal from abundantly distributed clay compounds. The increase in cement records the great growth of modern concrete construction. The output of sulphur in various forms indicates the sulphuric acid consumption, and thus gauges the growth of the chemical and industrial arts. The phosphate rock showing points to the ever increas-

mineral products for the United States. The prices per unit for the products are estimated at pit's mouth and are extended farther into the past. It further shows the growth of the whole population of the country since 1800; the number of men engaged in mining since 1850; the increase in railway mileage since 1840; also the growth of deposits in all reporting banks in the United States since 1867.

From the world's diagram it can be calculated for period under review, that the last 15 years' production of coal has been equivalent to the 97 previous years. That the last 8 years' production of petroleum has been greater than all previous years in history. That the last 12 years' production of iron was equivalent to the 100 previous years. That the last 11 years' production of copper was equivalent to the 101 previous years. That the last 17 years' production of gold was equivalent to the 95 previous years.

In the same way the last years' production for the

ing helping hand mining is extending to agriculture.

Out of the total valuation of \$2,224,000,000 for all the products from the United States, coal, petroleum, iron, copper, and gold were estimated at \$1,579,000,000, or 70%. These metals are so representative and vital that a just and comprehensive idea of the growth of mining, metallurgy, and engineering can be obtained by following their production. This, in a broad way, can be best done by sketch diagrams, large units of products being plotted to small scale.

*Diagram No. 1 shows the yearly production for the world, all countries included, of coal, petroleum, iron, copper, and gold from 1800 to 1912, and also gives the average London price for the units of these products back to 1873.

*Diagram No. 2 gives a similar showing of the same

*Mr. E. W. Parker, of the United States Geological Survey, extended effective and kind aid in the obtainment of the data for the mineral production. The data for the bank deposit curve was taken from the National Monetary Commission Report. The growth of population, miners, and railways are as given by United States census returns. The discovery of gold

United States will be found to balance all the previous years. For coal, the last 11 years; petroleum, the last 8 years; iron, the last 11 years; copper, the last 9 years; and gold, the last 22 years.

Magnitude of Mining

The wonderful modernness of big mining can also be further realized by attempting to obtain any statistics of production previous to 1800, such attempts leading one to the belief that all the coal, iron, and copper mined in all ages, for the whole world, prior to this date would not amount to the probable world's production for the years 1913 and 1914. Petroleum practically came into use only in 1860. It is estimated that the total production of gold from 1493 to 1800 was \$2,371,000,000 whereas from 1800 to 1912 it amounted to \$12,411,000,000.

It is seen that the selling prices of the mineral products at the London market and locality of output in

in California and Australia caused the great jump of the gold curve 1850-1865.

the United States were higher in the early years than the later ones. Thus the present great increase in cost of living is not to be found in the unit advances of the products of the mineral kingdom. It is interesting to know that the cost per ton for coal at pit's mouth in the United States is less than the cost per ton at pit's mouth in Great Britain.

Fuels—Coal and Petroleum

Fuels are most necessary for the metallurgy of the metals and are storehouses of energy. In 1912 the United States coal production was 534,000,000 tons, and petroleum 222,000,000 barrels. They both have great industrial value besides that of fuel, but our time will not permit of this consideration, or include natural gas in our estimates. To obtain some idea of the meaning of the force locked up in these enormous amounts of fuel, it is only necessary to calculate the work that would be given out if they were all (and which was largely the case) used for the production of steam-power, with at best not more than 15% of the latent power utilized.

Petroleum in the form of gasoline can be more efficiently used for power in the automobile and other forms of the gasoline engine, but reducing the 222,000,000 barrels to the coal equivalent of 51,000,000 tons, we would have the steam force of 585,000,000 tons of coal. Dividing this among 100,000,000 inhabitants would give 5.85 tons per capita. The equivalent of 5.85 tons in horse-power can be taken at 5850 horse-power hours, or as much energy as would be given out at pumping by a man in 9850 days, or 27 years. This coal could thus give out force by the steam-engine equal to a population of 2,700,000,000* strong men.

The life of coal and petroleum deposits has been variously estimated. Should the increment of increase in yearly production continue, the known fields of petroleum would probably be exhausted within a comparatively few years, and coal in one or two centuries, but should the present population and per capita consumption not greatly increase, the coalfields might last one or two thousand years, and the petroleum possibly a hundred.

Should fuel outputs continue progressively to increase, greater and greater numbers of the population must be employed in their mining; also a greater and greater percentage of people would be required to generate, control, distribute, and pay for the power manufactured. There must be, therefore, a point where the population becomes saturated with power and can use or pay for no more per capita. The less the workers, the less the number of hours they work, the less their efficiency, the sooner will this saturation be reached. This may still be a long way off, and may be greatly influenced by future invention, but approach is steadily being made toward it. It will be the determining factor for final outputs.

*Kent estimates man's work pumping 10 hr. per day = 1,188,000 ft. lb. 2 lb. coal taken for hp. hour = 1,980,000 ft. lb.

Useful Metals—Iron and Copper

Under iron is included steel. The steel is often directly made from iron ores and estimated as pig iron. This group includes tin, lead, zinc, quicksilver, aluminum, platinum, etc., but it is not feasible to deal with them all, and iron and copper in themselves are the mainstays and the most useful of the metals.

Metals in useful form can not be readily obtained from their ores without fuel. On the other hand, the fuels can not be chained to great service without the use of the metals—for example, in the form of steam-power. The metals can be made use of independently of the fuels in manufacturing power from falling water, rising tides, vigorous breezes, and possibly burning sun. They are essential, as has been explained, for all manner of necessary tools and implements. Of late copper, through dynamos and motors, has revolutionized the production and flexible use of power.

In considering the importance of the yearly production of those metals, it must be taken into consideration that they are not destroyed when once used, as is the case in the fuel group. They are put into machinery and tools that may last for many years, and are again given new life by fire and fashioned into other tools and machinery whenever the economic conditions justify such regeneration.

On the other hand, the metals, including the precious, are far less abundantly distributed than the fuels, and their more speedy exhaustion is a matter far more imminent and serious. The utmost parts of the world have been searched for gold, silver, copper, platinum, tin, and nickel. Naturally the deposits of these metals that are in most striking evidence and abundance have already been found. In the future there will be less cream to skim, and a more thorough and costly exploration and prospecting resorted to. The exhaustion, even under the present basis of output, of the metals is not so very far afield, and their discovery, conservation, and right working becomes more and more a matter of importance and difficulty, and should be given serious and broad public consideration.

Precious Metals—Gold

Under this group silver is usually included, but gold alone will be discussed. Gold has a limited use in the arts, also as an ornament, but its chief value is its concentrated and convenient standard of barter. Whether this started on a basis of caprice or custom, it is now firmly established on a labor basis of value. Gold coins can be considered storage cells of human energy that give out a strong and genial current of trade confidence, circulating and binding trade, and bringing together industries of different peoples, in different lands, with different customs. The vitality and value of these cells is the labor elements poured into them—in other words, the human difficulty of their obtaining.

The history of gold mining is almost uncanny in that it has for ages shown success and failure so hand in

hand that it has taken a full labor equivalent to obtain the gold unit.

In the greatest of all gold mines in history, those of the Transvaal, there are employed nearly 200,000 black and 26,000 white men to get out a yearly return of \$180,000,000, and this does not include the labor expended on the supplies and machinery shipped to the mines. It has been found that nearly three-fourths of the output, even of the successfully producing mines, has been required to meet the current working expenses.

The curves on the diagrams show that the other mineral productions have increased correspondingly with gold. Gold may be cheapened by future phenomenal discovery but until then it rests on a firm foundation and supports vast structures of credit, which have

five of the technical societies of the United States, which, in 1912, totalled about 24,000.

The diagrams show the sudden and sympathetic growth of membership of the societies compared to production of the minerals and is especially noticeable for the mechanical and electrical engineers when compared with the production of iron and copper.

The diversity of the mining and metallurgical societies can be accounted for by the different duties and responsibilities of the coal, iron, and metalliferous mining engineers, the latter being often called upon to do their work in distant lands far from professional aid or corporate guidance. The splitting up of these societies in Great Britain makes the membership and production curves of the minerals less in parallel than is actually the case.

Upon diagram No. 4 the enrollment curve of students in all branches of engineering at Columbia is given and again shows marked accord with the growth of

grown in magnitude even more rapidly than the gold output, as is seen by the bank deposit curve on diagram No. 2. The deposits in 1867 were less than \$1,000,000,000, and are now over \$17,000,000,000.

It may seem a waste of human energy to pay so much in labor for the circulation of financial confidence, but confidence is necessary and vital, and easily disturbed. When nations can have sufficient confidence to do away with their costly war equipments of metal, they will probably also be able to do away with the gold metal standard. There does not, however, seem to be any immediate hope of their doing either, and the limitation of gold mining may be found rather in its increasing scarcity and difficulty of obtainment, as the present goldfields seem to have about attained their zenith.

Engineering Societies and Schools

*Diagram No. 3 shows the birth and growth in membership of the six main technical engineering societies of Great Britain, which, in 1912, totalled about 30,000.

*Diagram No. 4 shows the growth in membership of

mineral production. The Columbia School of Mines, the oldest and most renowned in the United States, is also a part of one of the largest and most important schools of applied science; although it is only one of the many in the United States. The Bureau of Education (Department of the Interior) in 1911 gave in round figures the total enrollment for the technical students in all schools, colleges, and universities of the United States, as follows:

| | |
|----------------------------|-------|
| Civil engineers | 9,000 |
| Electrical engineers | 6,100 |
| Mechanical engineers | 7,000 |
| Mining engineers | 2,300 |

or a total of 24,000. Note how this is in tune with the membership of the engineering societies of the United States.

The number of technically trained men required by the mining industry has been most ably and interestingly dealt with by Professor Christy of the University of California in 1893, and President McNair of the Michigan University in 1905. They both show that al-

*The curves of growth of Great Britain societies have been prepared by Mr. Edgar P. Rathbone. Those for the United States are as given by the American Society of Mechanical

Engineers, January 1914. The Columbia School of Mines curve has been prepared by Dean Goetze.

though the number required was not then large in the aggregate, it was in ratio to the production and number of men engaged in mining.

Upon diagram No. 2, it will be noted that the growth of railway mileage is rather in parallelism with the growth of mineral products than that of the population of the United States. The relation of railroad transportation to mining is most marked and important, and was the subject of an able address given by Dr. Douglas to the graduating class of your School of Applied Science in 1906. He then showed that the production of iron and the building of railroads had kept step in the United States since 1840. He also showed by tabular statements that from 45 to 58% of the traffic movement of the United States was in connection with products of mines. Later statistics only confirm this statement, and would indicate an even higher proportion.

Discussion

The object of the diagrams has been to place before you facts in general perspective, rather than accurate detail, and by using tracings so that the diagrams can be placed one above the other, the accord of all the growths shown can be better appreciated than by words. It is certainly interesting to see the great part that is being played by mineral products in the affairs of the world.

In a broad way, let us now try and read some of the meanings and lessons that the foregoing diagrams, statistics, and statements seem to give us. It would appear that mining and metallurgy, after dwelling in a lowland of drowsy accomplishment for centuries, then pioneered and stimulated by great gold discoveries, sprung into gigantic activity, and by leaps and bounds, all within the life of this School of Mines.

This has been brought about by the growth of knowledge through science, invention, and engineering, which first made clear the possibility, and finally the way, of the manufacture of power on a scale never dreamt of before, and thus giving man an almost Aladdin's power of summoning and enchaining a gigantic retinue of obedient impersonal servitors.

All branches of engineering have eagerly and ably contributed to this accomplishment, but they could never even have started without the miner. Do not the force currents that have been generated from mining products, and controlled and set in circulation by engineering skill, supplement or supplant manual work and thus constitute the basic cause of the growth and might of modern wealth? Look at the indicator gauge of bank deposits, and thus bank circulation!

In contemplating this flow of force, are we not impressed with the analogy between the circulation of blood in our bodies, and the wealth currents in trade? Does not a sudden halt and stoppage mean paralysis or death in either case, for circulation is vital to trade as to life?

The arteries of commerce require veins for distribution and return as does the body. All parts of the body,

even the brain, have limited absorbing power and must return the remainder to the moving blood currents, and thus the richest of men have but small individual wealth-absorbing power and must let the rest of the current go through them. They can be a great artery of flow, but not a terminal reservoir.

It is quite natural that bewilderment and unrest should follow the sudden might of this ever-growing flood of power summoned from the mineral kingdom—more time, more patience, and more industry are required to understand and govern it aright. Force uncontrolled or misunderstood is dangerous in proportion to its magnitude, but as it is harnessed and controlled by a serene and equitable understanding, so must it benefit and redound to the service and advancement of man.

To obtain the great production of minerals for the manufacture of force, and then its various useful transformations, has required not only the creation of huge and complex manufacturing tools, but also new great implements of finance, and thus the growth of the Limited Liability Corporation and Stock Exchange has been in sympathy with the mineral production. The precipitous curves in the diagrams all show that there must have been all manner and forms of human stimulus to have made the showings possible.

Over-eagerness to drink of the force fountains produced over-promotion and over-competition, which demanded in turn remorseless skimming of cream resources without any reckoning of the future, as is shown by the wasteful methods of mining and extravagant use of fuels, and the intensive, remorseless use of labor, both of hand and brain.

To obtain the effective dollar, for legitimate enterprise, by means of the stock exchange, many are circulated in demoralizing gambling. The capriciousness of ore deposits is an acknowledged fact and problem in mining, and the wise balancing and weighing of probabilities and possibilities, so as to make good guesses, based on slender foundations, is the great and final accomplishment of the successful mining engineer.

Hazards of Mining

Mining is not an unreasonably hazardous business if its capriciousness is recognized and if initial payments for unproved chances are not made too great, and expenditures for equipment are not undertaken upon insufficient foundations, and risks are averaged by spreading them. Advantage has been taken by company promoters and manipulators of the legitimate uncertainties of mining, to excuse the wildest mining ventures and the exploitation of stock certificates, rather than ore deposits. This has handicapped legitimate mining by making it difficult to obtain promising initial prospects at sane prices for purposes of honest test. It also tends to belittle the good name of a basic industry upon which modern civilization rests.

The fallacy of the belief that mining can only thrive through the stock exchange is known to those who have

been connected with big mining affairs, and have seen that successful enterprises have been initiated and carried through dark days of slow development and depression, by people who have knowledge, courage, and money to back their convictions. The stock exchange shows its greatest activity when least needed, that is, in inflating success and exaggerating failure. The transactions of the mining and other engineering societies, as well as the honest and high-class publications of the leading technical press, are giving such educational light that it is hoped and believed that mining exploitation by the stock exchange is very much on the wane.

To be fair to the stock exchange, it has often caused successful mines to be developed, which otherwise would not be worked, but the profession with which I am dealing, has not the stock exchange as its guiding star. It must nevertheless be acknowledged and understood that mining is not undertaken for making statistical showings, or for philanthropic purposes. Its fundamental idea is to make money for those who undertake it, and the success of the mining administrator or engineer is largely gauged by the return of profits he can show.

After the protection of the lives of his workmen, rightly the engineer's first duty is loyalty to the owners of the enterprise that employs him. The owners, who put up only their own money, have a right to decide to what extent they make their business and engineering information public. But, when a limited liability corporation is formed, the case is entirely different, for this means the partnership becomes unlimited, and, as all partners have right to knowledge, the engineer's loyalty to his owners changes from the few to the many.

In writing reports for private owners, the engineer should protect himself and the public by placing before himself, and then on record, all facts obtainable in any way bearing on the problem, and then, and only then, write his conclusions, submitting the report to his principals upon condition that, if made public, it will be given in its entirety, or as edited by himself. The essence of engineering ethics is to obtain full truth, first for himself, then to give it in full to his employer. If this is done with industry and frankness, all the other ethical rules with which our engineering associations are struggling, will be but corollaries.

The secrets of mining should be more and more confined to those given by nature. Mining titles and laws should be established with more certainty, so the most generous and honest are not handicapped or preyed upon, by the most shady and dishonest.

Educational

The subject of the relationship and preparation of students for the mining industry has been a fruitful theme of papers in transactions, and addresses to colleges and universities, and it is not necessary for me to emphasize its importance.

The interlocking and parallelism of the educational

needs of different branches of the engineering profession were clearly recognized and set forth by Professor Monroe ten years ago, who, at the same time, pointed out the necessity of a greater diversity of knowledge for the mining student than for any other branch of engineering. The decision of this University to demand from all applicants for engineering degrees a sound foundation of general culture before specializing, and equal to that preliminarily required in any other profession, is only in keeping with what I have endeavored to show to be the great responsibilities and powers, which have of late years been demanded of mining and other engineers.

Pioneers in Mining

It is obvious that in the early days of big mining the accomplishment and numbers of technically trained men did not equal or fit the demand, and that many forceful, talented, energetic men must have risen from the ranks to leadership. They were the first in the saddle, and, naturally, did not always see the full necessities of training, without which they themselves had succeeded. But assuming equal individual ability, the wastefulness of acquiring knowledge by only personal experience, and not by making use of the stored experience of others, must tell against the merely practically trained man.

The great self-made mining men of the past must be recognized and revered, both in the technical societies and schools, for they have been the pioneers and makers of history. Though in time a degree from an engineering school may, and should be, regarded as a first necessity, the demand for it should not be made retroactive.

The student of the future should only regard his degree as the trainer's certificate of efficiency and soundness, for a race and struggle, still ahead of him. Practice, as well as theory, is essential. The danger of only theory in formative years, even for the diligent student, is that the slowness of results and drudgery of practice becomes distasteful, and commercial success not so palatable or satisfying as to those who work their way up from the ranks.

Your school of summer practical training, giving students a preliminary contact with actual work, is excellent so far as it goes, and its success has been shown by how greatly it has been copied. It is to be hoped that even greater demand will be made by the schools for early practical experience, and to be rewarded by a post-graduate degree. Students who have worked for wages and have obtained approbation of employers, and have been thrown in intimate contact at the formative time of life with the ordinary wage earner, on equal terms, have obtained an experience most desirable and most necessary for the engineer.

In these days of impersonal corporation ownership, the closest and most intelligent link between capital and labor is that of the engineer. To be of the greatest use he should know the life, ambitions, and viewpoints

of each, and bring wisdom and sympathy to both sides, in the bitter and dangerous struggle that is now going on between those, so intimately bound and tied together, that the paralysis or death of one, means the same for the other. Such experience can only be advantageously obtained for the engineer, before he has assumed responsibility of leadership in dealing with labor.

It is the right labor viewpoint and basic principles of business economy that should be more and more given to mining and other engineering students. Engineering training should not simply be limited to those certain to practice it—it should be used and looked upon as a gateway to leadership in all great business enterprises, for it is fundamental in its training, and teaches the necessity for accuracy, the search of truth, probing error, and the frank acknowledgment of limitations. The gigantic forces set so recently in circulation by the miner and engineer must not only be better understood by the professional man, but also by all leaders of affairs. What is the use of a perfect engineering report, if but hazily and imperfectly understood by those who have to use it?

As to general culture, do the only dumb-bell mental drills of the past, which might be well adapted for a different set of knowledge and economic conditions, hold good when the new economic conditions have revolutionized sciences, wealth, and opportunities of education?

Is the average attitude of the students in our great centres of learning, who so often place athletics and college social success above scholarship, indicative of the satisfying character of knowledge supplied? Never before in the history of the world has there been more necessity for the clearness of vision and honesty of thought than now, when great overwhelming material force is flooding the world. False hopes, false ideals, false education, and revolutionary socialism, which only sees the wrongs and misery of the present, and the cure by annihilation of all good with evil, must be met by sane and strong training of future leaders, and from what schools can we hope to better obtain help than those of engineering?

Conclusion

In conclusion, it will be necessary to consider more closely mining as a profession, in which, of course, is included the early stages of metallurgy. The mining engineer must have some sound general knowledge of all other branches of engineering, inasmuch as in the equipment and running of great mines and metallurgical plants he must make use of the training of engineers in almost all the other branches, and to obtain from them their best and hold their respect, it is necessary for him at least to appreciate the foundations of their specialties, intelligently to confer with them, and decide upon merits, rather than dicta.

In addition, he must have special knowledge and training in all pertaining to the discovery, working, and

valuation of ore deposits. He must have also sound business experience and judgment to gauge the payability of new ventures, and this in turn requires that he should have had, in some period of his career, a successful experience in management, requiring a knowledge of accounts and faculty of handling men. In distant lands he must have general information of many kinds, and linguistic attainment.

The legitimate uncertainties of mining throw peculiar temptations in his path, as these can be twisted to excuse failures of indolence and unfitness, and also be used as narcotics to conscience when temptation to dishonesty presents itself.

His work, especially in metalliferous mining, is often far afield from the observance and guidance of owners or directors, and his work is not of a character that erects lasting monuments or stimulates either admiration or criticism. Thus character, industry, and tact are even greater requisites for true success than brilliancy of intellect.

Right character building, begun in such an institution as this, is the greatest benefit it can confer. This idea has been most fittingly expressed by one of its most beloved character builders, Professor Kemp, in University quarterly, December 1913.*

It must be a great satisfaction to this University and other kindred training schools for the engineer, to see how the great majority of the students have responded to their character builders, inasmuch as the records of this, and other high-class institutions, show that very few of their graduates have succumbed to gross financial temptation.

Mining brings in touch engineers of different lands with different training, in such a way that general recognition and good fellowship are unstintingly extended (as the speaker must gratefully acknowledge) irrespective of nationality.

Mining as a profession requires varied knowledge and gives scope, ability, and character, and is a profession befitting the true gentleman as well as the adventurous strong man. It affords absorbing and interesting work, and, being basic and productive, extends opportunity for clean money prizes.

Each branch of engineering is based upon metallic foundations; each is dependent upon the other, and none could have reached its present magnitude without the others, but the miner gives to all the other branches the materials that knit them together, in common bond of usefulness making them effective in the art of "Directing the great sources of power in nature for the use and convenience of man."

*Many, as I have mentioned, follow courses of study in the natural sciences from interest in the subjects, but the student can not do so without reflex influence upon himself. He is, for example, obliged by the very nature of the pursuit to be accurate, precise, and orderly in thinking. False observations, careless records, or confusion of thought bring no results. Clearness and remorseless regard for truth must be all absorbing."

THE SHAFT OF THE RAINBOW LODE DEVELOPMENT COMPANY.

The Rainbow Lode Shaft

By E. C. REEDER

The northeastern part of the Butte, Montana, mining district is of increasing interest to mining men. The advent of the Butte and Superior companies and their phenomenal success in making a bonanza zinc mine out of the old Black Rock claim, which was originally supposed to be valuable only for its silver ores and the pockets of copper ores occurring occasionally, has led to extensive development on adjacent proper-

ties to prevent the alignment of the shaft becoming impaired through crushing and movement of the wall rocks adjacent to the vein which always follows the mining of the orebodies.

The shaft itself is practically square in section and is divided into three compartments consisting of two skipways and space for a large cage for men, timbers, supplies, etc. (Fig. 1). This type of shaft construction is a decided innovation for the Butte district, where the common type of shaft consists of three compartments arranged side by side, as in Fig. 2, which represents Granite Mountain shaft. On this account the Rainbow shaft is unusual, and this form of construction is being watched with great interest by Butte mining men. This type of shaft has been bor-

FIG. 1. RAINBOW SHAFT.

FIG. 2. GRANITE MOUNTAIN SHAFT.

ties in this vicinity. One of these newer properties is the Rainbow Lode Development Co., which is controlled by interests affiliated with the North Butte Mining Co. The property of the Rainbow company comprises an extensive acreage which is traversed by the outcrop of the Rainbow lode, which is extensively opened farther west in the so-called silver district, and a number of mines are situated on this lode. The name of this lode is taken from the rainbow-like curve its outcrop makes.

The Rainbow lode shaft is situated in the foot-wall side of the lode and at a sufficient distance from it

rowed from the Lake Superior iron country, where it is a common form of construction.

The Rainbow shaft is also the first shaft in Butte to be sunk wholly by electric power. Other shafts in Butte have the benefit of electric power for various purposes such as compressors, haulage, etc., but the entire plant at the Rainbow shaft is operated by motors.

The shaft was sunk from surface to a depth of about 800 ft., using a 75-hp. single-drum electric hoist, and it is the intention to go to the 2000-ft. level before doing a great deal of lateral development. As the

small hoist was too slow and too light to attempt its use for greater depths, a more powerful machine was ordered from the Lidgerwood Manufacturing Co. and was installed last December.

The large hoist is shown in Fig. 3, and consists of two separate drums arranged side by side and driven through friction clutches by gearing to an induction motor. Each drum is 84 in. diameter by 50-in. face, grooved to hold 2000 ft. of 1-in. rope in two layers. Instead of mounting the clutches on the drum-shaft as is the usual construction, they are attached to the driving pinion. With this construction each drum is keyed to its own shaft and has its own separate gear. The advantages of this construction are numerous. The hoist consists of practically two units and can be operated indefinitely as a single-drum machine by merely disconnecting the driving shaft. When hoisting with only one drum and holding the other drum on the brake, there are no drum bushings to wear oval, due to a heavy drum resting on a revolving shaft. The clutches, being attached to the pinion, are small in diameter and proportionately light, and the motor is not required to accelerate such heavy drums as would otherwise be the case. They being small can easily be operated by hand, and complicated auxiliaries are not needed. Repairs and adjustments are easily made. The clutches themselves are of a new type especially developed for this service and consist essentially of two cone-shaped friction surfaces of hard maple with cork inserts, drawn together by a series of toggles and gripping between them a steel friction ring.

The cones are mounted on a steel spider keyed to the driving shaft, and the friction ring is carried by a steel bell or drum-shaped spider, which has a sleeve on one end upon which is mounted the pinion for driving the drum. The bell or drum is fitted with heavy bronze bushings and the entire friction device is enclosed in a case which can easily be opened for inspection and oiling.

Each drum is equipped with a heavy post brake lined with wood blocks. The brake flange on the

drums, instead of being cylindrical, is V-shaped, and the brake-blocks are shaped to correspond. This gives an especially powerful brake action with very little effort on the part of the operator.

There are two gear reductions, all the gears being of steel with cut herringbone teeth made by the Falk company, and they run smoothly and quietly. They are enclosed in a gear case and run in oil, while the drum gears are covered with channel-shaped guard bands which cover the face and ends of the gear teeth.

This hoist further departs from tradition in that the bedplate or frames are made of structural steel instead of cast iron. The box girders comprising the side frames are sunk into the concrete foundation, so that the base of the pillow-blocks are on the floor line. This securely ties the machinery and foundation together into one compact unit.

The motor is 300 hp., General Electric manufacture, 580 r.p.m., of the wound rotor or slip-ring type, and operates on alternating current, three phase, 60 cycles, 2200 volts. The control is the latest type of magnetically operated contactor with a master controller. The primary circuit is controlled by two contactors, each with three poles, and the switches are air-brake with magnetic blow-outs and slate deflectors. One contactor is provided for each direction of rotation. The secondary of the motor is controlled by contactors which are automatically controlled by current relays and interlocks. The secondary panel is arranged for three points hand control in either direction, with acceleration automatically taken care of at a predetermined rate by the current relays. A small transformer reduces the voltage for the magnets and master controller to 220 volts, so that the high voltage is not passed through the operator's controller.

By the use of high voltage the cost of transformers and the loss through them are saved, and also the effect of drop in voltage is felt much less on the motor than if the usual pressure of 440 volts were used. The secondary resistance is of the usual iron grid type. Dial indicators connected to each drum show the position of the cages in the shaft.

FIG. 3. TWO VIEWS OF RAINBOW HOISTING EQUIPMENT.

Replacement Orebodies at the Gray Eagle Mine

By FRED H. DAKIN, JR.

The Siskiyou range of mountains extends in a westerly direction, along the boundary line between the states of California and Oregon, to within 45 miles of the coast, and thence in a southerly direction 75 miles, where it joins the Coast range. The Gray Eagle mine is situated, at an elevation of 3000 ft. above sea-level, in the angle thus formed. It lies five miles north of the Klamath river, and ten miles south of the summit of the range and the Oregon boundary, in the northwest corner of Siskiyou county, California. The general elevation of the summit of the range is 5000 ft. above sea-level, with several passes of about 4000 ft. and some higher peaks at an altitude of from 7000 to 9000 ft.

The Siskiyou range consists largely of intrusive rocks, mainly granodiorite, gabbro, and serpentine.

The Gray Eagle mine is situated in this area of schists, also several undeveloped prospects. The third series of schists is 10 miles south of the town of Happy Camp and covers an area of 20 square miles. These schists appear to be igneous rocks and are in conformity with dikes of porphyry and serpentine, which are partly schistose.

The Gray Eagle mine was held under option and purchased by John B. Farish, and was developed under my management. It consists of 14 patented claims, and is situated in the Happy Camp area of schists, as stated above, being six miles north of the town of that name. The lode consists of iron and copper sulphides, largely pyrite, marcasite, and chalcopyrite, in the schist formation. The outcrop is known to be at least 1500 ft. long on the strike, and its width is from 30 to 80 ft. The strike is northwest. Part of the lode is in an anticlinal position, but the greater part has a dip of 27° to the northeast. The lode is entirely in the schist formation and conforms with the schistosity in strike and dip. The only rocks other than the schists are a few acid dikes, about one foot in width, which cut across the schist and lodes in various directions. These dikes have no effect on the grade of the ore and do not appreciably alter the deposit. The lode has no walls; the proportion of pyrite in the formation decreasing from the centre across the width in both directions. The solid sulphide ore retains the schistose structure, and shows the deposit to be of the replacement type. The development work has shown several minor faults.

FIG. 1.

Three areas of schists, which appear to be largely of sedimentary origin, cover parts of the south and east slopes of the range. These schist formations contain the copper deposits that have been developed in the Siskiyou range. The schist areas also contain numerous undeveloped gossan outcrops. Copper minerals, largely chalcocite and native copper, have been found in the intrusive rocks, but none discovered up to this time are large enough or regular enough to warrant extensive development work.

One of the schist formations covers an area of 50 square miles, beginning at the Klamath river 30 miles west of the town of Hornbrook and extending in a northerly direction 15 miles across the summit of the Siskiyou range into the state of Oregon. The Blue Ledge copper mine is situated in this schist formation, also a few partly developed prospects and a number of undeveloped prospects. The second series of schists is 35 miles west of the Blue Ledge district. It is 35 square miles in area, extending in a northerly and easterly direction from the old placer mining town

Structure of the Lode

The lode is not uniform in grade across the width, but contains a persistent band of ore, as shown by Fig. 1. This orebody, as indicated by the figure, is not in the centre of the lode, but in most places has 10 ft. of low-grade pyrite lying over it and a greater width of pyrite under it. Its width varies from 6 to 20 ft. It has been exposed in various places on the strike for a distance of 500 ft., and at a depth on the dip of 600 ft., but its entire area outside of these limits has not yet been determined. It is remarkably uniform in grade. Although cross-cuts have been driven through it at a number of places, and several drifts have been driven in higher grade ore, no point has yet been found within the limits of the development where it is below a good ore grade. The percentage of copper varies from 3.5 to 8, but is more uniform than these figures seem to indicate. The orebody also contains from 50¢ to \$2 per ton in gold. The low-grade pyrite lying immediately over the ore, in a number of places, contains sufficient copper to form a lower-grade ore over a width of several feet.

This also holds true of the pyrite immediately under the ore.

The ore consists of iron and copper sulphides, a large proportion of which appears to be chalcopyrite. It contains practically no zinc or arsenic. A body of oxidized and secondary ore—small in comparison with the chalcopyrite orebody—lies under the gossan outcrop, the copper being largely in the form of chalcocite. Its average grade is about the same as that of the unaltered ore.

Owing to the fact that the chalcopyrite orebody lies relatively near the overlying limits of the lode, in a section across its width, it has been suggested that it may have been formed by secondary enrichment from the overlying pyrite. A close study of the orebody, however, shows that this cannot be the case. If the ore had originated in this way there would of necessity be stringers of ore cutting across at right angles to the dip of the lode. This condition is nowhere observable, the ore bands all being conformable with the strike and dip of the schists. There are also narrow bands of high-grade chalcopyrite in the low-grade

FIG. 2.

face under the outcrop until the dip of the lode parallel to the north slope was determined. Cross-cut adits were then driven at greater depth from the north side. In this way it was possible to open the deposit at a depth of 600 ft. on the dip by an adit 460 ft. long. The total development work amounts to between 6000 and 7000 feet.

Comparatively cheap power can be obtained by the development of hydro-electric power. This can be done at a number of places, some of which would develop much more power than the amount required. Owing to a lack of market, no hydro-electric power has yet been developed in the district except for placer mining.

There is an abundance of timber, largely fir, sugar pine, and cedar, in the district, much of which is well suited for mining purposes. Being within the limits of the Klamath national forest, it is almost entirely under government control. Much of this timber has been cruised and estimated by the Forest Service, it being generally understood that it is to be placed on the market and sold as soon as possible. The climate

FIG. 3.

pyrite body lying under the ore, many of which are as much as 50 ft. under the orebody. The ore also appears to contain no chalcocite or other secondary minerals, although this has not been definitely determined.

Taking everything into consideration, it seems probable that the low-grade pyrite body was formed first and that the orebody was formed at a subsequent time by a second replacement. The faults have occurred subsequent to the formation of the ore and have no effect upon the grade of the ore except a slight decrease close to the fault planes due to leaching.

The lode, as shown by Fig. 2 and 3, outcrops near the summit of a narrow ridge. It extends under the ridge in an anticlinal position, and then dips roughly parallel with the north slope at an angle of 27°. The strike of the lode is diagonally across the ridge. The northwest end of the outcrop, therefore, extends across the ridge and shows in a number of places on the north side as far as the bed of the creek. This condition determines the western limit of the deposit, at least to the depth of the creek. In the other direction, however, the depth of formation lying over the deposit increases greatly, and the full length in that direction is not known.

The topography above referred to was favorable for prospecting the deposit with comparatively short cross-cuts. Cross-cuts were first driven from the sur-

face also is favorable. The rainfall is heavy during the winter months, and in some seasons the snowfall is two or three feet, but the winters are not severe enough to interfere with continuous work. The district as a whole is mountainous, but there are many ranches along the Klamath river and on the tributary streams. The climate and soil are favorable for raising vegetables, fruit, and stock of all kinds. Farm products are, therefore, comparatively cheap. When the timber is removed the area of agricultural land will be largely increased. The Klamath region is at present retarded by the lack of transportation facilities, but as soon as these are supplied it will become one of the active producing districts of the state.

Mica is found in crystals ranging from small ones to those several feet across. Crystals two feet in diameter are not uncommon. The value of the mica produced in the United States in 1913 was \$436,060, North Carolina contributing \$267,913. The total value of the output in 1913 was \$104,164 greater than in 1912 and was the largest ever reported. The production of sheet mica as reported to the U. S. Geological Survey amounted to 1,700,677 lb., valued at \$353,517, compared with 845,483 lb., valued at \$282,823, in 1912. The production of scrap mica in 1913 amounted to 5322 tons valued at \$82,543, compared with 3226 tons, valued at \$49,073, in 1912.

PORT OF IQUIQUE.

The Chilean Nitrate Industry—I

By LESTER W. STRAUSS

Of the metallic and non-metallic minerals peculiar to the West Coast of South America, nitrate of soda is the most important. It forms the basis of an extensive industry in Chile and contributes 80% of that country's revenue by reason of the export duty imposed. Its uses are more far-reaching and beneficial as a re-invalidator of soil, so largely applied abroad, than to other applications in the arts, of which the manufacture of explosives is an important industry.

Beginning of the Industry

The beginning of the nitrate industry is said to date from 1809, in the province of Tarapaca, through the efforts of Tadeo Haenki; the wonderful results obtained in 1830, in the application of nitrate as a fertilizer, marks the realization of its usefulness and the active commencement of its exploitation. (As the outcome of the war of 1879, Chile came into possession of the fields which had previously been Peruvian and Bolivian territory.) From a yearly output of 22,723 quintals (46 kg. each or 101.4 lb.), in 1812, the industry had grown to 56,214,140 quintals in 1912. An appreciation of the 1912 output, although only 54,197,439 quintals was exported, is better obtained from its intrinsic value to the Chilean government as revenue—£6,323,035 (\$31,350,568*); the value of nitrate products was £22,302,956 (\$107,054,090); the export duty is 28d. (\$.56 per quintal, but at some future date—in view of increased cost of production, mainly due to scarcity of labor and the decline in grade of the material treated—this tax must be lowered and thus make available much ground now too low grade to permit working under the existing duty; which amounts to one-third of the average selling price. According to

figures submitted by the Chilean government, its income from 1891 up to 1913, a period of 22 years, was £84,296,334 (approximately \$405,000,000). The increasing consumption of nitrate has had its corresponding effect upon the yearly revenue from the export duty. These increases make the frequent loans of the Government, for railroads, harbors, and sundry essential improvements, a matter of reasonable security—with in bounds—as no recourse is had to taxation of the citizens individually. The following figures, totals from 1891 to 1912, inclusive, and the individual years 1891 and 1912, give an idea of the importance of the industry:

| Output: | 1891. | 1912. | Total. |
|----------------------|------------|------------|-------------|
| Quintals | 16,982,931 | 56,214,140 | 747,862,160 |
| Metric tons | 781,184 | 2,585,850 | 34,400,283 |
| Exported: | | | |
| Quintals | 17,158,971 | 54,197,439 | 723,813,593 |
| Metric tons | 789,281 | 2,493,082 | 33,294,094 |
| World's consumption: | | | |
| Quintals | 20,960,785 | 54,990,104 | 725,862,446 |
| Metric tons | 964,158 | 2,529,545 | 33,388,335 |

It is of interest to note that although the output and exportation have more than trebled, consumption has increased less than 2.7 fold during the 22 years; the difference is the necessary stock.

The nitrate industry is confined to the provinces of Tarapaca and Antofagasta in the northern part of Chile (between latitudes 19°30'S. to 26°S.). The latter province is the larger producer. The exporting ports, beginning at the north and proceeding southward, are Pisagua, Junin, Caleta Buena, Iquique, Tocopilla, Mejillones, Antofagasta, Caleta Coloso, and Tal-tal. Iquique is the most important port. The area of Chile is 757,366 square kilometres (292,343 square miles), of which the provinces of Tarapaca and Antofagasta comprise 46,957 (18,125 square miles) and 120,708 (46,593 square miles) square kilometres, re-

*Throughout this article, figures stated in pounds, shillings, and pence refer to English, and those in dollars refer to United States currency.

spectively; up to the present time 4604 square kilometres (1777 square miles) are controlled by the various nitrate companies (in both provinces), and 1345 square kilometres (519 square miles) additional have been explored, but not sold by the Government.

The districts are known as follows: pampa Tarapacá, ports Pisagua, Junin, Caleta Buena, and Iquique; pampa Toco, port Tocopilla; pampa Antofagasta, ports Antofagasta and Mejillones; pampa Agua Blanca, port Caleta Coloso; pampa Taltal, port Taltal.

In 1912 there were 170 *oficinas* (the local name for the nitrate treatment plants) including those in construction, of which 38.5% was Chilean controlled, followed by English (37%), and German companies (15%), the remaining 9.5% is represented by six nations. Only one American company exists, the Du Pont Nitrate Co., owned by the E. I. du Pont de Nemours Powder Co., operating in the Taltal district. It operated the Delaware oficina and exported 152,030 qq.* in 1912, equal to 0.28%. Recently interest has been taken by a new company, American Nitrate Co., at Toco in the Tocopilla district, where title to the ground has been in dispute between Bolivia and Chile. W. R. Grace & Co., of New York, through a subsidiary company—the Nitrate Agencies—represents 9 oficinas; the product is sent to the United States and England. The combined output for 1912 was 3,175,400 qq. (about 5.1 per cent).

The Nitrate Fields

The stretch of territory represented by the 6°30' of latitude (about 450 miles) concerned is a dry (rain falls during lapses of 15 to 20 years), arid country rising from 2200 to 7500 ft. above sea-level at distances varying from 14 to 20 miles in from the coast. (The oficina Alianza, in Tarapacá, is at 2300 ft. and the oficina Delaware in Taltal, is 7500 ft. above sea-level.) Between this plateau and the coast, is a range sometimes attaining a height of 5000 ft. above sea-level, which barrier rises rather abruptly from the sea and affords only occasional ports. This remarkable topography begins just at Arica, where the coast line turns from a southeast course to almost due south, as one enters Chilean waters from the north. The nitrate fields appear to occupy a north and south trend, thus paralleling the coast line, the nitrate usually lying on the western side of the *pampa* or plateau. The eastern side of the nitrate fields is flanked by the foothills of the Andes, that serve as a huge wall against the rain-bearing winds from the east thus cutting off the possibility of rainfall which would play ruinous damage with the nitrate ground. The cold Humboldt stream of the Pacific Ocean condenses the moisture of the warm western winds into mists which are rarely permitted to precipitate as rain, due to the strong evaporative powers of the sun. In the winter season these dense mists, or fogs, form rightly but are dispersed by the sun after daylight. The slight moisture thus precipitated affords life to some vegetation, but its effects on the nitrate ground is

nil. It has been stated that there is some relation between the fog and the nitrate as the latter is not found where the fog does not form but there is one known exception. The dry climate of this arid region is remarkable but extremely healthy. The days are hot, at noon, with heavy westerly winds in the afternoon and calm at sundown. The nights are cold but invigorating, and the mornings crisp. An amusing feature of the region is the electrical condition. Combing one's hair, dry, brings about a 'sparking' but pleasant sensation. The electrical phenomenon has been noted to affect surveying where compasses are employed.

The rocks of the region are essentially igneous, forming the coastal range and the Andes already referred to: northward from Agua Santa (Tarapacá) is con-

NITRATE DISTRICT OF CHILE.

siderable limestone and dolomite. The plateau between is said to consist, in part, of Jurassic rocks, covered over with much marine deposit of sand, gravel, and clay; the recent deposits are not of marine origin and the clays appear to be of volcanic origin. Over this lies stratified mud and angular pieces from the denudation of the hills; bedded in the deposition referred to is the nitrate-bearing mixture.

The origin of the nitrate has not been cleared up despite the theories advanced. It may be stated at the outset that the rocks of the surrounding country have not been considered as a possible source. There are several theories existing, but none are supported by conclusive facts.

It has been already observed that static electricity is present, which, acting on the atmosphere, would liberate oxides of nitrogen and these, in contact with

*Quintals.

the moisture of the air, would form nitric acid. The transition to nitrate of soda in the presence of sodium salts, is readily conceived. Ammonium salts, especially ammonium nitrate, are probable products from the effect of electrical discharges on air and water (that is, mist): reacting with sodium salt ammonium nitrate would be converted into nitrate of soda.

F. W. Clarke, in the 'Data of Geochemistry,' Bull. 330 of the United States Geological Survey, makes the following observations:*

Genesis of Nitrates

"Nitrates are commonly formed in soils by the oxidation of organic matter, a process in which nitrifying micro-organisms play an important part. In moist climates these salts remain in the groundwater, are consumed by growing plants, or are washed away: in arid or protected regions they accumulate to a considerable extent. Some nitrates are also derived from atmospheric sources, the acid being formed by electrical discharges and brought down by rain, but their amount is probably only a small portion of the entire product. Wherever organic matter putrefies in contact with alkaline materials, such as lime or wood ashes, nitrates are produced, a process which has been carried on, artificially, in various countries in order to supply the industrial demand for saltpeter. In sheltered places, such as caverns, calcium nitrate is often produced in large quantities, and its formation has commonly been attributed to the nitrification of bat guano. This supposition, however, may not cover all cases, for W. H. Hess claims that nitrates are uniformly distributed over cave floors in Kentucky and Indiana, even in the remote interiors of caverns where no guano exists. (These views have been disputed by H. W. Nichols who regards guano as the chief source of cave nitrates.) . . . The deposits of potassium nitrates found in Hungary are traced by C. Oehsenius to the mother liquors of sea water, their potassium chloride being first transformed to carbonate, which latter is then nitrified in the presence of organic substances. In this suggestion the hypothetical element is rather large, although it is plausibly defended. . . .

"No satisfactory explanation of the nitrate beds has been found although many theories have been proposed to account for same. C. Noellner, who assumed a marine origin for the deposits, suggested that their nitrogen might be derived from the decomposition of great masses of sea-weeds: but in this view has not been generally accepted. For example, the beds at Maricunga (Chile) are 3800 metres above sea-level, and 180 miles from the coast, and other localities present similar difficulties of distance and elevation. The plain of Tamarugal (Chile), studied by W. Newton, lies between the coast range and the Andes, 3000 ft. above the sea, and the nitrate beds have peculiarities which seem to preclude either an oceanic origin or a derivation from guano. Here, at least, bromides are absent,

and only traces of phosphates can be found. Sea water would yield the former; from guano the latter would remain. Newton regards the nitrates as originally formed by the oxidation of organic matter in alluvial soil. Tropical floods which cover the plain once in every seven or eight years, bring upon it the concentrated fertility of thousand of square miles and sweep the deposits to the landward side of the coast chain where they are mainly found. This is Newton's view, although he admits the possibility that electrically generated atmospheric nitrates may also be present. The same possibility is recognized by Semper and Blanckenhorn, but rejected by A. Muntz, who regards the electrical source as quite inadequate. Muntz accepts an organic origin for the nitrates, and argues that the calcium salt was first formed, as in the ordinary artificial process of nitrification. That compound then reacts with sodium chloride forming calcium chloride and sodium nitrate, a transformation which can be effected experimentally. The same result was also obtained later by A. Gautier, who finds in guano the source of the nitrogen. The reaction is further suggested by the facts that the Chilean nitre is always associated with salt, and that calcium chloride is found in the underground waters of the pampas. Muntz also proved, by direct experiment, that iodides in a nitrifying mixture were oxidized to iodates, and from the absence of phosphates in the nitrate beds he infers that the nitrates have been transported in solution and re-deposited at a distance from the original seat of their formation.

"C. Oehsenius, who has written voluminously on the Chilean nitrates, regards them as derived from the mother liquors of salt deposits in the Andes. These are supposed to flow downward to the plains, their chlorides being partly converted to carbonates by carbonic acid of volcanic origin. The nitrogen is brought as ammoniacal dust from guano beds upon or near the sea coast, the heavier phosphatic particles being left behind. That such dust is carried by the winds is certain: but is it carried in sufficient amounts to account for large nitrate deposits far inland? Another difficulty is suggested by Darapsky, who points out—in his work on Taltal—the comparative scarcity of carbonates in the nitrate regions. Even the waters of the pampas contain little carbonic acid, and among the mineral springs of Chile and Argentine carbonated waters are the exception rather than the rule.

Saline Water Theory

"That the nitrate beds are proximately derived from the evaporation of saline waters is beyond a doubt, but the evidence is strongly against their having a marine origin. The ultimate source of their nitrogen is a more troublesome question and remains, so far, unsolved. The weight of opinion favors a derivation from organic matter, and from this point of view Newton's explanation of the deposits is as satisfactory as any. Explanations of this order, however, are incom-

plete for they take no account of the remarkable association of boron and nitrogen. Why do borates and ammonia occur together in volcanic waters, or borates and nitrates in the deposits of both Chile and California? This fact, which has already been emphasized, is surely not without significance and it legitimizes the suspicion that the nitrates may be partly derived from volcanic sources. To be sure this is only a suspicion, but it is one which ought not to be left out of account. Hot springs are common in the desert of California and Nevada; they are also found along the volcanic Andean chain; do they contain boron and ammonia as a general rule, or only in sporadic instances? Such waters, collecting in lagoons in the presence of some organic matter and the nitrifying organisms, would yield nitrates, and the latter would be found in the dried residues. A careful examination of all hot springs existing in the vicinity of nitrate beds is needed before one can decide how much weight can be given to this volcanic hypothesis."

Of the above hypotheses the electrical theory has met with more general approval, at least to the extent of being considered probably the chief agent. It is worthy of mention that nitrate ground is readily picked out from barren ground, due to its dark appearance as compared with the latter, when inspected in the early morning before the sun's rays have driven off the moisture of the previous night's fog. This phenomenon is due to the hygroscopic property of nitrate, but is not an unfailing indication.

The composition of the *caliche* (the local name for the nitrate-bearing material) as mined varies from 18 to 65% NaNO_3 , but the general average is between 20 and 25%. When pure it is found in crystalline masses either white or yellow and rarely pink, the last two conditions being due to iodate of calcium and manganese respectively. As might be expected sodium chloride, sulphates of soda, lime, and magnesia are associated, besides 'earthy material'. Nitrates of calcium and potassium, perchlorate of potash, and iodate of soda occur in small amounts. A better idea of the composition of caliche can be obtained from the following analyses:

| | Taltal. Darapsky. | | | Antofagasta. S. H. Loram. | | | Tarapaca. Agua Santa. | | |

One of the largest nitrate producers in the province of Tarapaca is the Agua Santa Nitrate & Railway Co., which has been in operation, as a limited liability company, since 1889. Some idea of its importance may be obtained from the total output from the Agua Santa oficina, only, since 1876 (when the steam plant was put in) which is given as 35,000,000 quintals *salitre*, the name for the finished product. Within recent years the annual production of the Company has been at the rate of 1,500,000 quintals. The Company operates a narrow-gage railroad (30 in.), that taps 22 oficinas, including six of the Company proper, and handles about 6,000,000 quintals of nitrate per year. The line begins at Caleta Alta, from which point three incline planes serve the port—Caleta Buena. The railroad was built in 1891 and is at present 148 kilometres (92.5 miles) long as a main line and branches; its maximum grade is 3% (average 1%). At Huara it connects with the Pisagua branch of the Nitrates Railway, Ltd., which starts from Iquique; this line is standard gage. The Agua Santa company's oficinas are, in order of their importance: Agua Santa, Primitiva, Valparaiso, Abra, Elena, Democracia, and Irene. The last was but recently completed. The total production for 1912 was 1,492,205 quintals, of which the Agua Santa plant contributed 548,633 quintals; it stands eighth among the 99 oficinas existing in Tarapaca, and the Company ninth among 73 producers in the industry. The following descriptions of mining and leaching refer to the Agua Santa plant, but the observations made cover the general practice in the industry.

Occurrence and Composition of Caliche

In the Tarapaca fields four horizons are recognized in the exploration work. The surface material, called *chuca*, is loose and crumbly material containing porphyry boulders; this is usually less than one foot thick and on its character is based considerable importance in prospecting work—it carries little or no nitrate. Below this comes the *costra* which is similar to the *chuca* in appearance but more solid; the cementing constituents are sodium salts of which sodium nitrate often forms a considerable percentage. It runs as high as 25% NaNO_3 , but 10 to 15% is the average; its thickness varies from a few inches to 15 ft. In appearance it frequently resembles a breccia. Where high grade, that is above 14%, it is being mined. Next comes the *caliche*, or the cleanest nitrate mineral, which when pure, is found as crystalline masses either white, yellow, or rarely pink; the usual color of caliche is reddish brown. The average caliche mined varies between 18 and 65% NaNO_3 , while picked samples run up to nearly 100%; the thickness is from under an inch to 5 ft., the average would be from 1 ft. to 3 ft. The specific gravity is generally taken as 1.5 for calculation purposes (as only 75% of the mineral is considered as likely to be extracted), although the mineral is 2. The underlying (or 4th horizon) layer is known as *coba*, and consists of a brownish colored

earth mixed with sand and gravel. It contains a slight amount—never in commercial quantities—of nitrate. Below the coba is the igneous rock which is found at varying depths, and in the main valleys are marine beds.

The following analyses, given by Semper and Michels, indicate the constituents of the chuca, costra, and coba. Analyses of caliche have already been given:

| | <i>Chuca, %.</i> | <i>Coba, %.</i> |
|--------------------------|------------------|-----------------|
| Silicic acid | 46.70 | 25.05 |
| Iron oxide | 2.00 | 1.64 |
| Aluminum oxide | 12.42 | 7.96 |
| Manganese oxide | 0.45 | 0.65 |
| Calcium oxide | 9.26 | 6.82 |
| Magnesium oxide | 2.88 | 1.92 |
| Potassium | 1.02 | trace |
| Sodium | 1.99 | 19.93 |
| Sulphuric acid | 13.23 | 20.09 |
| Nitric acid | 1.14 | 2.49 |
| Carbonic acid | trace | 1.75 |
| Phosphoric acid | 0.85 | 0.17 |

| Potassium nitrate | 1.7 | ... |
| Sodium iodide | 0.1 | ... |
| Insoluble | 42.2 | 52.0 |
| Moisture | 2.6 | ... |

It appears that the costra horizon is not always present in the nitrate fields of the southern districts.

In the early days of the industry, only the high-grade caliche was exploited and considerable was lost in the mining. Present day practice is confined to closer work and selection of probable profitable ground regardless of separating caliche from costra where both can be treated commercially.

The method of exploration is systematic and resembles the sampling of gold placer ground except that drilling machines are not employed. The area controlled is divided into squares usually 100 metres to the side, and holes—begun 9 in. in diameter—are sunk with 'jumper' drills to the coba; the chuca being cleared off prior to drilling. The 'jumper' drills are of 1½ to 1½-in. steel, or iron tipped with steel and range up to 15 ft. in length. As a rule 10-ft. drills are employed. The holes are made conical in shape, the apex being on the surface. When bottomed a light charge of gun-powder (dynamite when going through hard caliche) is exploded in them and the blasted material brought to the surface. Boys are usually employed to enlarge holes in the coba below the caliche. The sample is carefully picked over, before assay, all the coba being discarded. Data are taken not only as to the thickness of the caliche, but also the character and thickness of the overlying costra and chuca. The drill holes are plotted, with their corresponding

caliche contents and thickness, from which results the extent of the nitrate area is obtained. It is usual to assume that between a hole containing commercial caliche and an adjoining barren, or low-grade hole, half of the intervening distance can be allowed to be within the profitable area (the caliche deposition is necessarily of irregular shape and distribution although continuous). The tonnage of caliche is arrived at by multiplying the cubic metres by 2. This gives metric tons. Of this figure 75% is taken as the probable amount that will be extracted in mining. Where the costra is of commercial grade, its tonnage is calculated similarly, except that only 50% is taken as extractable. The full assay values are not used to arrive at an average of the area, deductions being made for losses in treatment. These deductions vary from 30 to 40% of the assay results, depending upon the grade of the caliche and the character of same. The cost of drilling varies from 50 centavos to 2 pesos per foot (11c. to 44c.), according to the nature of the ground and depth of the hole. Churn drills, such as are employed in gold placer ground, or at the 'porphyry' mines, might do the work more rapidly if the material was not of shallow depth as a rule, and possibly cheaper, but the necessity of water, in the work, would be a serious and detrimental factor though the use of compressed air would appear feasible.

Mining Caliche

Mining the caliche consists in first putting down holes similar to the prospecting holes, but with heavier charges of black powder varying from 100 to 1000 lb., according to the nature of the ground to be opened. Dynamite is only employed to break up large blocks of caliche or for sinking shafts. The black powder is home made, from coal 'fines', refuse nitrate, and sulphur. The last was previously brought from Italy or Japan, but is now obtained from the Tacora deposits inside from Arica, Chile. The powder mixture consists of 25 lb. of coal 'fines,' 100 lb. of refuse nitrate, and 25 lb. of sulphur. The cost is about 0.33d. (1c.) per pound of powder. A charge of powder has a heaving or lifting effect, in exploding, thus tending to minimize the making of 'fines.' The blast makes little noise, only a low rumbling effect resembling an earth tremor, and is accompanied by a cloud of dust, sometimes overshadowed by brownish nitrous fumes resulting from the explosion when the powder is wet or badly mixed. Holes, from 10 to 35 ft. between centres and parallel to the working face (and usually at a distance equal the depth to the caliche ahead of it), are prepared in advance of the face and fired as occasion demands. It is sometimes found practical to lower a boy into the holes to enlarge the opening when the coba has been reached. In such holes black powder has a greater lifting effect when exploded. This method is also used for isolated or thick beds of caliche. A working face is begun by laying out a trench, dug to the top of the coba and

continuing it according to the nature and extent of the costra and caliche; the process of extraction is similar to bench mining. The chuca is cleared off and thrown as far back as possible; the costra, however, is stacked up, somewhat like a pack wall. The larger pieces are broken down with a wedged-shaped piece of iron using a 25-lb. hammer. These pack walls of costra are sent to the leaching plant whenever of commercial grade, that is above 14%. The broken caliche usually consists of pieces easily handled by one man. Where large blocks result block holing with dynamite is resorted to. The lump size (the 'fines' being disregarded) is sorted out and piled up on the costra, to be carted away to the nearest loading station. A nitrate field, after exploitation, greatly resembles a battlefield with earthworks erected minus opposing armies and accessories. Mining is done on contract, that is to say the company prepares and loads the holes after which the contractor takes matters in charge. The prices paid are 2 pesos (say 44c.) per cart load (35 quintals) for costra and up to 20 pesos (\$4.40) per cart load for 50 to 60% caliche, according to the difficulty of extraction. There is a sliding scale rate per cart load, based not on the grade of caliche but on the comparative ease of extraction, a higher rate can be afforded for the good quality when difficult to extract. The contractor is paid for his work, not the quality of the caliche.

Losses in Mining

The losses in mining caliche are said to vary from 15 to 25%; when costra is taken out for treatment the mining loss is small but the milling loss is great. To the outsider it would appear that crude methods have been employed in mining; these were begun in the commencement of the industry and custom established same as a standard. The introduction of modern methods, particularly the possibility of steam-shovels in mining, has been suggested, but the general argument against a radical change has been the irregularity of the deposits; lack of technical administration is more to the point. In few instances have technical men been put in charge of operations.

Darapsky, in his work '*Das Department Taltal*', mentions calcium nitrates existing in cavities in limestone in the province of Tarapaca. These have been exploited with underground workings to a depth of 40 ft., until non-commercial nitrate was met. The origin is due to "underground water that has passed through the nitrate region and come to rest in a land-locked depression where it evaporates." In the Salar del Carmen in Antofagasta, which, S. H. Loram states to be of the above origin, nitrate crystallizes upon the surface and is worth removing about every four or five years. It has been cited as a case where nitrate grows and has led to a confusion as to its origin.

The caliche is loaded into two-wheeled carts, usually hauled by three mules, at a cost of 30 centavos (6.6c.) per cart. Sometimes sorting over is done, prior to loading, at a cost of 1 peso (22c.) per cart load. The

length of haul is generally short, and as a rule over light grades. In general, no attempt is made to load from the ground direct into railroad cars, eliminating cart haul; also, a cart driver never walks alongside but is mounted on the left wheeler. As a rule a man can mine and load from one to two carts per day depending on conditions as well as the individual. Where the ground is mined under difficulties the day's pay is the basis employed.

At the loading station the cart is dumped, the contents falling on an incline platform loading directly to

NITRATE FIELD. A, UNLOADING STATION FOR CARTS; R, RAILROAD LINE; C, CART ROAD.

steel side-discharge, hopper-bottom railroad cars, which hold 7 tons each; these are made up in trains, of six to eight, and hauled by (21-ton) locomotives to the *maquina* or treatment plant. The cars are dumped over bins which have little storage capacity as a plant has a limited number of boiling tanks, and when these are filled no more material is brought in from the 'fields'. From the bins chutes lead to crushers, the caliche (or caliche and costra) being reduced to 2-in. size; rolls are also used, placed below the crushers, but no arrangements are made for screening, so that there is an unnecessary making of 'fines'. The ideal product for leaching is the coarse size (about 2 in. diameter) with a minimum amount of 'fines', as the latter tend to cake in the boiling tanks and prevent thorough percolation of the solutions. The treatment of the fine material, separately, is receiving attention and experiments are under way. The crushed material is hauled up an incline, to the boiling tanks, in a three-ton, side-discharge, hopper-bottom, steel car and automatically released, then moving on a slight down grade parallel to the tanks (locally called *cachuchos*). Each series of tanks are trestled, at right angles to their lengths, by two lines of track (30-in. gage); the loaded car moves on a turntable and is 'spotted' where needed. The tanks, made of $\frac{1}{4}$ -in. or $\frac{3}{8}$ -in. iron plate, are 9 ft. wide, 24 ft. long, and $7\frac{1}{2}$ to 8 ft. deep, holding approximately 900 quintals (under 45 tons) of caliche. Each tank has a false bottom, of perforated plate with 7 16-in. holes staggered 2 in. apart, that stands 8 in. above the real bottom. Two bottom discharge gates, (each one foot square) serve as discharge for the leached caliche (locally called *ripio*) to 3-ton cars that are run in below the tanks and hauled up an incline to the waste dumps. In the early days of the industry this

contained up to 20% NaNO_3 ; at present the ripio averages from 7 to 10% NaNO_3 . A series of four turns of 3-in. steam coil passes around the sides, inside of the tank. Through this live steam, at 25-lb. pressure, circulates. The material to be leached is heated up to 90° Twaddell. Mother liquor originally from the crystallizing tanks, containing about 30% NaNO_3 and 13% NaCl , is run in over the caliche and left 6 hours in contact from the time steam is turned on. Each tank is connected with its neighbor by means of a siphon, which draws off the solution below the false

bottom (called the crinolin plate) and discharges it into its neighbor at a point about two-thirds up the height of the tank. The siphon pipes are so arranged that the liquor must pass diagonally from one end of the tank to the other, and from the top down. The tanks are connected in series of four. Every pipe connection, between the tanks, has a discharge valve for drawing off the solution below the false bottom, and a bottom discharge plug for cleaning out below same. Three other pipe connections exist for admitting cold mother liquor, and wash, and fresh waters.

Pressure and Vacuum at Altitude

By A. W. ALLEN

The elevation of the plant above sea-level must be taken into account when estimating the possible duty of a number of machines used in cyaniding work. The following table of approximate pressures, for different elevations, may prove of use:

| Altitude. | Atmospheric pressure per square inch, pounds. | Equivalent in water column, feet. | Equivalent in mercury column, inches. |
|------------------|---|-----------------------------------|---------------------------------------|
| Sea-level | 14.7 | 34.0 | 30.0 |
| 1,000 feet | 14.2 | 32.9 | 28.9 |
| 2,000 " | 13.6 | 31.7 | 27.8 |
| 3,000 " | 13.1 | 30.6 | 26.7 |
| 4,000 " | 12.7 | 29.5 | 25.7 |
| 5,000 " | 12.2 | 28.3 | 24.8 |
| 6,000 " | 11.7 | 27.2 | 23.8 |
| 7,000 " | 11.3 | 26.1 | 22.9 |
| 8,000 " | 10.9 | 25.0 | 22.0 |
| 9,000 " | 10.5 | 23.8 | 21.2 |
| 10,000 " | 10.1 | 22.7 | 20.3 |

The theoretical fixed pressure output from a compressor will decrease to an amount varying with the altitude and also the pressure required. To produce equal volumes of compressed air, at the same gauge pressure, it is necessary to handle increasing volumes of free air according to elevation of the plant above sea-level and gauge pressure required. This increase may be taken as a rough guide in estimating the increased cost of compression; the same ratio referring to the increased expansibility of compressed air at elevation.

The maximum suction lift will decrease, at elevation, in direct proportion to the figures given in the table of water column equivalents. These figures indicate theoretical lifts which are not realizable in practice to within 80 per cent. In pumping solids in water, or other diluent, an allowance must be made in proportion to the specific gravity of the mixture. The actual possible lift is also influenced by the class of pump erected, the care with which the joints have been made in the suction pipe, and a number of other considerations.

For each 1000 ft. of elevation a deduction should be made roughly equivalent to one-thirtieth of the

vacuum obtainable by the same type of pump at sea-level. In vacuum filtration at high altitudes the initial vacuum may be sufficient, but the capacity of the filter will rapidly decrease as the pores of the canvas become clogged; and the necessity for frequent treatment or replacement of the material will become apparent. Expensive and difficult transport may involve a prohibitive cost for the acid cleaning of the cloth. In the latter event, the adoption of a system of pressure filtration should be considered.

The air lift, when properly constructed and operated, may be considered as an ideal expansion engine. The air, at the conclusion of the work, should escape at little above the pressure of the surrounding atmosphere. It follows, therefore, that the extra cost of air compression at an altitude is, in this system of pumping, balanced by the increased expansibility of the air when compressed. Air-lift operations at high altitudes are therefore as economical as at sea-level.

In the Frier pump the air is compressed during the revolution of the spiral; and, since the height of lift is practically dependent on air pressure, it follows that this type of pump is affected by altitude in the same way as the compressor. If sea-level results are expected at an altitude, a spiral of large diameter must be used. The makers suggest a deduction of four inches from the sea-level lift for each 100 ft. of elevation when spirals of the same size are under consideration.

The Hudson River region produced 1,025,308,000 bricks in 1913, valued at \$5,636,061, according to Jefferson Middleton, of the U. S. Geological Survey. Large as these figures are, they show a decrease of 207,879,000 bricks and \$1,497,116 in value compared with 1912. New York City is the leading market for common brick in the United States, hundreds of millions of bricks being used there annually.

Undercutting machines have been an important factor in increasing the per capita production of miners in District VII of Illinois, to 5.1 tons of coal per day, compared with 4.5 tons for the whole state.

Making Ductile Tungsten

The following abstract of a description by R. W. Moore of the methods used in preparing ductile tungsten which appeared in *Met. & Chem. Eng.* is given by *Chemical Abstracts*. Scheelite is decomposed by HCl, yielding impure WO_3 . This is further purified by solution in NH_4OH , and re-precipitated by HCl. Wolframite is fused with Na_2CO_3 , the mass is dissolved in water, and WO_3 precipitated by HCl. The crude WO_3 from either of the above processes is roughly reduced by heating with C and yields impure tungsten; worth about \$1 per pound, which is used in the steel industry. For making ductile tungsten, the crude WO_3 , which may contain salts of Fe, Mn, Ca, Mo, P, As, Na, and Si, must be further purified by one of the following methods: (1) The crude WO_3 is dissolved in NH_4OH . The solution is filtered and evaporated, yielding ammonium paratungstate crystals. The crystals are washed, dried, and decomposed by heat, leaving WO_3 . This oxide is very pure. (2) The crude WO_3 is dissolved in NH_4OH . The solution is filtered and the WO_3 again precipitated by HCl. This method does not remove P and As. (3) The crystals obtained in the first method are decomposed by aqua regia. The purified WO_3 obtained by any one of the above methods is reduced by heating with either carbon or hydrogen. The reduction by hydrogen is carried out by placing the WO_3 in an electric tube furnace and heating it slowly to about 1000° while a slow stream of pure dry hydrogen is passed through the furnace. The reduced tungsten is in the form of a fine gray or black non-crystalline powder. This powder is placed in a mold and pressed into the form of a square bar. The bar is sintered at a temperature of 1300° in an atmosphere of hydrogen in an electric tube furnace, by which treatment it becomes strong enough to stand ordinary handling. The bar is next placed in an atmosphere of hydrogen and treated nearly to its melting point ($3200^\circ C.$) by passing a large current through it. By this treatment the bar becomes very hard, but not ductile. Then the bar is heated to about $1500^\circ C.$ and swaged while hot into the form of a round bar. The hot swaging is continued until the bar is reduced to a diameter of 30 mm. During the operation of swaging the metal is made ductile. It is now drawn through diamond dies while hot ($600^\circ C.$) until it is small enough for lamp filaments. When tungsten is made into other forms than wire, it is rolled or forged hot, since it is too hard to machine when cold. Tungsten has a high tensile strength, and is not attacked by damp air or any single acid. It is dissolved by a mixture of hydrofluoric and nitric acids.

Railroads in the United States, during the year ended June 30, 1913, carried a total of 2,009,462,000 tons of freight, 300,558,334,000-ton miles. Passengers carried numbered 1,018,283,000, the first year that the billion mark was exceeded.

Car Dump

The accompanying sketch shows a simple car dump used in iron ore mines, in the sub-levels where the ore is dumped into ore-chutes. The rails extend to only 18 in. from the collar of the chute, and a drop of $4\frac{1}{2}$ in. is allowed for the front wheels of the car. The round timber collar at the chute is shaped so that the

front end of the car frame strikes it when the wheels drop. The car should dump at an angle of 45 degrees. It is evident that the car wheels are close together which, of course, makes for easier tramming on rough tracks. In some mines, where the distance is short, steel wheelbarrows are used in the subs in place of cars. The poles across the raise have saved the lives of many men who fell into the chute.

Expenditure at Panama

Operations at Panama Canal have attracted considerable attention, and now that the waterway is nearly ready for traffic, the following cost of the work should be of interest. To January 31, 1914, according to *The Canal Record*, the total was \$317,397,016, made up by department of civil administration, \$6,833,954; law, \$56,392; sanitation, \$16,961,623; construction and engineering, \$199,937,199; general items, \$89,458,448; and fortifications, \$4,149,400. Details of construction cost to the end of 1913 are as follows:

| | | | |
|----------------------------------|--------------|--------------------------------------|--------------|
| Gatun spillway... | \$ 3,431,765 | Miraflores locks... | \$17,566,326 |
| Gatun dam..... | 8,690,831 | La Boca locks and | |
| Gatun locks..... | 29,189,290 | dams | 632,999 |
| Gatun hydro-electric plant | 568,800 | Pedro Miguel to the sea, total.... | \$48,851,314 |
| Gatun-Mindi levee. | 106,492 | Cristobal, terminal facilities | 221,763 |
| Gatun to the sea, total | \$53,756,184 | Balboa, terminal facilities | 4,555,951 |
| Gatun to Pedro Miguel | 86,983,245 | Townsites | 354,251 |
| Pedro Miguel dams | 365,314 | Permanent buildings | 122,970 |
| Pedro Miguel locks | 12,126,012 | Power transmission system.... | 449,342 |
| Miraflores east dam | 983,252 | Oil pipe, lights and buoys | 523,162 |
| Miraflores west dam | 964,623 | | |

Total construction cost

These costs include administrative and general expenses, but do not include general items, or expenditure for sanitation, hospitals or civil administration.

Power used in the Cobalt district, Ontario, amounts to 13,000 horse-power.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

American Investments in Mexico

The Editor:

Sir—I have just read with great interest your editorial in the issue of May 16 on 'American Investments in Mexico,' and I wish to express my appreciation of the same.

It seems to me that you have stated fully and concisely the facts of the case, and your opinion corroborates what I have learned from reliable men who are familiar with present and recent conditions in widely separated parts of Mexico. It is indeed a relief to read such an article after perusing so much inaccurate and foolish writing that one meets in the daily press.

My own experience in western Mexico the past year and a half bears out your conclusions, and I have no misgivings for the future in Mexico. Too many Americans resident in Mexico who ought to know better, and most of the people on this side of the line, have no knowledge of or sympathy with the ordinary Mexican character, which is very necessary to enable one to form a valid opinion of Mexican affairs.

E. P. CRAWFORD.

Silver City, New Mexico, May 21.

Survey Publications

The Editor:

Sir—In a letter from F. L. Ransome in your issue of May 2, 1914, I note that the United States Geological Survey is now, and expects to continue, sending geologists to the various new districts for the purpose of making brief reports, which are promptly issued in bulletin form, and which are later to be incorporated in general summary volumes on the geology and ore deposits of each state. The volume on New Mexico, which has already been published, is most valuable to the engineer and prospector who wishes to obtain information concerning the ore deposits of that state, and I am glad to note that other volumes, for Arizona, Idaho, and Utah, are in preparation. These volumes, and especially the bulletins, should be of considerable value to the prospector, and every effort should be made to call the attention of the prospector to the fact that these bulletins are being published and that they are free. I venture to say that a majority of the prospectors are not aware that such data are available or where they can be obtained, wherefore it would appear most advisable to give as much publicity to the work of the Geological Survey as is possible.

For several years I have been keeping a loose-leaf file of data on practically all of the mines of the United

States, and among these data I find a considerable percentage of references made to the Geological Survey publications, thus indicating to me that the Geological Survey has been fairly active in the examination of the various mining districts. That improvements might be made is always possible, because new conditions arise whereby new information, and also new methods of obtaining and disseminating information, are required.

In some quarters a misconception prevails as to the information that a geologist can supply. I have heard prospectors and even engineers criticize the Survey publications in that they do not tell them just where to find a body of ore. Based on the observations made in the same district and also in other districts, the geologist may be able to indicate in a general way the more favorable points to prospect, but he does not pretend to state definitely just where an orebody is to be found. Only the charlatan with the dipping needle will pretend to do that.

Inducing Capital into Mining Enterprises

The Editor:

Sir—I have noticed the very good comments appearing in your paper on 'What Is the Matter with Prospecting?' and while this subject is before the profession and public it might be a good idea to take up the kindred subject of the obtaining of money to develop and operate properties on which enough work has been done to warrant the expenditure of further capital.

Much has been written on this subject, and in giving my views and experience, I do it not for the benefit or criticism of those well known engineers and successful promoters whose name on a favorable report will guarantee ample capital for the investment, but rather for those not so well known, who often have meritorious propositions submitted to them and who fail when it comes to getting enough capital to finance their enterprise.

For the sake of elimination, I will divide mining into two heads: coal and iron mining and kindred minerals, and the mining of precious and semi-precious metals.

Coal and iron mining is usually conducted by large interests who use the products, directly, in their manufacturing or railroad plants. Good properties, of this class, are in demand by these interests, who have their own engineers constantly in the field, looking for such properties. There is no complaint concerning the hesitancy of capital to enter this field of mining, as the demand is strong and the supply limited.

It is in the field of precious and semi-precious metal mining where capital seems backward, and where the big howl goes up from the promoters and miners. In this field the demand is light and the supply fairly large. There are, at present, about a dozen large

companies, throughout the world, who make mining a business. These companies are always looking for developed properties, where they can obtain a large return for their money, and as long as the demand among the general public for mining properties is light, these companies will continue to dominate the markets and to pick up properties at their own figures or leave them in idleness.

The sale of mining properties, like all other commodities, follows the law of supply and demand, and whenever the demand is light there is no use of the promoter and prospector turning to the larger companies and then becoming discouraged if these companies offer prices which are not commensurate with the value of the property. The promoter must turn to other fields. He must turn to the public and show them that they will get good returns from their money by a company capitalized both with that idea in view and the idea that the owner will get a price commensurate with the value of his mine.

One instance is recalled wherein a merchant bought a small prospect and developed it for a few years. He then had the property sampled by reputable engineers and his ore tested by reputable metallurgists. He found that after paying for all mining and milling equipment and all operating costs and plant depreciation there would be a net profit from the ore in sight of about \$275,000. He offered the mine for sale to a large mining company, which offered him \$75,000 for his property. Of course, he turned down this offer and was highly indignant that such a company should offer him such a meagre figure. He then consulted a small banker. This banker called in another engineer, who checked the owner's figures on the property. This engineer was well posted in financial matters, knew the trend of the public investments, and suggested that the banker sponsor a company of \$400,000 capital. This the banker was willing to do, for a small consideration, so the company was floated by the help of this banker's name and the mining and milling reports of the reputable engineers. The stock was oversubscribed (the stock was sold at par), the owner received \$200,000 for his property, the mine was developed under good management, a mill erected, and the investors received, and are still receiving, good returns on their investment.

It is hard, at any time, legitimately to float a prospect, as it is too much of a gamble in most cases. Therefore, my discussion will not take in that class of property, but will deal with properties on which there has been enough of development work done to warrant a sale being made to the public. The question is how to induce the public to take an interest in the mining of precious and semi-precious metals. Prior to 1907 almost everything was done to discourage the public from entering this field. A little history might serve to illustrate this point.

Precious-metal mining had its first great impetus, in this country, from the finding of placer gold deposits in 1849 in California. In those days a man

could take a pick and shovel and sluice, and by working hard could, if he found good ground, make a fortune from his labors without the expenditure of much capital for development or equipment. His gold was readily salable, so he had no reduction processes to contend with. That idea, in regard to all mining, has stuck in the public mind ever since, and when the lode mines were discovered on the Comstock the public thought that the returns would be the same as from placer mining; that little good management was needed, or there was not required much money for development or equipment. As a result, thousands of companies were floated, based on undeveloped or partly developed prospects, most of these companies not having sufficient capital to rightly work their properties. When it was realized that more money was needed, the public could not see it that way, and regarded the properties as worthless, losing money and leaving the prospects undeveloped, a great many of these prospects proving very rich when worked later by mining companies whose managers realized that it took capital and good management to make a mine out of a prospect. The exceptions to this rule, and they are very few, are those properties having high-grade ore from the grass roots. It was the striking of high-grade deposits of the exceptional kind which started the Goldfield and Cobalt booms. Because a few of the companies had this high-grade ore from which they made large fortunes without the expenditure of much capital, crooked and reckless promoters took advantage of this fact in getting money from the public, making the plea that companies with small amounts of actual cash capital could make great fortunes. Believing this and remembering the days of '49, the public was 'stung' to the amount of over \$400,000,000 in 1905 and 1906 by taking stock in companies owning prospects that were either worthless or on which not enough capital or good management had been spent to make a mine.

Since 1907 the public has been pretty well educated as to what real mining is, and what is required before dividends are forthcoming. They have been educated by our mining and daily papers, and by our great engineering societies and our government and state sustained mining bureaus. While these bodies have been working to educate the public along the lines of entering legitimate mining enterprises, the general business of the country is trending to open the eyes of investors to the good returns to be obtained from mining investments.

Formerly the investor put his funds into the securities of railroad and industrial concerns, as these offered a good return upon his capital. However, since the large demands of labor and the advent of regulations imposed by our law-making bodies, this class of securities does not offer such good return as formerly to illustrate which, one might use the recent New York, New Haven & Hartford episode. Therefore, there was or is a dearth of investment in such securities, and the investor turned to the securities of

power and public utilities companies. Now many of the state legislatures are making laws regulating prices at which power, light, heat, and public utilities, in general, are to be sold, so that profits will be small and the investor will withdraw his funds and with additional savings will seek investment with good returns.

There remains but one line of investment open, to obtain the desired return, and that is the development of the country's natural resources, the development of which will not be retarded by adverse legislation to such a degree as materially to affect the return upon the investment. In this line comes the mining of precious and semi-precious metals, and I believe that from this time on the investor will look more into investing in mining securities.

Another incident, that is not of importance at the present time, is the collection of the personal state tax. The personal property tax in some states is so excessive as to be confiscatory, so that the people pay this tax on only a minor portion of their property. The tax collectors realize this fact and do not ask for an inventory; they take the taxpayer's word. Under the new federal income tax law, one must file an accurate report of all income over \$3000, or \$4000 if he be married and living with his wife, from personal or other property. When the state tax collectors see these inventories filed for greater sums than declared to the state, they may try to collect the full tax on all personal property. To cite an example: One of our states, I understand, claims a tax of $2\frac{1}{2}\%$ on the market value of all personal property. In this state there resides a capitalist who owns \$15,000,000 in bonds of an industrial corporation on which he receives 5%. The bonds are selling at par. Under the state tax he would have to give half of his income to cover this tax, and his investment would then net him $2\frac{1}{2}\%$. His state tax, heretofore, has been based on \$10,000 of personal property. It will be interesting to note if the personal tax collector will base his future taxation on the old \$10,000 or upon the \$15,000,000 inventoried from income under the federal income tax. In most cases semi-precious and precious metal mining stocks do not reach par, on the market, until the dividend reaches about 10%; so if this capitalist had his principal sum invested in mining securities he would receive a net income of $7\frac{1}{2}\%$ after the personal tax, as compared with $2\frac{1}{2}\%$ as at present. A few of the mining stocks do not pay more than 6% on the market value, but these are the larger mining companies and their stocks, based on dividends, do not follow the market trend of the stocks of the smaller companies. Market or personal tax conditions may adjust themselves if the personal tax should be collected in full; but in any case, I believe that mining stocks will have the better end of the argument.

The larger companies, when they want public subscriptions, usually give reports from reliable mining engineers and metallurgists to their prospective investors, and their stock allotments are usually over-

subscribed, simply because they understand their business. Therefore, how can the promoter, working on a smaller scale, expect to interest the public without giving them the detail that the larger companies know is necessary to successful flotations?

A mine with good ore in it is not always a safe investment, as there must be some method to treat the ore and return a profit, especially where the ore is low in grade, when local treatment must be resorted to. The investor now realizes the importance of the reduction process. Being in the metallurgical end, I know that there are more reduction process inquiries out and more ore being tested at this time than there has been for a great many years.

Now that things are trending toward public investment in mining, and the public having been taught the legitimate mining game, it might be well for the promoter to have reports on his property by reliable engineers and metallurgists, and if he cannot sell to the large companies, try the public in smaller units. To the owner there is sometimes more to be gained by taking some stock or convertible bonds for his property than by taking cash payments. This latter method often facilitates the initial financing of the company. The time is ripe, and capital, like all other liquid bodies, will flow along the line of least resistance. Give the investing public a good legitimate property and a square deal, and they will invest; otherwise, you will find them using the great railroad slogan of the day, 'Safety First.'

CARL J. TRAUERMAN.

Butte, Montana, May 10.

Revision of the Mining Law

The Editor:

Sir—I notice there is considerable interest being taken regarding the Mining Code Commission for the revision of our present mining laws among those who are interested and engaged in mining. In your editorial of April 4 you stated rightly that the Commission ought to be composed of more mining men. Most of us believe that new laws should be made, and discussion, by those who are interested in mining, in the mining press of the country, would have considerable weight in the making of the new laws. Strict fundamental laws in regard to location and title is what is necessary, and from my observations I believe the following, if put into law, would be of some help:

1. Location of a mining claim to be made by those only who are citizens of the United States and those who have declared their intention to be such.

2. Size of a mining claim to be 1320 ft. in length by 660 ft. in width.

3. Discovery monument 4 ft. in height or stake 4 ft. in height, with the notice of the location to be at the northeast corner of claim.

4. Boundaries, side and end lines to be marked by stakes, rock, or dirt monuments at least 2 ft. in height and not to be over 100 ft. apart on the side and end lines, the corners to be marked by stakes at least 4 ft.

in height and 4 in. square, marked with name of claim and what corner.

5. Discovery work to consist of a shaft not less than 6 ft. in depth; adit or open cut, not less than 6 ft. in depth at face.

6. To describe accurately the location of claim from some fixed point, like section corner or known prominent place or object.

7. No extralateral rights; vertical side and end lines.

8. Claim to be recorded in 60 days from date of location, location day inclusive.

9. No overlapping of claims.

10. Heavy fine with imprisonment for back dating.

11. The first day of July to be the first day of the year relating to mining locations.

12. The locator or owner of a mining claim to pay the state or Government an annual tax of \$10 per year to hold said claim, said \$10 tax to be paid, if so wanted by owner of claim, in \$5 payments to cover a period of six months, ninety days from date of location.

13. The locator or owner of a mining claim can, if so desired, secure patent for same upon complying with the following requirements: to have paid the tax for three consecutive years; found mineral in place; made improvements to consist of at least 1000 cu. ft. of rock or dirt removed from excavations made by shaft, adit, or tunnel from surface or underground workings as development work; price of land \$10 per acre, to be paid the Government.

14. To reserve all mineral rights on subsequent agricultural filings, with certain surface reservations, these mineral reservations to be had by complying with the mining laws in force at the time said agricultural filings are made.

15. No location of mineral ground can be made by proxy or power of attorney and only in name of the actual locator.

When one goes deeply into the subject, he will find in the present mining laws and rulings nothing to commend them. The public wants laws enacted and put in force that will benefit the mining industry and be of some help to those that are engaged in it. Under our present laws, an alien can locate, hold, work, and sell an number of mining claims, but cannot get a patent. Changing the size of a mining claim from the present size to one of 1320 ft. in length by 660 ft. in width would be much better and more beneficial both for title, patent, and in other ways. The change in size would allow the location of a mining claim to be made in certain legalized subdivisions of surveyed sections; fully 50 per cent of subsequent locations and patents would be designated by the subdivisions of sections, doing away with the heavy survey cost and tying up the claim proper for all time.

The first day of July of each year would be the most convenient day for the start of the mining year in relation to mining locations. There are always a great number of locations made on the first day of the year in all of the mining districts, and in most of the

places the ground is covered with deep snow.

But the greatest change for the good of those who do own mining claims would be the annual tax of \$10 per claim; something on this order is the only thing which would give one an absolute good title for an unpatented mining claim. The present system of requiring \$100 assessment work is not only evaded but is wasteful; in a majority of cases it is like making the owner of a mining claim throw \$100 into the fire and burn it up for the privilege of holding the claim one year, for all the good it does. Some claim it makes more development, but from my observation I believe it retards good development. In most places the work is done in some soft place where a certain amount of work can be done the easiest. It does not give the owner of the ground a good title; the claim is always open to 'jumpers'; the owner can swear he did the work, the others can swear he did not; there are a thousand bad features in this part alone. The only thing that should give title would be the tax receipt. People have owned and worked certain claims for a great number of years, and then suddenly, through some small technical ruling about the work, have lost the claim. There would not be any more claims held than now—maybe not as many. What work would be done would be true development under an annual tax. Poor, uncivilized, and revolutionized Mexico has us beat many ways on this. I notice some writers in discussion favor the Canadian laws relating to mining; but deliver us from those laws—one-man commission and the like. Many will remember how they construed those laws some years ago, repudiating the valid claims of the Americans in the Atlin district. Also, when the boom was on around Dawson, when claims were located by numbers, as 'one above' or 'two below discovery,' men stood in line for hours in that beautiful Italian climate to put their claims on record, only to be told 'Claim already located and recorded.' In South Africa and some of the colonies it is very nearly prohibitive for an individual with small means to hold and own mining ground.

In our agricultural laws a homesteader knows just where he stands, his requirements, and definite legal subdivisions of his land. This is what is needed for mineral lands—laws that are not to be so construed that white can be made black. Much of the future prospecting and mining will be done in ground where mineral deposits do not show on the surface. Results will be had from diamond-drilling, deep workings, and the like. The revision to be enacted should be made to construe laws not only for the present but for the future. It is only a short time before new laws will be enacted, and I believe like the fellow that said when he spit his fuse: 'Now is the time to holler—not when the shot goes off.'

FRANK P. DAVIS.

Fluorine, New Mexico, April 15.

We believe with our friend that now is the time to have your say about changing or not changing the mining laws. Who else speaks? EDITOR.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Potash shipments from Germany in 1913 were 1,166,600 metric tons, of which 531,300 tons was exported for foreign consumption.

The co-efficient of expansion of platinum is about the same as that of glass. This fact accounts for the general use of the metal as a connection between the outside and inside of an incandescent lamp.

Poisoning water hyacinths in Gatun lake, Panama, is now being done. A solution of 25 lb. of arsenic, 25 lb. of soda, 25 gal. of water boiled for one hour, is mixed with 425 gal. of water, and then sprayed on the plants. In about ten days, a plant so treated is apparently dead.

Sharpening drill steel by machines is economical and generally satisfactory, though some miners do not like bits produced by a machine. On the Rand, it is said that 80% of the bits employed in the Main Reef mines is sharpened by hand, although there is an economy of about \$9.36 per 1000 bits in sharpening by machines.

Cyanamid is a dry, grayish black, pulverized material, which is made by combining pure atmospheric nitrogen with calcium carbide at a temperature of 1100 to 1200°C. Its principal use is as a source of nitrogen in mixed fertilizers. The world's output for 1914 is estimated at 275,000 tons, worth at wholesale prices about \$14,000,000.

Mine bell signals should be posted in the station of each level in some conspicuous place. Generally the signals are printed on white duck cloth, or on oilcloth. In Kalgoorlie mines, the salt water eats out the ink, and recently the cloth signs at the Perseverance were replaced by enameled steel plates, on which the lettering stands out in blue on a white background. These plates are neat, and are practically indestructible with ordinary wear and tear.

A black bug or beetle, locally called the slag-bug, is found around the Montana smelters in the summer, and its favorite place of attack is the back of the neck of the smelterman, where its nip or pinch causes some discomfort and strong language. A similar insect is found at Kalgoorlie, Western Australia, where it delights in diving into heaps of hot ash from boilers and roasting furnaces. It also nips hard and goes under the name of slag beetle, asbestos beetle, or salamander.

Steamers engaged in the ore-carrying trade of the Great Lakes total about 400, which have a capacity of

55,000,000 tons of ore per season of seven to eight months. They also carry large quantities of coal, grain, copper, and salt. The Pittsburgh Steamship Co. owns 105 boats. During 1912, ore was transported an average distance of 1000 miles, for as low as 50c. per ton, boat owners paying the unloading charge of 10c. per ton. Some of the newer boats are as follows: *Col. J. N. Schoonmaker*, 617 ft. long and 14,000 gross tons; *W. P. Snyder, Jr.*, 617 ft. and 14,000 tons; *Thomas F. Cole*, 605 ft. and 12,000 tons; *L. S. De Graff*, 605 ft. and 12,900 tons; and *W. B. Kerr*, 605 ft. and 12,300 tons. A boat of 10,000 tons is usually loaded in six hours; but 9456 tons was run into the *Corey* in 1911 in 25 minutes. The

A LAKE ORE CARRIER.

W. P. Palmer was unloaded of 11,000 tons in 2 hours, 58 minutes. The accompanying picture of an ore steamer was recently taken near Marquette, Michigan.

The presence or absence of smoke at the top of any stack is not of itself a proof that the plant is being inefficiently or efficiently run, or even improperly or properly operated, although it is popularly so considered. Many boilers which are being operated with little or no smoke would show low over-all efficiency if tested; whereas others from which much smoke is being emitted would show that the fuel is being economically utilized according to Samuel B. Flagg of the U. S. Bureau of Mines, Pittsburgh. Such cases may be said, however, to be the exception rather than the rule, as the smoky stack is usually an indication of inefficient or improper operating conditions. This statement is borne out by results of many tests conducted at the government fuel-testing plant at St. Louis in 1904-1906. If the requirements for complete combustion of coal are complied with, it is obvious that smoke will be prevented, for the reason that smoke is an indication of incomplete combustion. The requirements are: (1) that the necessary air for combustion be supplied; (2) that the gasified fuel and air be intimately mixed; and (3) that the mixture be at a temperature at or above that at which the combustible gas will ignite or burn.

Special Correspondence

LONDON

PROPERTY OF THE BURMA MINES, LIMITED.—GEOLOGY, EXTENT OF VEINS, METAL CONTENT, AND ORE RESERVES.—WORK TO BE DONE.—ORE SHIPMENTS.

The event of last week in May was the public rehabilitation of the Burma Mines, Limited, by H. C. Hoover and his friends. This Company was formed by Bewick, Moreing & Co. in 1906, as a reconstruction of a company registered in 1904 to acquire a lead-silver mine, and heaps of ancient lead slags at Bawdwin, near Lashio, in the Northern Shan States of Burma, not far from the Chinese border. The treatment of the lead slags yielded some profit, but the funds so obtained, together with considerable additional capital, were spent in reopening and exploring the mine. Development was hindered by the large amount of water, and it was only by driving a drainage adit that further work was made possible. The orebodies were discovered to be of great extent, and to consist of mixed sulphides similar in character to those of Broken Hill, Australia. The Burma Corporation was formed six months ago by Mr. Hoover to help finance the Company. This Corporation has now issued 100,000 shares, bringing the total issued capital to £757,410, and has given a call on 200,000 further shares. A pamphlet has been issued containing a report on the properties signed by the technical committee of the Corporation, which is composed of R. Gilman Brown, Theodore J. Hoover (alternate A. F. Kuehn), and E. Heberlein. From this report I extract the following information:

The ore-channel of the Bawdwin mine is from 350 to 500 ft. wide, and has been traced for 8000 ft. The active work by the ancients, and by the present Company, has been confined to the northern 4000 ft. The ore occurs in nearly vertical shoots with a hanging wall of felspathic grit, and a foot-wall usually of rhyolite, and sometimes of felspathic grit. The ore-channel is covered by more recent sedimentaries, which have been eroded at the northern end so as to expose the ore. The rocks in which the orebodies are found have been called the Bawdwin series, and the overlying sedimentaries the Banyan series. The ancient workers had mined the outcrop of oxidized lead ore apparently with the object of extracting the silver. The work started by the present owners has been devoted to the development of the sulphide zone, and may be roughly divided into three parts, namely, the vertical shaft, Chinaman adit, and Tiger adit sections. The vertical shaft has been sunk to 434 ft., at a point 1400 ft. from the north end of the ore-channel. Cross-cuts have been driven at the 102 and 171-ft. levels, intersecting old workings. The 300-ft. level is virgin ground. A cross-cut is now being driven at the 430-ft. level. In this portion two lodes have been proved, called the Burman and the Shan. In the 300-ft. level, the Burman lode for a distance of 190 ft. has an average width of 31 ft., assaying 32% lead, 16% zinc, and 37 oz. silver per ton, with a trace of copper. The vertical shaft cut the lode at 410 ft. The Shan lode is parallel to the Burman, about 150 ft. to the east. At the 300-ft. level a cross-cut proved the lode to contain copper as well as lead and zinc. The assays showed 99 ft. on the northern side, 4.1 ft. thick, to average 11.2% lead, 1.5% zinc, 1.9% copper, and 8.4 oz. silver, while 150 ft. of the southern part averaged 17 ft. thick, and assayed 15.4% copper and 7.8 oz. silver.

The Chinaman tunnel enters at a point 3650 ft. south and 100 ft. west of the vertical shaft, and intersects the ore-channel 1887 ft. south of the shaft, at a horizon corresponding approximately to the 171-ft. level in the shaft. The core of the Chinaman orebody consists of zinc-lead sulphide, about 500 ft. long and 44 ft. wide, assaying 29% zinc, 26% lead, and 22.6 oz.

silver per ton. This core is enveloped by ore higher in lead, to a thickness of 29 ft., and assaying 24.3% lead, 14.2% zinc, and 17.5 oz. silver. Then comes a zone of ore of lower grade, 70 ft. wide. The total length of the orebody on the 171-ft. level is 1187 ft. The lower-grade ore is not included in the estimate of reserve; it averages 7% lead, 5% zinc, and 5 oz. silver. Two other smaller orebodies have been cut in the cross-cuts.

The Tiger adit is being driven with the object of providing a working entry to the mine. Its portal lies on the Sterne river, at a point convenient for access to the Company's smelter at Nam Tu. It will be about 6000 ft. long, and will enter the ore-channel 500 ft. below the Chinaman adit and 660 ft. below the collar of the vertical shaft.

The estimates indicate 1,154,000 tons of ore as reasonably assured, with further excellent prospects at depth. The most profitable method of ore-treatment is being studied, but in the meantime the zinc-lead ore is salable to European smelters, who during the past few months have taken 7488 tons. The profit to the Company on the sale of the ore in this way would be \$9.60 to \$12 per ton, with the value of the total metal contents at \$62.40 per ton. The purposes to which the present issue of capital is being devoted are: the completion of the Tiger adit, the rebuilding of the branch railway, the erection of a concentration plant, the installation of a hydro-electric power-plant, and sufficient development to render possible the extraction of 300,000 tons of ore annually. It will take 2½ years to complete this program, and during the time it is intended to ship 2500 to 4000 tons of zinc-lead ore per month, and to continue smelting either on picked lead ore or on the copper-silver ore.

NEW YORK

DEVELOPMENT COMPANY OF AMERICA, SOME HISTORY.—BRADEN PLANT TO BE ENLARGED.—CHILE COPPER CO.'S PROPOSALS.—ANACONDA LEACHING PLANT.—DOME LAKE.—OIL INDUSTRY.

The suit, filed last week in the Supreme Court, of the Development Company of America v. the Southern Pacific Railroad Co. for violation of agreement, reveals rather interesting history of the Development company. It was organized in 1901 by George B. Beaton and consisted of a group of investors from the Middle West and New England, who were successful business men and bankers, but without experience in large-scale mining. The ambitions of the organizers were entirely out of proportion to their resources and experience, and it was not long before they controlled, through stock ownership, the Tombstone Consolidated Mines Co., Ltd., the Imperial Copper Co., Congress Consolidated Mines Co., Ltd., Poland Mining Co., Gila Copper Sulphide Co., Lookout Copper Co., and the Southern Arizona Smelting Co., besides holding a large interest in the London Arizona Copper Co. and its subsidiary, the London Range Copper Co. In 1910 the Company formed the Arizona, Mexico & Gulf of California Railroad Co., to continue the 22-mile long connecting line of railway built by the Imperial Copper Co. This line ran from Redrock, on the Southern Pacific, through Sasko to Silverbelle, Arizona, and it was the intention of the Development Company to continue it on to Puerta Lobos, on the Gulf of California, in order to give it direct communication with Tidewater. The Imperial Copper Co. made quite a little copper, producing 10,000,000 lb. in 1909. The Tombstone proved a bad investment, however, for although the Tombstone company installed one of the largest pumping plants in the country to unwater the mine, it was never able to get the water out, since apparently the underground levels had some mysterious connection with the Pacific ocean or some other equally inexhaustible supply. The complaint against the Southern Pacific company is based on the fact that, in 1910, when the Company was involved in the height of its high finance, F. W. Murphy, then president of

the Company, made an arrangement with Judge Lovett of the Southern Pacific for a loan of \$500,000 on the note of the Company, and, furthermore, that the Southern Pacific would buy \$3,500,000 of the capital stock of the Development Company, making payments of \$500,000 every quarter until paid for. Relying on this agreement, Mr. Murphy notified the creditors of the Development Company that it would be in funds on the date agreed for the making of the loan, and instructed them to draw on the Company on that date. The money was never forthcoming from the Southern Pacific, and as a result the Imperial Copper Co., as well as several other of the subsidiary companies, was thrown into bankruptcy, while the railroad construction had to be abandoned. Finally the Empire Trust Co. foreclosed on \$1,500,000 of the Development Company bonds, and sold all the stockholdings in the subsidiary companies which had been deposited as collateral. As a result, the Development Company of America practically went out of existence. It is not probable that anything will come out of the present suit, which is merely an attempt to save a little out of the grand wreck. The Development Company was capitalized at \$7,000,000 and had outstanding nearly \$4,000,000 in 6% debentures. The Tombstone was the heaviest load on the Company. The financing of the whole scheme was faulty from the beginning, and it was not remarkable that it came to grief.

property, Pope Yeatman has given out a statement to the effect that the reserve will in all probability amount to nearly 300,000,000 tons of 2.1% ore, and accordingly suggests that the 10,000-ton plant now under construction be increased to 30,000 tons per day. No statement has yet been made as to whether this plan will be carried out. In all probability the actual results of the 10,000-ton mill will be awaited before beginning construction of the larger one. A good many engineers think that the management is displaying almost foolhardy courage in building so large a plant without first testing the process on a working scale in a small plant. On the other hand, it must be said that the success of some of the operations depends on their being carried out on a large scale, and the results obtained in a small plant would not be a conclusive test of what could be done with a larger one. The Chile Copper Co. already has a bond issue of \$15,000,000 authorized, and if more funds are required for construction, presumably this issue and the amount of stock will be increased.

The Anaconda is decreasing its output, while the construction of its leaching plant for the sand tailing and the slime concentration plant is under way. Treatment of all low-grade ore at Great Falls is to be discontinued, and all the milling will be concentrated at Anaconda, thus making a considerable saving in freight rates on the low-grade ore. This

BRADEN CONCENTRATING PLANT, MOLINO, CHILE.

The Braden Copper Co. intends to increase its plant in Chile to a capacity of 10,000 tons per day, or three times the present capacity. This is a natural step, following the large increase in the ore reserve which has been announced during the past year. Providing the money for these increases is another matter, however, in the present state of business, and it is announced by the management that the financing necessary to carry out the program of expansion will not be attempted until next fall. A similar expansion seems to be planned for the Chile Copper Co., which, it will be remembered, has a developed ore reserve of approximately 200,000,000 tons of 2.1% ore. Since his recent return from the

ore will be concentrated according to the flow-sheet worked out at the Great Falls plant, and the sand tailing will be sent to the leaching plant now under construction. The slime tailing cannot be treated by leaching for obvious reasons, and will be sent to the round table plant. The thin pulp goes to 28-ft settling tanks, and the thickened pulp is drawn off and sent to the round tables which have 20 decks made of cement. The fine table concentrate, containing 8% copper, contains so much water and is so fine that it is dewatered on filters before being sent to the smelting plant.

The Dome Lake shareholders have authorized the sale of 100,000 shares of treasury stock at 50c. per share, and Temis-

kaming and Hudson Bay interests have agreed to take all of this issue that is not subscribed for by shareholders by June 9. The new issue will bring the capitalization to 850,000 shares. There is a 10-stamp mill, and it is reported that this will be put in operation soon. Development is in progress, and it is understood that the position of the Company is good.

The interest in mining in New York, to use a hibernianism, centres largely in oil production. The dealings in Standard Oil subsidiaries have become the leading feature of the Curb market in Broad street, which was for so long the chief arena for dealings with the smaller mining companies. The oil companies are nearly all making good profit, even in spite of the present depressed state of business. The continual development of the oil industry also helps to keep up interest in oil shares. The petroleum industry in Mexico, Venezuela, and Colombia are well known. It may not be so generally known that the drilling for oil is in progress in South Australia, and Australians hope to develop an important petroleum industry there. Some oil exploration in South America has been vigorous of recent years, and the latest report is that an important discovery of oil has been made in Bolivia, on the eastern slope of the Andes. The Standard Oil continues vigorous development of its new venture in China, and a large number of experienced oil geologists have been sent to carry on scientific study of the fields.

BOSTON

ALASKA GOLD MINES SHARES.—FALCON-WORCESTER OIL CO. AND EXCELSIOR CONSOLIDATED GOLD MINING CO.—STEPHEN R. DOW.—DAVIS-DALY AFFAIRS.—DRILLING IN MICHIGAN.

Officials of the Alaska Gold Mines Co. recently publicly deprecated the extravagant booming which has been given that stock in a market way. One of them expressed the opinion that the rise which the stock has already had to between \$28 and \$29 per share has been too rapid. A prominent Boston market operator, whose name it is unnecessary to mention, recently distributed 'tissues' on State street stating that he believed "Alaska Gold will go to 150, perhaps 200, 250, or 300," his exact words being used. He stated also that "he had investigated Alaska from top to bottom." The president and management of the Alaska Gold Mines are not expecting annual profits of more than \$2 at present, and later on of not over \$3.50 per share. With a mill of 20,000-ton daily capacity, the Company would earn, calculating the estimated rate of earnings, between \$6 and \$7 per share. It is doubtful that shares could ever sell at \$300 each, or even above the price of Amalgamated, which pays \$6 dividends, selling around \$72.

Samuel Klous, of Worcester, who has the management, in association with Worcester capitalists, of the Falcon-Worcester Oil Co., of Falcon, El Paso county, Colorado, and the Excelsior Consolidated Gold Mining Co. of Meadow Lake district, Nevada county, California, is now in the West looking after the initial drilling of the oilfield, and the opening of the mines. He has employed Henry J. Gray, of Denver, to take the local management of the mines, and J. W. Marshall, of Denver, has the local management of the oil company. State Oil Inspector Duce, of Denver, recently visited the Falcon field, which is at the junction of the Rock Island and Colorado & Southern lines, adjacent to the town of Falcon, and estimates that a flow of oil would come in at about 1700 ft. Numerous indications of oil and gas have been met with in drilling two wells down to between 1000 and 1100 ft., and the Worcester interests are confident that they will be able to develop a new oilfield in a district where transportation and market conditions are good. The gold mine management contemplates devoting its attention for the next year or two to blocking out ore underground.

Stephen P. Dow, who misappropriated about \$300,000 belonging to the Indiana, Franklin, North Lake, and Algonquin

companies, in the Lake country, of which he was president, lost his case on appeal before the Massachusetts Supreme Court and is obliged to serve in Charlestown state prison his sentence, pronounced over a year ago, of not less than eight nor more than twelve years. The jury found him not guilty of larceny as alleged in the indictment, but guilty on 24 counts of fraudulent misappropriation of the funds of these corporations while acting as their president. Dow was formerly a member of the Boston Stock Exchange, and rose from the position of office-boy to one of the most daring copper speculators Boston has ever known.

Davis-Daly shares on the Boston Curb recently sold down to 43c. each, a price of \$258,000 for the Company's entire outstanding capital. At this level the gambling element began to wonder if it was not a good speculation, and some concentrated buying set in. Since then the first installment of 25c. on the 50c. assessment has been paid. W. L. Creden, the manager, has made a careful study of the ground in which Davis-Daly is located for several years, particularly with reference to the course of the Rarus fault system, which has been so important in Butte ore development. The Davis-Daly is situated in the heart of Butte, from the business section point of view, 320 acres underlying the city, but it lies south and west of the proved mineralized system of Butte hill. Mr. Creden is confident that in sinking the Colorado shaft from 2000 to 2600 ft. he will open good ore. At \$10 par, Davis-Daly is an assessable stock, and \$9.50 per share will have been paid in when the present assessment has been met.

The most extensive campaign of drilling ever conducted in the Lake district, perhaps, has been done by the Mayflower and Old Colony companies, proving the Mayflower lode continuously over both properties, which are right in the heart of the copper country. About 75 drill-holes have been put down an average depth of 1500 feet.

WASHINGTON, D. C.

MINING LEGISLATION SLOW.—FUEL PURCHASE BILL.—NEW MINING DEVICES PERFECTED BY THE BUREAU OF MINES.—REPORT OF NATIONAL CONSERVATION COMMISSION.

Mining legislation in Congress remains at a standstill, waiting for an opportunity to be considered, which is not likely at this session, save in the bill to create a commission to codify the mining laws. This has passed the Senate and is now on the calendar of the House under another form, not differing much from the bill passed by the Senate. Of more immediate moment is the acceptance by the House of the clause in the Clayton anti-trust bill forbidding reduction works, and mine owners and operators, and the like, from not selling, when they are selling, their products, whatever they may be, to whomsoever shall reasonably and responsibly apply to buy. The clause was amended in the House last week to include water power, electric power, gas, and oil.

A new bill, introduced by Congressman Foster of Illinois, chairman of the House Committee on Mines and Mining, provides for the uniform selection and purchase of fuel to be used by the United States Government. All these purchases, whether coal, oil, or wood, are to be made or contracted for in accordance with recommendations and specifications prepared by the U. S. Bureau of Mines, whose duty it is to make investigations of fuel-burning equipments, the handling and storing of fuel, itself receiving full reports related to the subject from the departments of the Government. Payments for fuel are to be made in conformity with a statement, to be furnished by the Bureau, of the unit price to be paid. An appropriation of \$75,000 per year is provided to make the law effective.

Engineers connected with the U. S. Bureau of Mines have perfected six devices, five involving the saving of life and

one saving the waste of natural mining resources. A patent has been applied for every one of them, but is declared only to retain these devices for the people without payment of royalty and to prevent any commercial concern from gaining a monopoly in their manufacture. The most important of the inventions is the apparatus worn by miners while following disasters to effect rescues. It supplies oxygen to the rescuer, permitting him to enter poisonous gas and carry on his work for two hours: The study of perfecting apparatus to enable such work to be done had been entrusted to William E. Gibbs, consulting engineer of the Bureau, and the application for the patents is the result. Caustic soda is used in the apparatus in taking up the poisonous exhalations of the breath, being so adjusted as to permit a continuous flow of the expired air. The experiments made with the device are said to have been quite successful. A new type of valve accomplishes the reduction of the oxygen pressure from 2000 lb. per square inch to the proper amount needed. The wearer of the apparatus regulates it according to his needs. The weight of the breathing apparatus is reduced by 40%. The third invention is a collapsible mine cage, invented by George S. Rice; and J. W. Paul has invented an electrical signaling device for use in shafts following disasters. A person descending a shaft is enabled by it to signal to the hoisting engineer. If the man on the cage is overcome and the apparatus falls from his hands, a circuit is immediately closed and a gong in the engine-house gives a sudden warning. Applications have been made for patents for processes of extracting vanadium, uranium, and radium from ores such as carnotite. These processes are the results of studies in the Denver laboratory of the Bureau of Mines, and reduces, it is said, the cost of their recovery and prevents a monopoly which goes with the secret process now used for making them. It is estimated that these new processes will cut the cost of radium fully one-half, and perhaps more.

Gifford Pinchot, as president of the National Conservation Association, which has its headquarters in Washington, has made his report on conservation legislation in Congress for the year, and, of course, it embraces mining legislation, which conservation likes to patronize. The Association has opposed coal-leasing legislation, which could have been the entering wedge for the leasing of other mining properties, so far under the ownership of the Government. The Association has, in particular, opposed the bill of Senator Myers of Montana granting to the Republic Coal Co., a subsidiary of the Chicago, Milwaukee & St. Paul Railroad, more than 2000 acres of coal lands, officially estimated to contain over 10,000,000 tons of high-grade coal. The price fixed in the bill was \$82,000. Mr. Pinchot says that investigation has shown that the coal was worth about \$30,000,000. It is declared by him that the passage of the bill would have meant a reversal of the federal government's leasing policy. Mr. Pinchot still urges that the members of his Association use their influence to pass the Ferris Alaska coal-leasing bill, which involves the payment of a royalty to the Government. He also favors the radium bill, which is now dead, and also the water-power legislation, which has become quite a piece of legislation through the Ferris bill recently reported to Congress and of interest to mining men, for it has no small bearing on their industry.

TORONTO, ONTARIO

GEOLOGY OF THE CALGARY OILFIELD.—LIMITED QUANTITY OF THE 'WHITE OIL' PROBABLE.—AREA OF THE FIELD.—DEPTH OF WELLS.—SPECULATION IN OIL SHARES WATCHED.

Reginald W. Brock, Canadian Deputy Minister of Mines, who has just returned from an inspection of the Calgary oilfield, has issued a statement as to the real value of the find at the Dingman well, in reference to the question of the

existence of extensive oil deposits in the locality, which ought to render investors cautious. Mr. Brock, who is a recognized authority on the geological formations of oilfields, states that while the development strengthens the opinion always held by the Canadian Geological Survey that the Northwest affords a promising field for oil prospecting, it does not establish the existence of an important commercial field. The well, while much more profitable as a producer than a similar well yielding crude oil, is not as satisfactory an indication of the presence of oil in large quantities. Oil was met with at a depth of 2700 ft. and quickly rose to a height of 2000 to 2200 ft. in the well, being accompanied with gas, the escape of which occasionally causes a spurt of oil from the mouth of the well. The oil is a 'white oil,' like the small amount of oil found higher up in the well last fall, and is about 64.5° B., almost pure gasoline. In its crude state it is a satisfactory substitute in motors for refined gasoline. As the well has not been equipped with a pump, it was not known what the daily capacity would be, but the small amount bailed out had no effect on the level in the well. The previous find of white oil was regarded as representing the lighter and more volatile portion of a deposit which had filtered off from the main body, and the encountering of the same oil in greater volume leads to the supposition that the drill has made an approach to an oil reservoir. Mr. Brock is inclined to doubt whether there is any considerable quantity of the high-grade oil itself, as in other fields white oils have, as a rule, only occurred in limited quantities. The find, therefore, while encouraging, has not demonstrated the occurrence of oil in extensive commercial quantities.

The most important feature of Mr. Brock's observations, in view of the large area staked for prospecting and the number of purely speculative enterprises in the field, is his account of the geological formations of the neighborhood, showing the comparatively limited extent of the possible oil-bearing area. The Dingman well is situated at the base of the foothills, on the apex of a saddle-like fold in the rocks that makes a sort of lip to the great basin of rocks underlying the plains. This fold is a mile or so wide, dipping steeply on both its eastern and western limbs. Its direction is northwest and southeast, and it is cut off by a fault or break in the rock on its western limb. This is followed by several small folds, before the rocks become disturbed and broken toward the mountain front. The folds bring to the surface rocks lower in the scale than those found on the basins. While the Tertiary formation occurs on the plains, and the eastern and western limbs of the Dingman fold, the surface rock on this fold is the underlying Cretaceous. The possible oil-bearing rocks are low down in the latter formation, and the altitude of the rocks is favorable for the discovery of oil as it will rise to the highest point permitted by conditions underground. This consideration determined the location of the Dingman well on the apex of the fold. The geological structure limits the field for prospecting with any reasonable hope of success to a comparatively narrow belt, with a trend roughly parallel to the mountains. To the east of this, not only is the structure unfavorable, but the possible oil-bearing rocks were too deeply buried for the oil horizon to be reached by the drill, while westward the broken ground in the foothills limits any possible oil zone.

Investors are reminded that drilling in these formations is unusually expensive, and that to reduce the speculative element within commercial bounds it should only be undertaken under intelligent technical direction. Before investing, everyone should be assured that the company has sufficient capital to put down several wells, and that an engineer of repute has examined the ground and will locate the holes, and that he has pronounced it worth prospecting.

According to the latest reports, there were 57 oil companies operating in Calgary with a total capitalization of \$46,386.

000, with many others applying for incorporation. The provincial government of Alberta has taken action to prevent the publication of misleading advertisements, either in the newspapers or in office windows, etc. There is a penalty of \$250 for this offense, and the company convicted of it is liable to have its charter canceled. The Western Dominion Railroad has undertaken to construct a line from Calgary to the oilfield which will be carried on south to the American boundary, where it may be met by a branch of the Chicago, Milwaukee & St. Paul. The depths of the leading oil wells in the Calgary field are as follows: Dingman, 2718 ft.; McDougall, Segur, 2450 ft.; Black Diamond, 1580 ft.; United Oils, 1570 ft.; British Alberta, 1520 ft.; Southern Alberta, 800 ft.; Monarch, 640 ft.; Federal, 480 ft.; and Western Pacific, 300 feet.

MARQUETTE, MICHIGAN

ORE SHIPPING SEASON NOW ON.—PROSPECTING UNDER WAY.—
MINING NOT AT FULL CAPACITY.—CHARCOAL BLAST-FURNACES.—METALLURGY OF IRON ORES.

In the Lake Superior iron-ore districts, the shipping season has begun in earnest, although not at such a pace as in 'boom' times. As is usual in dull years, some old operators are doing little except maintaining their organization, while some of the smaller and more aggressive companies are hurrying their stockpiles away as fast as the steamers arrive.

As is also usual, dull times do not seem to affect extensive and expensive development work, and M. A. Hanna & Co., the Longyear interests, Pickands, Mather & Co., and several other companies are sinking shafts, stripping overburden, and equipping new mines. Diamond-drill exploration, on the contrary, is not so popular, due to several unfavorable features, one of which is the attitude of the state tax department in relentlessly raising assessments on new properties according to the 'Finlay system.' Another drawback is the fact that while Michigan's iron-ore territory has by no means been fully explored, nearly all the more convenient land has, and also some of the isolated tracts where swamps and inaccessibility make for expensive exploration. Jones & Laughlin, which concern neglected acquiring new properties until its old ones were nearly worked out, is doing a little quiet exploration, and the alert Cleveland-Cliffs Iron Co. is keeping its geological and diamond-drill departments at work. The Steel Corporation, with one or two exceptions, is keeping Michigan mines at low ebb, as it owns many of these properties or leases them on easy terms; but is maintaining a large production in Minnesota on account of the enforced conditions of the Hill iron ore leases, which stipulated that an increased tonnage should be mined from its lands every year and shipped over the Great Northern railway, all of which is a reminder of the astuteness of the 'empire builder,' James J. Hill. This is the last year of the Steel Corporation's holding of the Hill lands, which it is no doubt glad to release, as a royalty of \$1 per ton is out of proportion to the present low prices being paid for the ore.

The Cleveland-Cliffs Iron Co.'s charcoal blast-furnaces at Marquette, Gladstone, and Newberry, are either out of blast or will be soon, to permit of several months repairing, and to allow pig iron sales to catch up to stock on hand. It is no secret that the charcoal iron business has been for some time operating on a low margin, due to the dwindling of the differential in price paid for charcoal iron over ordinary pig, and both in Michigan (where also the Lake Superior Iron & Chemical Co., in which many British investors are interested, has several plants) and in Alabama in the South the industry is lagging. The companies interested have introduced elaborate and secret methods of utilization of the by-products from the charcoal kilns for the manufacture of drugs, and have hired German experts to direct their chemical works, which in some cases exceed in magnitude the iron-

making plants, but the returns have not been as great as was expected.

John T. Jones, of Iron Mountain, the inventor of a new process 'step-furnace' for "metallizing iron ore and increasing the iron content of ores," has transferred his experimental work to Marquette, where he will continue operations in the metallurgy of iron. It is understood that the Boston and Chicago men who are now financing Mr. Jones, under a new arrangement, include the Longyear interests. One of his previous backers was George St. Clair, of Duluth, mine-owner and operator. Mr. Jones began his experiments at Iron Mountain six or seven years ago, where he had a horizontal cylinder like a tube-mill, but much longer, which was slightly inclined and revolved slowly. Iron ore fed in the upper end mixed with gas from the distillation of coal which entered the lower end, producing a nodulized spongy product

CHARCOAL IRON BLAST-FURNACE OF CLEVELAND-CLIFFS IRON CO.,
MARQUETTE, MICHIGAN.

high in iron. Since then he has tried the furnace at the old Kloman mine at Republic, and with copper ores in the West. A fortune has been spent in overcoming the practical difficulties, of which the furnace lining has given the greatest trouble. The new plans call for a vertical stack instead of a horizontal cylinder. Mr. Jones has been assisted by his son, and he has worked very hard with the experiments. His friends and also the many people interested in low-grade iron ores are watching his results closely.

General Mining News

ALASKA

CHISANA

According to C. F. Boggs, who arrived in Cordova at the end of May, it is estimated that the season's clean-up will be worth \$500,000. C. Range has a steam thawing plant, and is recovering \$300 to \$500 per day from the mouth of Big Skookum creek. Dahl is getting from \$1.25 to \$2 per pan on Riolyte creek, three miles below the mouth of Bonanza. Sluicing is to be started on all claims from the mouth of Bonanza to No. 10, also on other creeks. There are about 600 men in the camp.

CIRCLE

Owing to the heavy run of ice and water in the Yukon river, the town of Circle was badly damaged about May 14.

FAIRBANKS

Warm weather during the second week in May allowed sluicing to be commenced on Fairbanks creek. The dredge had not started, but is expected to commence during June. James McGann recently arrived from the Kuskokwin district, described in this journal of May 30, after 'mushing' about 800 miles on foot. He stated that work there is quiet, and some parts are discouraging. On the afternoon of May 10, the ice broke up in the river at Fairbanks.

IDITAROD

Considerable damage was done by the break-up of ice in the Iditarod river on May 10, resulting in a flood and the burning of the Northern Commercial Co.'s warehouse.

KETCHIKAN

On Prince of Wales island, near Hollis, is situated the Ready Bullion mine, 295 ft. above sea-level. The orebodies are quartz in diorite and porphyry, and the vein being worked consists of 10 in. of quartz and 20 in. of altered porphyry, the latter averaging \$13 gold per ton. Work to date totals 2000 ft. A mill consisting of an 8 by 10-in. Blake crusher, five 1000-lb. stamps, amalgamating plate, and a concentrating table, driven by a 5-ft. Pelton wheel, recovers 90% of the gold content, the recovery being \$33 per ton. A Chilean mill and cyanide plant may be added.

NOME

Sluicing has been started on some of the claims, and winter dumps are being cleaned-up. There is a shortage of water so far, as the weather has been cold. The Bering sea was solid on May 25. The steamer *Corwin* had to discharge its cargo on the ice several miles from the town, from whence it was sledged to the beach.

SEWARD

The sale of 18,000 acres of ground for \$150,000 has been made by J. Murray, who has gone to the Cache Creek district, on the Kenai river. The new owners will install two dredges next season. Mr. Murray has ordered a dredge from San Francisco, which will be delivered at Knik this summer. It will then be sent in to Cache creek next winter.

ARIZONA

COCHISE COUNTY

At 1500-ft. in the Copper Queen property, the Sacramento orebody has been blocked out for 150 by 350 ft., all of which is of good grade sulphide. It has not been decided how to mine this ore. To prepare for the extraction of the Dividend top slice orebody, a large storage chute of concrete has been completed at 400 ft. in the Czar shaft. It is of a new design, in that it is funnel shaped from 200 to 400 ft., and 30 ft. above the bottom is a set of baffles which will break up and help to

dry sticky ore dumped into the chute. The test concentrating plant should be ready by the end of June.

GILA COUNTY

An experimental plant for the leaching of copper ore is being erected by the Miami Copper Company.

MOHICOPA COUNTY

S. H. Brockunier, of Nevada City, California, has just completed examinations of the Steele and Moore tungsten mine at Cave Creek, and the Ed. B. Williams tungsten mine near Kingman, Mohave county. The Pittsburgh Tungsten Mines Co. has purchased the Cave Creek property on the strength of Mr. Brockunier's report, which was based on six months development of the property. It is understood that a mill will soon be erected.

MOHAVE COUNTY

The annual report of the Tom Reed Gold Mines Co., covering 1913, shows that 48,110 tons of ore averaging \$24.09 per ton was treated, with 97.05% recovery. Operating costs of mining, milling, etc., were \$7.52, and other charges \$1.13, making a total of \$8.66 per ton. A winze is now down nearly 1000 ft. depth. In a drift on the 950-ft. level, the vein assays from \$20 to \$40 per ton. No. 44 dividend has been declared.

CALIFORNIA

AMADOR COUNTY

A station is being cut at 2350 ft. in the Fremont mine, near Amador City. At 2300 ft. the orebody is said to be developing well. Dividends totaling \$20,000 have been paid this year, and \$234,000 to date.

BUTTE COUNTY

Two boats of the Oroville Dredging Co. recovered \$2729 during the week ended April 30.

CALAVERAS COUNTY

As mentioned in this journal of May 16, the Royal mine has been sold by R. E. Whitcomb, who had an option on it, to Fordyce & Co., of Boston. The mine is developed to 1100

SURFACE PLANT OF ROYAL MINE.

ft., and has been favorably reported on by W. A. Farish, R. F. Wells, and other engineers. E. P. Jennings of Salt Lake City, recently examined the mine. A large tonnage of \$3 ore has been opened. Past returns from the 120-stamp mill show that 123,000 tons yielded gold worth \$455,690, or \$3.72 per ton. The new company will have a capital of 300,000 \$5 shares, of which 150,000 will be in the treasury. The accompanying halftone shows the surface plant of the property.

MODOC COUNTY

Six feet of ore assaying up to \$80 per ton has been cut in the Modoc mine, owned by Chicago people.

NEVADA COUNTY

A Paynter rock-drill tester, described in this journal of August 2, 1913, is being installed at the Empire mine.

SHASTA COUNTY

It is not possible to resume work in the Midas mine where a fire started at 1200 ft. several weeks ago. Blowers are to be installed to clear the mine of gas. The owner of the mine, W. H. Roberts, has sold it to the Victor Power & Mining Co., adjoining. Redding and San Francisco people have taken an option on the American mine, adjoining the Gladstone. James Doyle is to be superintendent.

SIERRA COUNTY

The Western Gold Mines Co. has been organized in Grass Valley to work the Eastern and Western Cross quartz claims on Kanaka creek, between the Tightner and Plumbago mines. Work is to start in a few days.

COLORADO

EAGLE COUNTY

According to the state mine inspector, John R. Curley, mining is dull. The Lady Belle and North Dakota properties, the principal producers of the district, are shut down awaiting installation of a mill that will enable the owners to ship a much lower grade of ore. The other mines are still being developed, but in none of them has any amount of shipping ore been found, although a number of them are now in favorable looking formations. Should the Lady Belle and Dakota companies erect a good mill, there is no doubt that a great deal of ore will be mined in the territory now under exploration, but until the mill is installed there will be but little mining done in the Brush Creek district.

GILPIN COUNTY

In the Bezzant mine, in Leavenworth gulch, on the 225-ft. level, there is 20 ft. of ore 2½ in. wide, containing from 0.5 to 20.37% uranium oxide, showing strong radio-activity by the electroscope. This mineral has apparently cut out the gold and silver content. In the east part of this level, 100 ft. from the shaft, a streak of rich sulphide ore with gold and silver has been opened.

Melting snow has resulted in several properties in the district being temporarily shut down.

TELLER COUNTY (CRIPPLE CREEK)

Gold production of the district in May is estimated as follows:

| Plants. | Tonnage. | Average value. | Total. |
|-------------------------------------|----------|----------------|-------------|
| Smelters, customs | 4,160 | \$55.00 | \$228,800 |
| Golden Cycle, company and customers | 31,300 | 20.00 | 626,600 |
| Portland, Colorado City | 9,800 | 22.00 | 215,600 |
| Portland, Cripple Creek | 19,600 | 2.57 | 40,372 |
| Stratton's Independence | 11,752 | 2.96 | 33,686 |
| Colburn Ajax | 4,000 | 7.75 | 31,000 |
| Gaylord-Dante | 1,500 | 4.00 | 6,000 |
| Wild Horse | 1,200 | 2.80 | 3,360 |
| Kavanaugh (Jo Dandy) | 1,900 | 1.30 | 2,470 |
| Free Coinage (estimate) | 625 | 3.00 | 1,875 |
| Isabella | 550 | 2.10 | 1,155 |
| Total | 86,387 | | \$1,190,918 |

This was a small increase over April. The Portland local mill treated 2000 tons more than any previous month, while there were increases at the Colburn, Gaylord, Wild Horse, and Kavanaugh mills. New mills are contemplated, but there is no construction under way at present. The total output of the Isabella property, lessees and company, was 1855 tons averaging \$1.00 per ton. The Elktion yield was 1125 tons. Dividend No. 87 of 30¢ per share, has been paid by the Golden Cycle company. The total for 1914 is \$270,000. The Vindictious

total output was about 3700 tons worth \$115,000. The main shaft is down 1800 ft. Lessees at the United Gold Mines produced about 900 tons averaging \$20 per ton. The property of the Cripple Creek and Gold Hill Tunnel & Development Co. has been sold to G. Diamond for W. H. Spurgeon for \$5780.

IDAHO

The U. S. Government has just offered for sale two tracts of timber on Lol creek, within the Clearwater national forest, aggregating 600,000,000 ft. of saw timber and 350,000 cedar poles, together with a considerable amount of material for piling, shingles, and posts. A large part of the timber is Idaho white pine, but the stands include yellow pine, lodgepole, spruce, western larch, Douglas fir, cedar, and white fir. The prices, which represent the lowest rates which will be considered for the saw timber, range from 50c. per 1000 ft. for Douglas fir, western larch, and cedar, to \$3.50 for green white pine. The prices of poles range from 5c. to \$2.40 each, depending upon the size. Full particulars may be obtained from the district forester at Missoula, Montana, or from the forest supervisor at Orofino, Idaho.

BLAINE COUNTY

The first shipment of ore from the Nan Aug mine, 12 miles from Hailey, has been received at Salt Lake City. Lessees have opened a shoot 180 ft. long, which averages 60% lead, 70 oz. silver, and \$4.50 gold per ton. K. C. Woolley is in charge.

SHOSHONE COUNTY

A bond and lease on the Handspike group of copper claims will probably be given to Cecil Murphy of Kellogg by the owners, the Little North Fork Copper Mining & Milling Co. The property is 12 miles above Enaville. A royalty will be paid on ore mined. Better roads are necessary for transport. Four sets of lessees are working in the Yankee Boy mine, on Big creek.

Shrinkage stoping will be started at the National copper mine, at Mullan, in place of the ordinary system as at present. It is then hoped that the 500-ton mill will be fully supplied.

Residents of Wallace now claim that results of the disastrous forest fires in northern Idaho in 1910 are being made evident in the changed flow from a watershed then burned over, which furnishes the water-supply of the town. This basin included an area of approximately 2000 acres, and was formerly well timbered with trees from 50 to 200 years old, according to Forest Service bulletins. These were almost wholly destroyed by the fires of 1910. From this watershed the city gets its supply, not only for domestic purposes, but also for the development of electricity for power and light, so that the maintenance of a considerable flow is essential to the city. It is stated that before the fires the flow of the stream at its lowest stages was never below 1000 miner's inches, the unit of measurement which has been used; but since the fire the records show that the minimum flow has fallen to about 250 miner's inches, and it is now necessary for the company which furnishes water, light, and power to expend a considerable amount of money each year in developing power from steam, and to use a considerable part of this power in pumping water. Records of the weather bureau at Wallace show that the precipitation for the years since the fire has been about normal for the region. This seems to demonstrate to the townspeople that the unevenness in the flow must be due to the destruction of the forest cover of the watershed, and not to any change in climate or precipitation. In view of the situation, the Forest Service has undertaken to reforest the denuded watershed. Some planting has already been done, and eventually all of the watershed which is included within national forest boundaries is to be reforested. The people of Wallace are taking an active interest in the work.

MICHIGAN**HOUGHTON COUNTY**

At the Calumet & Hecla smelter at Hubbell, No. 9 and 10 furnaces have been started, owing to increased production from the mines. The Mineral Range railway, which serves nearly all mines save the Quincy, Copper Range, and Calumet & Hecla,

VERTICAL PUMPING ENGINE AT CALUMET & HECLA STAMP-MILLS,
LAKE LINDEN, MICHIGAN.

hauled 373,040 tons of mineral products in May, compared with 302,760 tons in April and 391,240 tons in May 1913.

MONTANA**FERGUS COUNTY**

From August 27, 1912, to December 31, 1913, the Barnes-King Development Co. produced 49,726 tons of ore, yielding \$414,594. The net profit was \$129,906.

SILVERBOW COUNTY

Development in the North Butte mine is resulting in excellent returns. At 2400 and 2600 ft. the Edith May vein assays about 9% copper, with good silver content. The Snowball vein is improving steadily. At the Tuolumne the shaft is down 2475 ft. The zinc concentrating plant of the Timber Butte Milling Co., south of Butte, will start work in a few days. Its capacity is 450 tons per day, and it will treat ore from the Elm Orlu mine, adjoining the Black Rock mine of the Butte & Superior.

NEVADA**CHURCHILL COUNTY**

The report of J. A. Burgess, superintendent of the Nevada Wonder Mining Co., shows that 3730 tons of ore was milled during April with a total net profit of \$22,114. An extraction of 93.5% was made in the mill. Development totaled 660 ft. of driving, cross-cutting, and raising, and 207 ft. of shaft-sinking divided among three shafts. The Nevada Wonder shaft has reached a depth of 1339 ft., and sinking has been stopped for the present. The cross-cut on the 1300-ft. level is now being driven toward the vein, and has reached a point 122 ft. from the shaft. It is expected that the vein will be cut at about 350 ft. from the shaft. A new head-frame has been built at the Hidden Treasure shaft, and a small electric hoist installed. Cross-cutting will be begun at this shaft in a few days on the 700-ft. level for the purpose of prospecting the vein. Sinking is still in progress at the Wonder Extension shaft, which is down 477 ft. It is planned to sink this shaft to 800 ft. before cross-cutting to the vein. At this depth a connection will be made with the 1000-ft. level from the Nevada Wonder shaft.

ESMERALDA COUNTY

Ore from the Jumbo Extension is now being treated at the Goldfield Consolidated mill. In May, 2780 tons yielded a net profit of about \$20,000. The gross value of 922 tons from the Florence, in April, was \$29,914, of which \$15,398 was profit. About 850 tons was treated in May. Water at 1750 ft. in the Atlanta is too great for the present pumps to cope with, and work on the vein at that level has been suspended until larger pumps are installed in the Merger shaft. In the Sandstorm-Kendall mine, 344 ft. of development was done in May. Three cars of ore averaged \$45, \$57.70, and \$88.90 per ton, respectively.

HUMBOLDT COUNTY

A new goldfield has been opened at Haystack, west of Winnemucca, between the Western and Southern Pacific railroads. The name comes from a lone haystack-shaped 'butte' standing on the level desert. The place was discovered by R. D. Maxfield, who leased his five claims to W. J. Merryfield and others of Winnemucca. Rich ore was opened by the new owners, the Haystack Mining Co., and a shipment of 30 tons made. This Company has let several leases. Tiernan and Geiger have had assays up to \$37.20 per ton from their Grenada claims. Between 40 and 50 people are in the camp, including some well known Nevada miners.

LINCOLN COUNTY

A report on the Day-Bristol Consolidated Mining Co., of Pioche, has been filed in the district court by the receiver, H. E. Freudenthal. The following ore shipments were made: Company, January 1, 1913, to January 14, 1914, 6550 tons, worth \$15.84 per ton; Hillside lease, 125 tons worth \$19.04 per ton; Tempest lease, 84 tons worth \$28.21 per ton; Iron Mine lease, 308 tons worth \$15.78 per ton; and National lease, 258 tons averaging \$16.28 per ton. The report deals with wagon-haul costs, royalties, and other data.

Ore shipments from Pioche during the past fortnight amounted to 86 cars, of which the Prince Consolidated contributed 71 cars.

LYON COUNTY

The Mason Valley smelter received 4530 tons of ore during the week ended June 3, of which 1891 tons was from the Mason Valley mines, 1023 tons from the Nevada-Douglas, and 1616 tons of other custom ore.

NYE COUNTY

Nine mines at Tonopah produced 11,227 tons of ore worth a total of \$291,290, during the first week of June. At 1200 ft. in the Midway, the cross-cut has opened 4 ft. of good mill ore. At 600 ft. in the Desert Queen claim of the Jim Butler, a large tonnage of good ore has been developed. In May, the Extension mill treated 4673 tons, yielding 99,666 oz. silver bullion. At the Desert mill of the Tonopah Mining Co., 2759 tons of \$18 ore was treated during the week, with 92% recovery.

UTAH**SALT LAKE COUNTY**

It is said that another transport tunnel is to be driven into Bingham, starting from Pine cañon, a distance of 12,500 ft. This is expected to cheapen mining and ore transport to the International smelter. The cost would be about \$415,000.

WASHINGTON COUNTY

An extensive deposit of borax is reported to have been found in this county, and in the Arizona 'strip,' by prospectors sent out by F. M. Smith, of California.

WASHINGTON**STEVENS COUNTY**

Three wide veins are showing in the Security copper mine at Chewelah, of which L. K. Armstrong of Spokane is manager. A hoist and compressor have been installed. A party

of 75 Spokane mining and business men visited the Chewelah district last week. James A. Duff, mining editor of *The Spokesman-Review*, published an account of the work done there. The United Copper mill is treating 75 tons of ore per day, and crude ore shipments to smelters amount to 25 tons. One hundred men will soon be employed, and the output raised to 125 tons of milling and 75 tons of shipping ore. The raise to the 600-ft. level is through, and ventilation improved. The Copper King smelter made a trial run, but was stopped for repairs to the blower. No. 1 adit is in 1000 feet.

WYOMING

FREMONT COUNTY

The Atlantic City gold mining district is described in *Bulletin* 7, by L. W. Trumbull, the state geologist. The area was examined late in the fall of 1913. It is 24 miles south of Lander, which is a railway terminus. The average altitude is 7800 ft. above sea-level. Gold was discovered near South Pass in 1867. Considerable capital was attracted to the mines, but support was withdrawn. Since 1877, the district has not been prosperous. The rocks are generally schists, slates, and quartzites, with the later intrusives, andesite, diorite, and granite. The veins are all of quartz, found in schists, diorite, andesite, and granite. The Duncan is the only mine producing gold. The mill is described by D. C. Kelso, the superintendent. An all-sliming process is used at a cost of \$2.70 per ton. The estimated output of the district is \$4,137,000 from lode mines, and \$1,725,000 from placers. There are numerous relics of old stamp-mills and arrastres. Early milling was done without proper knowledge of the subject. Mining costs are low, but power costs are high. The Beck Milling Co. (Duncan mill) has installed a gasoline engine. Diesel engines could be worked, using oil from the Dallas field. Electric power may be obtained from the Boysen, or Popo Agie plants.

CANADA

ALBERTA

(Special Correspondence.)—Calgary is a live town since oil was found in the Dingman well at 2740 ft. The oil is very high grade, being from 60 to 64°B. The well gushed several times to about 40 to 60 ft. above the derrick floor, but this never lasted more than a minute at a time. There are about sixty oil companies operating now. Every store front is a broker's office, while shares are being dealt in on the curb. A number of stupid people have drawn their savings and speculated in companies whose holdings are anywhere from 2 to 60 miles from the producing well.

Calgary, May 20.

Automobiles are now successfully using the Dingman oil direct, it only being strained to clear it of sand before being charged into cars.

BRITISH COLUMBIA

New York people have bought the Golden Belle claims on Sheep creek. A number of other properties in the province have been sold. In April, Le Roi No. 2, at Rossland, shipped 1530 tons of ore and 168 tons of concentrate, returning \$20,884 for the quantity paid for. Expenses were \$21,100. The Van Roi, at Silverton, during April treated 2128 tons of 13.3 oz. silver, 1.9% lead, and 4.9% zinc ore, worth \$13,967. Expenses were \$14,448. The Surf Inlet mine, on Princess Royal island, is under option to the Tonopah-Belmont Development Co., of Nevada. It can be worked entirely by adits. The vein is from 10 to 50 ft. wide. There is plenty of timber and water power available.

ONTARIO

In order to remove the mud from Kerr lake, the sides will be washed clean by hydraulicking, water coming in by a 6-in. pipe. Trenching in the lake has revealed a 3½-in. vein for 75 ft., which assays up to 5000 oz. per ton. One unit of the Fountain Falls plant of the Northern Ontario Light &

Power Co. is in commission, and 1500 hp. is available for Cobalt. The plant contains 2 Morris water-wheels of 1500 hp. each, driving two 1250-kva. generators at 150 r.p.m. This Company has four stations supplying the Cobalt district. During the year ended April 30, the Buffalo Mines, Ltd., revenue was \$974,082. The net income was \$389,783; dividends paid, \$660,000; deficit, \$270,217; previous surplus, \$623,028; and surplus for 1914, \$352,811. Cash on hand in banks amounts to \$50,229.

Electric power for the Kirkland Lake district is now available from the Charlton plant. This consists of two generators of 545 hp each, driven by separate water wheels. The Tough-Oakes shaft is down 320 ft. At 220 ft. the ore-shoot is 220 ft. long. The Walsh claims, in Munro township, controlled by the Taylor syndicate, are said to have been sold for \$36,000. A report on the Dome Lake property during the first five months of 1914 shows that the shaft is down to 336 ft. At 300 ft. a cross-cut was driven to No. 3 vein, and an ore-pocket cut out at the station. At 180 ft. a cross-cut was driven 440 ft. to No. 1 vein, which shows good ore at other levels.

YUKON

During the week ended May 16 the Canadian Klondyke company's dredges recovered 1110 oz. gold. A heavy run of ice and water, the worst since 1898, passed Dawson on May 15, and did a good deal of damage on the waterfront.

KOREA

The May clean-up of the Oriental Consolidated Mining Co. produced \$169,000. In March the mills treated 23,550 tons, yielding \$172,932, with a profit of \$83,042. The Kuk San Dong mill was hung up the full time, there being no ore for it; also, for the same reason, the Candlestick mill only worked 23 days. In April the mills treated 24,123 tons, the Kuk San Dong being down for the period, yielding \$155,771. Recovery at the Taracol cyanide plant was 85%. The Okuras power-plant was stopped 12.83 hours, when the mills were driven by steam. There is plenty of water, but the Korean farmers want rain badly.

MEXICO

MEXICO

The Esperanza Mining Co.'s (American company) report for 1913 shows the following results:

| | |
|--|-------------|
| Ore mined, tons | 85,843 |
| Ore and tailing treated, tons | 207,442 |
| Value of yield | \$1,459,764 |
| Total profit | 491,232 |
| Dividends | 247,500 |
| Construction, exchange, etc. | 69,425 |
| Surplus to 1914 | 303,289 |
| Dividends paid by Esperanza, Limited (English company) | 206,400 |

The limits of the San Carlos vein are nearly known, and lower levels on the San Rafael vein have shown nothing profitable. Further prospecting is to be done. Ore reserves are estimated at 113,500 metric tons, containing a working profit of \$417,000. There is also 85,000 tons of possible ore in old workings. Tailing re-treatment should yield a profit of \$240,000.

SONORA

Operations at Cananea, according to latest advices, are gradually getting back to where they were before the recent shut-down and the exodus of Americans. Four or five blast-furnaces and both reverberatories are working. Miami concentrate is again being shipped to Cananea for treatment and is no longer going to Bisbee for smelting as it did during the shut-down.

Owing to favorable reports from the authorities in northern Mexico, the Mines Company of America may reopen the Creston-Colorado and El Rayo mines.

Personal

FRED J. POPE is at Douglas, Arizona.
 D. H. BROWNE is in San Francisco.
 CARL A. ALLEN is at Golconda, Nevada.
 C. W. MERRILL has gone to the Yosemite.
 J. W. MERCER has been visiting California.
 RALPH STOKES was in San Francisco recently.
 W. W. MEIN is expected in San Francisco, June 15.
 KARL EILEBS has gone to Europe for a summer holiday.
 W. W. CUTLER is at the Ridder Concession, Asiatic Siberia.
 CARL A. ALLEN is examining mining property near Golconda, Nevada.

J. P. LIPPINCOTT, of the Los Angeles aqueduct, was in San Francisco last week.

J. D. HUBBARD was given the degree E.M. by the University of Santa Clara, June 10.

C. B. LAKENAN, general manager for the Nevada Consolidated is in San Francisco.

R. A. CONRAD, of the El Favor Mining Co., Hostotipaquillo, Mexico, is at Trenton, Missouri.

F. E. PIERCE has left the service of the New Jersey Zinc Co. to open an office for consulting work in New York.

RALPH ARNOLD and HARRY JOHNSON are to examine the Flathead district of Alberta during the current month.

V. G. ZE FELD, associated with the Marshall interests in London, and until recently field manager in South Africa, is making an examination in northern Idaho.

OSCAR H. REINHOLT recently made an examination of a nickel prospect in the Coyote mountains and also inspected the Barrett dam-site for the city of San Diego.

W. A. THOMAS, who has had charge of sales of mining machinery for the Westinghouse Electric & Manufacturing Co., has resigned to take up practice as a consulting engineer in Pittsburgh.

FRANK M. SMALE, manager for the Portland Gold Mining Co., of Cripple Creek, recently visited the Coeur d'Alenes, Idaho, and Butte, Montana, for the purpose of investigating the economical electric haulage systems of those districts.

CHARLES F. RAND, president of The Spanish-American Iron Co., and past president of the American Institute of Mining Engineers, has been made a member of the Order of Isabella Catolica and decorated by the King of Spain with the Grand Cross of a Knight Commander.

Obituary

WILLIAM R. PERRIN, best known to mining men as the manufacturer of the Perrin filter-press, died at Chicago, June 2. Born in Indianapolis in 1860, he removed to Chicago before he was of age, and after some years spent in the stockyards established himself as a manufacturer of machinery in 1888. With branch works at Toronto, he manufactured for both the American and Canadian markets, but found time for active service in church, Y. M. C. A., and similar work.

ROBERT D. GRANT, born at Sunbury, Pennsylvania, in 1864, of Scotch parentage, died June 4 at his home at Los Angeles. In 1889 he took a position with the Parrot Silver & Copper Co., becoming general manager in 1899. He later became identified with the Sioux Consolidated group of mines in the Tintic district. In 1905 he formed the American Mines & Exploration Co. and later bought an interest in the Ray Consolidated Copper Mines of Arizona and led to the present development at Ray. In this he was associated with Seeley W. Mudd and Philip N. Wiseman. Mr. Grant was known as a successful mining man of the highest character and integrity and leaves a host of friends.

The Columbia branch of the AMERICAN INSTITUTE OF MECHANICAL ENGINEERS, the Spokane branch of the AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS, the Spokane branch of the AMERICAN SOCIETY OF CIVIL ENGINEERS, the engineering faculty of the UNIVERSITY OF IDAHO, and many engineering students of the University of Idaho met at Pullman, Washington, on May 16. Each section conducted a program. The program for the mechanical engineers consisted of papers by A. M. Balfour of Republic, N. C. Fassett of Spokane, P. S. Anderson of Spokane, D. C. Livingston of Dixie, Idaho, and C. H. Loux of Rossland, British Columbia. Mr. Moody, of Spokane, delivered a paper before the civil engineers, followed by discussion from the floor. R. S. Daniels and L. A. Lewis, of Spokane, and M. K. Akers, of the department of electrical engineering, delivered papers before the electrical engineers. A feature was the paper on 'Power Development Along the Spokane River,' by C. F. Uhden, chief engineer for the Washington Water Power Co., before the general session in the college auditorium, at which all the engineers were present.

The U. S. CIVIL SERVICE COMMISSION announces an open competitive examination, on July 13, for assistant mining engineer, for men only. Those passing this examination will be eligible to fill vacancies in the Bureau of Mines, for service in the field, in relation to coal mining or metal mining, at salaries ranging from \$1800 to \$2400 per year. The duties of these positions will include, in one case, investigations in relation to coal mines, and in another case in relation to metal mines, particularly such as concern the causes of mine accidents or waste in mining, and the suggestion of remedies therefor. It is desired to procure the services of persons having a broad training in mining, particularly underground experience.

The Metal Markets

LOCAL METAL PRICES

San Francisco, June 11.

| | | |
|---------------------|-------|-----------|
| Antimony | 9 | — 9 3/4c |
| Electrolytic copper | 15 | — 15 1/4c |
| Pig Lead | 4.15 | — 5.10 |
| Quicksilver (flask) | | \$38.50 |
| Tin | 39 | — 40 1/2c |
| Spelter | 6 1/2 | — 6 3/4c |

Zinc dust, 100 kg. zinc-lined cases, 7 1/2 to 8c. per pound.

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, June 11.—As will be seen by reference to the metal prices, there has been no change during the week. Copper is quiet, lead is firm, and spelter is dull. Business on the Stock Exchange in shares is about one-fifth of the total sold on the same day of last year. Unfilled orders of the Steel Corporation on May 31 were 3,998,160 tons, a decrease of 278,909 tons, compared with the end of April. Tin is strong at 31 to 31.25c., antimony is dull at 7.25 to 7.37c., and iron is quiet. Lead and spelter are dull at St. Louis, at 3.80 and 4.82 1/2c. respectively. In London, copper is quiet, tin is firm, and bar silver is firm at 26 1/4d. (52 1/4 cents).

SILVER

Below are given the average New York quotations in cents per ounce, of fine silver.

| Date | Average week ending |
|------------|---------------------|
| June 4 | 56.50 |
| " 5 | 56.12 |
| " 6 | 56.25 |
| " 7 Sunday | |

QUICKSILVER

Copper market for quicksilver is San Francisco, the goods being the largest producer. The price is fixed by the open market and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain slight reduction and those wanting but a flask

or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

TIN

New York prices control in the American market for tin, since the metal is almost entirely imported. San Francisco quotations average about 5c. per lb. higher. Below are given average monthly New York quotations, in cents per pound:

Monthly averages.

Tin statistics in May were as follows, as given by L. Vogelstein & Co. of New York: supplies of standard metal from all sources, 11,744 tons; deliveries of standard metal, 8876 tons; visible supplies, 19,465 tons, of which 5115 tons is in England, 2380 tons in Holland, 1841 on the Continent, and 1778 tons in the United States, while 4559 tons is in transit from the Straits, and 232 tons from Australia, the balance being afloat from other points. Average prices in May were 33.25c. per pound, New York, and from £156 15s. to £143 per ton, London. Visible supplies were 2868 tons greater than in April, and 4788 tons more than in May 1913.

COPPER

Quotations on copper as published in this column represent average wholesale transactions on the New York market and refer to electrolytic copper. Lake copper commands normally 1-5 to 1-1c. per lb. more. Prices are in cents per pound.

COPPER PRODUCERS' ASSOCIATION REPORT

The Copper Producers' Association statement for May shows a decrease in production and increase in stocks on hand. The details are as follows:

| | Pounds |
|---|-------------|
| Stocks of marketable copper of all kinds on hand at all points in the United States, May 8, 1914 | 79,337,000 |
| Production of marketable copper in the United States from all domestic and foreign sources during May | 142,308,287 |
| Deliveries for consumption, May | 55,592,179 |
| Deliveries for export, May | 74,710,477 |
| Stock of marketable copper of all kinds on hand at all points in the U. S., June 2 | 81,342,611 |

Recent changes in surplus have been as follows, in pounds:

| | Increase | Decrease |
|--------------|-----------|------------|
| May 1914 | 8,074,881 | |
| June | 1,061,619 | |
| July | 690,336 | |
| August | | 8,741,943 |
| September | | 2,773,288 |
| October | | 15,361,917 |
| November | | 15,569,138 |
| January 1914 | | 142,182 |
| February | | 8,924,823 |
| March | | 13,762,533 |
| April | | 7,168,582 |
| May | | 14,607,640 |

Copper consumption of Germany during the first four months of 1914 was 76,358 tons, of which 69,431 tons was imported from the United States.

Gold and Silver Transactions

Gold continues to be exported to Europe, and on June 10 the value sent to Paris from New York was \$6,500,000. There has been considerable competition in London on account of the demand for gold for European governments. Writing on May 28, Samuel Montagu & Co. make the following remarks:

"The outstanding feature is the cessation of the demand on behalf of the Russian Government, the chief competitor in the market for a long time past. A considerable amount of gold has been engaged in New York for shipment to Paris, the effect of which has been to prevent orders being sent to London. In the absence, therefore, of Continental inquiry, the Bank of England is likely to obtain the bulk of the bar gold, over £1,250,000, which arrived this week. The shipment to India was £162,000. During the week the net influx was £499,000. There were some further arrivals of sovereigns from Brazil, but these were intercepted and sent to the Continent. The imports of gold into Germany during the first four months of this year was about £3,380,000, and the exports about £595,000, making the net imports £2,785,000.

"Silver has been weak. In the absence of any support of consequence from those quarters whence buying orders usually emanate, prices continued to fall from point to point, until ground was reached at 25.94d. (51.88c.) for cash delivery on May 25. It is curious to notice that the same figure was touched momentarily on December 1, 1913, as a consequence of the final collapse of the Indian Specie Bank. On the recent occasion the price rallied ¼d. on the following day, a rebound much less sharp from that in December last. The improvement was continued, a further rise of ⅛d. being recorded yesterday, followed by a reaction of ⅛d. today. The primary cause of the collapse in prices has been the remarkable disinclination of buyers to enter the market, the entire absence of speculative interest, and unexpected large supplies from Mexico. The latter consisted of consignments probably considerably belated, which had been dispatched south from Mexico City by the railway which spans the isthmus of Tehuantepec and terminates at Coatzacoalcas, or Puerto Mexico, whence transport was made by steamer. As these consignments represented accumulations, the aggregate was substantial—rather too much, in fact, for so inanimate a market to face unexpectedly and to bear with equanimity. When the burden had been shouldered, the low level then reached provoked buying orders, with the result that prices responded sharply to the improved tone of the market. The stock in Bombay has decreased from £525,000 to £470,000. The offtake is rather less at 100 bars per day. The holdings in Shanghai by banks and others consist of £5,840,000, in 'sycee' or currency, an increase of £27,500. The holding of bars remains at about £38,000. No shipment has been made from San Francisco to Hongkong during the week."

SHARE TRANSACTIONS on the New York Stock Exchange in May totaled 4,685,762, against 7,068,338 in April, and 5,418,952 and 12,832,000 in May of 1913 and 1912, respectively. The value of bonds dealt in in May 1914 was \$43,404,000, compared with \$55,751,000 in April, and \$41,820,000 and \$60,500,000 in May of 1913 and 1912, respectively.

IDLE CARS in the United States and Canada total 241,803.

Company Reports

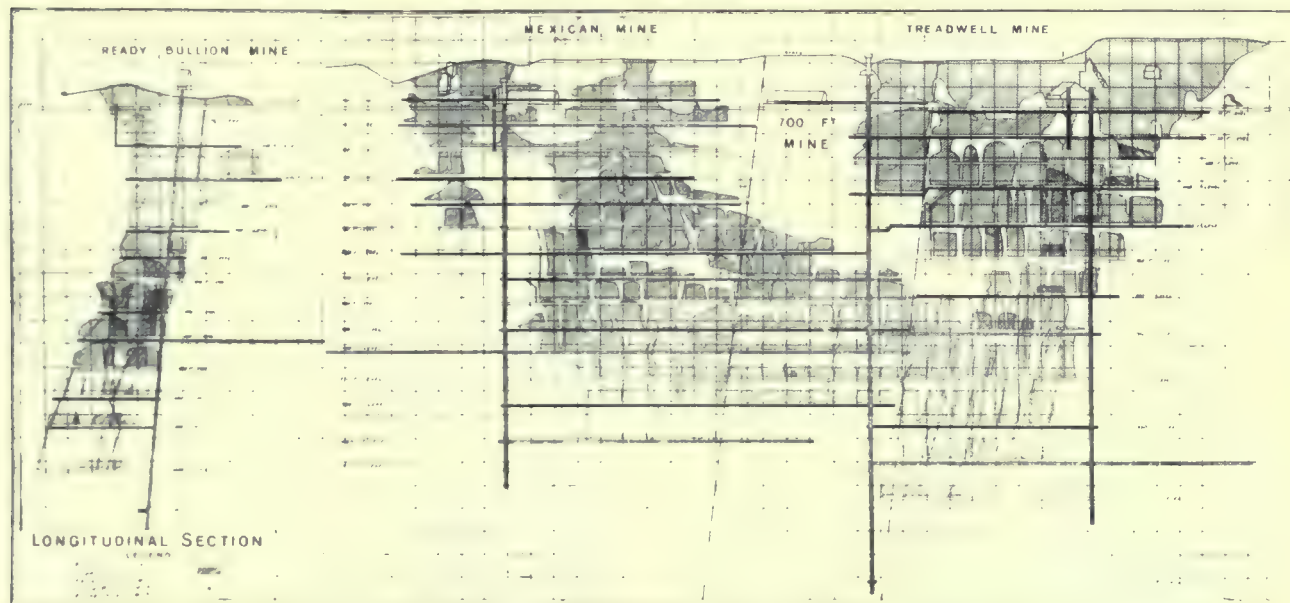

WALLAROO & MOONTA MINING & SMELTING CO., LTD.

This is a well known copper company operating in the state of South Australia, and the report is for the year 1913. In the Wallaroo mine, the shaft is now down to 2550 ft. The 2210 and 2430-ft. levels opened fair copper ore. In the Moonta mine a winze was sunk below 1200 ft. and a south drift from another shaft connected at 1440 ft. From the winze the 1320-ft. level was driven 185 ft. south, opening 4% ore. De-

South, Lower Contact, and Murray veins, the latter being the best shoot opened in the mine. While ore reserves are not estimated, the future of the property is quite satisfactory. A good deal of new equipment was added to the surface plant.

ALASKA MEXICAN GOLD MINING COMPANY ALASKA TREADWELL GOLD MINING COMPANY ALASKA UNITED GOLD MINING COMPANY

Reports for these well known Companies for 1913 are now to hand, and as they are all under the same control, and in charge of Robert A. Kinzie and E. P. Kennedy, general and assistant general superintendents respectively, the results of

LONGITUDINAL SECTION OF MINES ON DOUGLAS ISLAND, ALASKA.

velopment totaled 5257 ft. in both properties. Ore mined was 161,874 tons averaging 3%, sorted down to 60,649 tons of 8.54%, and 6421 tons of 12.29% ore. There was 52,789 tons of old tailing treated by leaching producing 965 tons of 78.3% copper precipitate. The smelter treated 70,671 tons of mixed ores, matte, and precipitate, producing 7112 tons of refined copper, 2161 oz. gold, and 1000 oz. silver. The flotation process gave a high recovery on old tailing, leaving a residue of 0.3% copper. Costs were \$5.60 per ton for mining, \$1.42 for ore dressing, 25c. for transport, \$1.98 for smelting, and 18c. for general expenses. The year's profit was \$259,000, and \$268,000 was paid in dividends. The surplus is \$787,000.

TONOPAH EXTENSION MINING COMPANY

This Company has declared a dividend of 7½c. per share, amounting to \$70,750, payable on July 1. Results during the year ended March 31, 1914, are as follows:

| | |
|--|-----------|
| Ore treated, tons | 58,022 |
| Silver output, ounces | 760,412 |
| Gold output, ounces | 8,070 |
| Average value of ore per ton | \$ 12,008 |
| Revenue from bullion | 615,780 |
| Cost of mining and milling, etc. (\$8.953 per ton) | 519,501 |
| Profit, including rents, etc. | 97,839 |
| Depreciation | 17,440 |
| Net profit | \$ 80,399 |

According to the general manager, John G. Kirchen, development amounted to 16,091 ft., making a total to date of 77,770 ft. Mining costs were increased 45c. per ton by the large tonnage completed, this cost being \$5.78 per ton. Work has been done to 950 ft. Ore was extracted from the North,

the past year are suitably reviewed together. The reports are complete in every detail of mine development, mill work, labor costs, and mine plans. A central hoisting shaft is being prepared in the 700-Ft. Claim for all the mines, as referred to below.

Development in the Mexican to 1460 ft., totaled 1668 ft., also several thousand feet of diamond-drilling in greenstone, slate, diorite, and schist. As soon as the 2100-ft. level from the Central shaft has reached the orebody, a drift will be turned east and continued through Mexican ground, and in the future, all ore developed and stoped from this level will be trammed to and hoisted through the new shaft. When at the surface, this ore will be crushed and distributed to the mills by the electric haulage system which is now in operation at the Central shaft. On the 660, 990, 1100, 1210, 1320, and 1460-ft. levels of the Mexican mine 1685 samples taken averaged \$2.80 per ton. Ore reserves below 1100 ft. amount to 430,939 tons in place and 385,943 tons broken in stopes. The total of 816,882 tons averages \$2.53 per ton, against 1,040,631 tons of \$2.75 ore in the previous year. At a point in the main east drift of the Ready Bullion mine of the Alaska United company, 1324 ft. from the east end line of the Mexican mine, a concrete bulkhead has been built, so that in case of fire, flood, or other emergency, it could be closed, thus preventing water or gases going from one mine to another. It is hitched 30 in. into the solid rock, and is 12 ft. thick of reinforced concrete. Through the centre a 24-in. opening was made, which can be closed automatically by a heavy cast iron door if there is a pressure of water on either side. The cost was divided between the two companies.

In the Treadwell mine, development to 1750 ft. totaled 4893

ft., also 3482 ft. in the United company's 700-Ft. Claim down to 2100 ft., including 330 ft. of shaft work. As was explained in the report for 1912, it is the intention to leave a solid pillar of ground between the 1750-ft. level of the Treadwell mine and the top of the stopes from the 2100-ft. level. The work of opening the latter level has been started from the Central shaft, three shifts being employed. This shaft is down 2271 ft. On the 600, 750, 1250, 1450, 1600, and 1750-ft. levels, 3815 samples were taken, averaging \$3.29 per ton. Ore reserves amount to 4,978,759 tons in place, and 1,114,549 tons broken in stopes, a total of 6,093,308 tons averaging \$2.67 per ton, against 6,977,958 tons worth \$2.72 in 1912.

The Alaska United operates the Ready Bullion and 700-Ft. Claim mines. In the former, development to 2200 ft. totaled 3997 ft., also several hundred feet of diamond-drilling in chloritic schist, diorite, black slate, calcite, and greenstone. The main shaft is 2326 ft. deep on the incline. On the 1350, 1500, 1650, 1800, and 2000-ft. levels, 1760 samples were taken averaging \$3.29 per ton. Ore reserves are estimated at 1,433,334 tons in place, and 275,328 tons broken in stopes, a total of 1,708,662 tons worth \$2.91 per ton, against 1,721,521 tons of \$2.82 ore in 1912. In the 700 Ft. Claim, 5418 ft. of work was done, mostly by the Treadwell company, also 274 ft. of drilling in slate with narrow dikes of diorite. The Central shaft was sunk 330 ft. in waste. A total of 2116 samples was taken averaging \$2.82 per ton. Broken ore in stopes amounts to 275,660 tons, and 1,005,815 tons in place, assaying \$2.46 per ton, against 1,154,273 tons worth \$2.63 in 1912.

Results of the three Companies are best shown in tabulated form:

| | Alaska Mexican. | Alaska Treadwell. | Alaska United. |
|---|--------------------|----------------------|-------------------|
| Stamps working | 120 | 540 | 240 |
| Ore crushed, tons | 227,112 | 886,957 | 448,427 |

On October 11, 1913, a fire started in the head-frame and

crusher-house of the Treadwell mine, and in spite of 11 streams of water under 200-lb. pressure, the structure was destroyed. The Central plant has since handled all of the ore. A number of primer houses were used at the various mines, but a central house was built to minimize accidents, and save cost in handling explosives. The second unit of the Nugget Creek hydro-electric plant was started. It consists of a 2350-kva. Westinghouse alternating-current generator; 60-cycle, 3 phase, and 0.85 power factor, driven by a 3800-hp. Pelton-Doble double overhung type tangential water-wheel running at 300 revolutions per minute.

CROWN RESERVE MINING COMPANY, LIMITED PORCUPINE-CROWN MINES, LIMITED

The Crown Reserve company operates at Cobalt, and controls a gold mining company, the Porcupine-Crown Mines, Ltd., at Porcupine, Ontario. The report covers the calendar year 1913. The general manager, Samuel W. Cohen, reports the following as to the Crown Reserve: development amounted to 5345 ft.; stoping, 394,489 ft.; and ore broken, 56,982 tons. The Carson vein, a heavy producer of silver, maintained its size, but metal contents were low. From the 200-ft. level the Gear vein No. 14 produced 500,000 oz. Development was promising. High-grade ore was opened at 100 and 150-ft. on No. 17 vein, and a raise from 100 ft. for a height of 62 ft. broke into the bottom of Kerr lake, which had been drained. Rich ore was opened throughout the raise. Stoping on Ross vein No. 24 produced 325,000 oz. Work on No. 29 vein proved a good length at 200 ft. The North vein has not proved very valuable. No. 2 vein is one inch wide at 100 and 150 ft., and produced 135,000 oz. Other prospecting was promising.

The Dominion Reduction Co. treated 29,543 tons of milling ore for the Company, averaging 17.71 oz. per ton, at a cost of \$4.23 per ton, or 23.81c. per ounce. Shipments of ore were 313 tons containing 1,138,896 oz. The total yield was therefore 1,776,678 oz. worth \$1,056,272. The average price received for silver was 59.45c. per ounce, while the cost was 23.02c. per ounce. The mine profit was \$647,316. Balance from 1912 was \$821,393; net profit from silver mine, \$528,288; net profit from Porcupine-Crown Mines, \$308,877; and interest, \$9336; making available the sum of \$1,667,894. Dividends paid were \$795,966, and after deducting costs of the Silver Leaf lease, the surplus is \$844,616.

In the Porcupine-Crown Mines company, the Crown Reserve holds 60% of the shares. The manager, Maurice W. Summerhayes, reports as follows: In the mine, work amounted to 3411 ft., making 5922 ft. to date; stoping totaled 142,643 cu. ft.; and diamond drilling was 2739 ft. Costs of prospecting were 60c.; development, \$1.17; and ore breaking, \$2.11 per ton. On the 200-ft. level the ore-shoot is 465 ft. long, averaging \$35 per ton over 4 ft. At 200 ft. it is 570 ft. long; at 300 ft., 610 ft. long; 218 ft. of \$30 ore over 4 ft. at 400 ft.; and a winze sunk below the latter level opened 5 ft. of \$70 ore. Ore reserves are estimated at 72,472 tons assaying \$25.66 per ton.

During the year, 15 stamps and cyanide plant were added to the existing 5-head mill. Tests showed that the Dorr continuous decantation process was the best for the ore. The plant started in November, and has been treating 100 tons per day, with 96% extraction, at a cost of \$1.50 per ton. During 1913 the original and completed plant treated 19,754 tons of ore averaging \$20.30 per ton. Save for the last six weeks of the period, treatment consisted of amalgamation only, which saved 85 per cent.

The revenue was \$275,039, and operating profit \$150,573.

ALGOMAH MINING COMPANY

This Company is opening a mine in Michigan. Development was in progress in 1913 until the strike in July caused a shut down. The main shaft has reached a depth of 415 ft. During 1913, \$22,500 was spent on development. The assets of the Company are given in the balance-sheet at \$855,000.

Book Reviews

EXCAVATING MACHINERY. By Allen Boyer McDaniel. McGraw-Hill Book Co., New York. P. 326. Index. For sale by the *Mining and Scientific Press*, San Francisco. Price \$3.

This is an exceptionally comprehensive work dealing with an interesting phase of engineering construction. The author has treated his subject in ten chapters and two appendices, each chapter being devoted to one specific type of excavator. In addition to discussing the structural details, peculiarities of design, and correct application of each, the author has succeeded in compiling a great deal of data concerning the actual use of each in various localities. A quantity of cost data is given in each case which adds very materially to the value of the work. This is one of the best works of its kind that has come to this desk and will constitute a valuable addition to the libraries of all engineers and contractors.

AMERICAN ELECTRICIANS' HANDBOOK. Compiled by Terrell Croft. McGraw Hill Book Co., N. Y. P. 692. Index. For sale by the *Mining and Scientific Press*, San Francisco. Price \$3.

This work is intended especially for practical electrical men, wiremen, contractors, linemen, superintendents of small plants, operators, and construction engineers; in short for the type of man who is called upon to install and use the apparatus that has been designed by the electrical engineer. The preparation of the subject matter has been a process of compilation, the greater part of the data having been taken from the notes of the compiler. Many abstracts are given from standard books and from technical magazines. Theoretical questions have been avoided as much as possible, the data presented being confined entirely to established practice as it existed up to the time of publication. The subject matter is divided into six sections under the general headings of Fundamentals, Generators and Motors, Outside Distribution, Interior Wiring, Transformers, and Illumination.

ELEMENTS OF WATER BACTERIOLOGY. By S. C. Prescott and C. E. A. Winslow. P. 318. John Wiley & Sons, New York, 1913. For sale by the *Mining and Scientific Press*, San Francisco. Price \$1.75.

The book was originally prepared in 1904 for students of biology and sanitary engineering at the Massachusetts Institute of Technology. To cover advances in the science it was revised in 1908. Because of further advances and because of the publication in 1912 of the revised edition of 'Standard Methods of Water Analysis' by the American Public Health Association, the third edition has been prepared.

The book is a very satisfactory and modern treatise on water bacteriology. This is especially true with respect to sanitary water analysis. The recent recommendations of the Committee on Standard Methods are discussed. The authors do not agree with the recommendations of the Committee that the 27 count should replace the 20 count, but agree with the resolution adopted by the Laboratory Section of the American Public Health Association at the Washington meeting, that both determinations should be made in ordinary routine water examination.

The chapter dealing with the isolation of pathogenic bacteria dwells especially on the recent methods for the isolation of typhoid bacilli. The authors believe that the whole group of lactose-fermenting bacilli is significant and that the lactose-fermentation test is sufficient identification of the coliform group for ordinary sanitary purposes. The specific identification of *B. coli* is therefore not necessary in routine tests. A new chapter dealing with the sanitary study of shellfish has been added. The book as a whole is a very satisfactory treatise, valuable both to the student and to the practitioner in the field of water bacteriology. E. B.

Industrial Progress

Locomotive Cranes

Among the machines and appliances which not many years ago were looked upon as superfluous and as having a limited application, but which today have come to be recognized as standard equipment in the conduct of large scale mining and smelting operations, the locomotive crane may be prominently mentioned. This machine, which is fast finding favor among the operators, has been adapted to various uses by the miner and smelterman and has proved itself to be a great labor saving and cost reducing machine. In construction work the crane supplies an efficient means for the handling of machinery and materials and after the smelter or mill has been completed, the crane is employed for the handling of supplies and products. In the handling of ore in open-cut mining operations the locomotive crane is invaluable for lifting

LOCOMOTIVE CRANE IN OPERATION.

drills, handling broken ore and waste, lifting cars, and moving supplies. In bench operations the crane is well adapted for the transfer of drills, supplies, etc., from one level to another. In the illustration is shown an Ohio locomotive crane used for reclaiming and loading.

With the increased use of cranes of this type the requirements have become more exacting as to material and adaptability. The breakages in parts usually involved castings and materials of fragile nature, which resulted in delays and cessation of work while repairs were being made. This objection was increased by the manufacturers frequently charging heavily for any repairs or spare parts, which led to no little dissatisfaction. The modern crane has been modeled and built with the object of simplicity in design and durability in construction, providing accessibility to all parts of the machinery and representing such construction as will render the crane almost immune to injury with ordinary care. In the Ohio crane this feature has been given careful attention, and in order to make it as immune to injury as possible steel castings are employed where gray iron castings are the ordinary practice.

The capacity of a locomotive crane is based upon the maximum safe working load which the crane can handle at a 12-ft. radius; that is, horizontal distance between the crane's axis of rotation and a perpendicular line through the centre of the hoisting hook or grab bucket, as the case may be. The cranes are built for standard-gage railroad track, 4 ft. 8½ in.,

but wider gage may be had if so desired. The main base of the Ohio is one large steel casting, this being used to avoid breakage and the common annoyance from loose bolts. The turntable revolves upon four bevel steel rollers of large diameter. The steel track upon which they operate is 8 ft. diameter. In that the machine is very heavy, counter-weights and scrap iron ballast are dispensed with.

Vertical tubular boilers are used and the engines are of the horizontal double cylinder non-reversing type. The cylinders are jacketed with magnesia blocks which are covered with sheet steel. The boom is of structural steel and operated by a heavy bronze worm gear keyed to the boom drum shaft and engaging a steel worm with heavy turned threads. Cast iron sheaves, plow steel rope, steel fall-blocks, cast iron drums, bronze bearings, forged steel shafting, cone friction clutches, foot brakes, steel gear, compression grease cups, oil cups, wells, and channels are all given careful attention in locomotive crane construction with the result that the finished crane is adapted to meet the hardest of working conditions. The Ohio Locomotive Crane Company at Bucyrus, Ohio, represented on the Pacific Coast by the Edward R. Bacon Co., San Francisco and Los Angeles, is producing what is claimed to be one of the most modern types and one which embodies the results of years of experience in crane construction and design.

The GENERAL ELECTRIC CO., of Schenectady, New York, is supplying the Alaska Gastineau Mining Co. at Sheep creek, Alaska, with 35 additional motors ranging from 7½ to 300 hp. The Anaconda Copper Mining Co., Butte, will install 23 additional induction motors ranging from 5 to 20 hp., with starting compensators and 10 oil switches. The Tomboy Gold Mines Co., Telluride, Colorado, will place in operation in its mines a 4-ton electric mining locomotive which was recently purchased from this Company. The Arizona Copper Co., at Clifton, will add to its electric equipment at 150-hp. induction motor and two 3-bearing 17½-kw. motor-generator sets. The Anaconda Mining Co., Butte, Montana, has purchased for installation in the plant of the International Smelting & Refining Co., Miami, Arizona, two 200-kw. 3-bearing synchronous motor-generator sets. The Alaska Treadwell Gold Mining Co. has ordered three additional 75-hp. induction motors with compensators. The Champion Copper Co., Painesdale, Michigan, will place three new 4-ton electric mining locomotives in operation at its plant, all of which equipment is being supplied by the General Electric Company.

MORSE BROS. MACHINERY & SUPPLY CO., of Denver, has recently purchased the entire stock of machinery and supplies of J. H. Wilber, the largest machinery dealer in Cripple Creek, Colorado. This purchase consists mainly of hoisting engines, boilers, compressors, drills, steel, and all articles used in and about a mine. It has also purchased the tunneling plant of the Karns Tunneling Machine Co., at Magnolia, Colorado, consisting of Imperial type air-compressors, boiler, rail, pipe, etc. This plant was only in use about three weeks. A complete 100-ton cyanide plant, crushers, rolls, steel cyanide tank, etc., at Creston, Colorado, known as the Loungridge mill, has also been purchased. This mill was in operation less than sixty days, was completely equipped with electrical drive, electrical generator station, and the material practically new.

The HARDINGE CONICAL MILL CO. is in receipt of a 'repeat' order for two 8-ft. Hardinge mills from the Caucasus Copper Co. of South Russia; also for two 8-ft. mills for the Spassky Copper Co. of Russia.

New bulletins of the CHICAGO PNEUMATIC TOOL CO. include No. 152, 'Chicago Galting Drills'; No. 153, 'The Chicago Sinker'; No. 154, 'The Chicago Stoper'; No. 172, 'Chicago Plug and Feather Drill'.

STEAMSHIP disasters, such as the sinking of the *Empress of Ireland* come home to us when we learn that among those lost were personal friends, and men in many lands have been saddened by the knowledge that among those lost in the *St. Lawrence* were A. E. Barlow and his wife. Canada has produced a select group of tireless and fearless explorers who have been more than mere traversers of the wilderness; men who join to physical courage the knowledge and insight of the scientifically trained. Among them Barlow ranked high. He not only went through the wild places of the earth, but he brought back knowledge that served as the basis of industry, and among geologists and mining men his loss will be felt keenly.

MINERAL PRODUCTION in Mexico is decreasing rapidly. The figures for the present fiscal year reflect the unsettled state and the trying conditions through which the country is passing. It is disheartening to record a decrease in production of over \$53,000,000 for the first eight months of the present fiscal year. In the general decline over this period the gold exports dropped \$9,041,961, silver \$30,007,376, and copper \$17,961,101, according to statistics compiled by the Mexican government. Oil is the only mineral product which shows an increase, the exports for the period under review totaling \$12,612,569 as compared with \$6,543,688 for the corresponding months of the preceding year. The recent activity of the Constitutionalist forces in the vicinity of Tampico will no doubt occasion a decline in the petroleum output, although it is to be noted that no wanton destruction of property has occurred in the oilfields nor does it seem likely to occur.

THE DEUTSCHEN PLATINWERKE meeting held at Düsseldorf was the occasion for the reading of a report upon the Westphalian platinum deposits, noted in our issue of January 31, 1914, by Mr. W. Himmelfarb of the Clausthal mining academy. It is pointed out that the platinum occurs with lead, zinc, antimony, and nickel, and not in a colloidal state as previously supposed. As evidence of the successful treatment of these ores by a new process, there was exhibited a 500-gram bar of platinum. This bar resulted from the treatment of 25 tons of ore. One ton of concentrate from the 25 tons of ore also yielded about 11

per cent nickel. Mr. Hommel estimates that the cost of production, including mining, will be about \$4.80 per ton. As the world's platinum production is at present entirely from alluvial deposits, the Westphalian deposits of platinum *in situ* have been generally regarded with extreme skepticism. It will be interesting to note what effect, if any, this evidence of an important new field will have upon the industry. If the large bodies of ore assaying 5 grams platinum are highly profitable, as claimed, it would seem that a part solution has been found at last for the problems due to ever-increasing cost of the metal and decreasing sources of supply.

CANADIANS are even more excited than the Japanese over recent petroleum discoveries, and there is an oil 'boom' on at Calgary that rivals Beaumont days. The new Dingman well has not yet been tested, and California men look wise when they see the 1000-gallon (not barrel) tank that has been provided to receive and store the oil when the pump starts. However, the oil is of high grade, 64.2 Baumé, and there is a strong flow of gas, estimated at 2,000,000 cubic feet. Our Toronto correspondent summarized last week the report upon the area by Mr. R. W. Brock, a most competent and cool headed observer. This may be supplemented by stating that at 2000 feet the well would be near the bottom of the Judith river. This formation consists of fresh-water sediments and contains thin coal beds. Beneath it is the Clagget, which, in Montana and south of the international boundary, contains considerable organic matter. Still lower is the Benton shale, which in Colorado and northward has yielded oil at a number of points. The Calgary oil is of such exceptional high grade that it is best interpreted as a diffusion product produced by migration from some underlying body of crude oil. So far it offers encouragement to drill further, though the probability of a big supply in the Dakota sandstone has been overestimated by our friends of the North, if experience in the United States is a guide. The particular anticline being tested at Calgary indicates a field about 700 feet wide and three to ten miles long. The geology of the region suggests additional areas for prospecting, but on the whole, we think the farmer who traded 80 head of cattle for a receipt for stock to be issued in a company still to be formed, without learning whether the particular land to be prospected was 10 or 30 miles away and over anticline or syncline, was a trifle precipitate; just a trifle.

VOLUNTARY ARBITRATION is proposed by the United States Commission on Industrial Relations, which has submitted a tentative draft for a bill creating a national board of mediation and conciliation to deal with strikes and lock-outs in any part of the country that seems likely to involve the federal government. The bill expressly denies to the board any compulsory powers of arbitration or prohibition of strikes. It thus avoids conflict over any question of

state or interstate jurisdiction. Within the past year Congress has been called upon to investigate strikes in the states of West Virginia, Michigan, and Colorado, and precedent for a federal board is found in the Anthracite Coal Strike Commission of 1902 which settled difficulties in Pennsylvania. All efforts at conciliation in recent strikes have failed, and if the federal government is compelled to intervene after a crisis has been reached, it is better that it have a permanent board representing the entire nation and having the confidence of both employers and employees, which board can be asked to intervene at the inception of such disputes. The bill is modeled after the plan of the Newlands act creating the present board of conciliation and mediation for dealing with railway disputes. The success of the Newlands act in the railway field suggests that a similar agency might avoid other strikes, or at least prevent them reaching that state of violence which has become so common. Strikes have become an all too frequent source of disturbance in mining, and their results have in most instances been so unfavorable to both employee and employer that sane arbitration of the differences between capital and labor should be welcomed by both.

China's New Mining Regulations

Many of our readers will remember that in the treaties which were made following the outbreak in 1900, it was specified, among other things, that China should prepare a code of mining regulations which would permit foreign capitalists to enjoy the same rights in China as they do in other countries. This was especially provided in the Mackay treaty of 1902. In carrying out the terms of this treaty, delay after delay has occurred. Sets of regulations have been drawn up by bureaus at Peking and submitted to the representatives of the treaty powers, only to be rejected. In the latest reorganization of the government at Peking, Chang Chien has been appointed Minister of Commerce and Industry, and has created a Bureau of Mining, of which D. T. Yang is the head, and the distinguished director of the Geological Survey of Sweden has been appointed adviser to the Mining Bureau. Minister Chang has exhibited a great deal of interest in the development of the mineral resources of China and has given out various suggestions as to their development. Among others, a new set of mining regulations has been drawn up. These have to be submitted to the treaty powers, but they are so much an improvement over any that have previously been composed that they stand some chance of being sanctioned. The regulations are too detailed and require too much space to give in full, but it will be worth while to summarize some of the most important features.

Chapter I covers general rules and provides that citizens of the Republic of China may secure mining rights, and citizens of foreign nations may also secure

them when doing joint business with citizens of China. Foreigners wishing to engage in mining must present to the Director of the Mining Supervision Office a certificate by their consul showing that they are willing to abide by Chinese mining regulations. Salt and petroleum are reserved as government monopolies, but the various other kinds of mineral substances are open to general exploitation. In the case of coal, metals, and precious stones, the mining rights are separate from the ownership of the land. In the case of the non-metallic minerals the ownership of the mining rights goes with the ownership of the land.

Chapter II defines areas on which mining may be conducted. As in all previous regulations, it is provided that mines may not be opened in close proximity to tombs, temples, fortifications, and public utilities without permission. The distances, however, are much decreased, a maximum of one-third of a mile now being the rule. It is provided that the claims shall be bounded by vertical planes. A coal-mining area is allowed a minimum of 54 acres and up to 1180 acres. The areas allowed for other mines vary between 10 acres and 540 acres.

Chapter III deals with mining rights. This contains a great many clauses, and is rather complex. It is interesting to note that the petitioner for a mining area must prove that the area for which he applies does contain the mineral which he wishes to exploit. Provisions are made for conflicts and also for the exploitation of two different minerals in the same area by different groups. Where more than one person applies for mining rights for the same area, they must be given to the first applicant. There are possibilities for a good deal of difficulty in the regulations. Thus, for example, Article 20 says "mining rights should not be surrendered to others in part." What effect this might have on the sale of stock in a mining company is open to question. Similarly, Article 44 says that the operators of mining enterprises "should from time to time submit the working plans, drawings, and explanations, to the Director of the Mining Supervision Office for decision. The possessor of the mining right shall operate the mines according to the plan and description passed by the Director of the Mining Supervision Office. With regard to the plan and description for the above, no change shall be made without the approval of the Director of the Mining Supervision Office."

The presence of such a trouble-making clause in the regulations is, of course, clear evidence that the persons who drew them up are without any competent knowledge of mining. It would be entirely impossible for any government bureau to undertake the detailed supervision of the work of operating every mining company in China. The greatest difficulty, aside from the delay which might be entailed by an attempt to enforce this clause, is the fact that neither the Minister of Commerce nor the present head of the Mining Bureau has any knowledge of mining whatever. Mr. Yang being a graduate of a law school in Japan,

and it is highly probable that such a condition is likely to persist. The difficulties of a company which tries to secure approval of its plans from officials who know nothing of mining are easy to imagine. The mining right may be canceled if the operations are not conducted with reasonable diligence, if the tax is not paid, or if suitable precautions for the safety of employees and the public are not followed. It may also be canceled "if the plans and descriptions submitted are not followed" or "if the mining enterprise injures the public interest." It is evident that these last two provisions open a fertile field for the oppression of mining operators by the officials, and, indeed, the whole series of regulations have the air of being drawn up more with the idea of developing 'squeeze' than of developing the mineral resources.

Chapter IV deals with the land used for mining purposes and provides that the proprietor of the mine may, under proper regulations, use the land of others in order to carry on his own necessary operations. An adequate security may be demanded by the owner of the land for any such use of his property. Chapter V deals with miners, their duties, wages, compensation, injury, and so on.

Chapter VI deals with mining taxes. It provides for two classes of tax: on the area and on the output. The area tax for metal mining amounts to \$0.45 per acre per year. This is in addition to the ordinary land tax, which is paid everywhere throughout China. On the product of metal mines, $1\frac{1}{2}$ per cent of the market price at the mine shall be collected as tax. For non-metallic minerals, 1 per cent is collected. The regulations do not clearly explain whether the tax is on the gross or net value of the output.

Chapter VII covers provisions for policing the mines, and it similarly contains clauses which might lead to a good deal of difficulty on the part of the operator. Thus article 86 provides that the Minister of Commerce or Director of the Mining Bureau may demand the employment or change of experts employed by the mine operator. Chapter VIII deals with judgments, complaints, and lawsuits. Article 93 provides that if foreign citizens in partnership with Chinese citizens in mining affairs have any dispute, the case must be settled by the decision of the Director of the Mining Supervision Office. It is scarcely probable that in the present state of government in China the treaty powers will agree to any such stipulation as this.

Chapter IX deals with punishments for violations of the provisions of the regulations, and closes with a provision that contracts and agreements previously made for the raising of foreign capital shall continue in force according to the conditions under which they were made.

While on the face of it the new regulations look much more favorable than any that have so far been proposed, as a matter of fact they fall a long way short of leading in any practical degree toward the adequate development of Chinese mineral resources through the aid of foreign capital.

The Miner As A Pioneer of Civilization

By T. A. RICKARD

It is a common saying that agriculture and mining are the two basic industries. When man rose above the brutish individualism of his primordial state and began to develop the social instinct, he turned to the soil, in order to win food for his family. He paused in his migration; the soil held him; it gave root to his rudimentary community; it gave him the chance to enlarge his energies. His tracks became highways; his rivers, avenues of trade; and as his traffic expanded, so his imagination widened, until, out of the crudities of communal development grew the complexities of civilization.

But the nomadic habit lingered; the spirit of the hunter survived in man: a wanderer and a wonderer he stood beneath the starry dome or the forest arch not knowing whether he were a guest or a captive in the domain of Nature. The hills beckoned; the seas called; the more venturesome left the tents of the tribe in search of material wherewith to fashion their implements. They sought iron for weapons, copper for tools, gold for ornament, and found them in various guise in the earth under their feet. They became miners. To those who delved successfully came power. Throughout the ages the more energetic and adventurous broke from the plough and forsook the cattle in order to explore and to exploit. They furnished the metals from which the artificers fashioned engines of power and machines of intelligence. They won the materials for a social structure that, based on stone and built in iron and copper, soared in many-storied tracery of steel to towers radiant with light and vibrant to the sky—towers so far above the common ground that man almost forgot his lowly origin and claimed kinship with the stars.

Basis of Civilization

Civilization was developed on a metallic basis, not as regards money, for credit is the expression of an advanced state of society, but as regards implements and instruments, machinery and transport, facilities of living and of communication, all of which required the use of metals. The need of them and the consequent market for them induced enterprising men to probe the hills and scour the deserts in search of the mineral deposits that are distributed with such perplexing irregularity in the outer crust of the earth. These deposits were not to be found near the smiling cornfield or the gentle hillslope, but in regions where geologic unrest had produced inequalities of contour and ruggedness of aspect, where the surface was bare of soil and the mountains exposed their heart of rock. The miner, therefore, left the sheltered valley and plunged into the outer wilderness. And in his wanderings, he found not only the metallic ore that was the immediate

object of his quest; he also discovered new tracts of agricultural land, and new dwelling places for his tribe. Returning home, he told the farmers and shepherds that fertile fields and lusher meadows were awaiting them across the range. They migrated thither, while he again adventured afar across the world, ever pioneering the advance.

This bare outline of a familiar story has already been punctuated by you with memories of the romance that has marked your own national expansion. The story of mineral exploration and racial migration is peculiarly the heritage of our people, the Anglo-Celts. It is the *motif* that runs through the drama of English and American history, more particularly during the last hundred years. Even in its barest outline it serves to suggest that the miner is the pioneer of industry and the herald of empire.

Early Discoveries

The first social organizations around the shores of the Mediterranean sent their prospectors to the hinterlands of Europe, Asia, and Africa. The gold of Ophir, the copper of Sinai, the silver of Laurium were part of the web and woof of those early civilizations. The mines of Iberia gave Hannibal the sinews of war against Rome, and the gold of Dacia strengthened the resources of Rome under Trajan. But the greatest adventure was that of the Phoenicians who passed through the Pillars of Hercules into the western ocean in order to reach the far Cassiterides, the tin islands that in turn were to produce those Cornishmen to whom this earth is one big mine. After Carthage and Rome, in turn, had been overthrown, the mining industries of the known world were disorganized. Desultory operations persisted in Hungary, Spain, and Saxony, but the Middle Ages to the miner were as dark below ground as above. Even the discovery of America, which marked the beginning of a new world movement, was not connected with a real advance in mineral exploitation, although associated with the gaining of gold and silver. It is true, the wave of Spanish conquest broke over the American continent, penetrating the treasure-vaults of Mexico and Peru. But the Spaniard devastated, he did not develop. He gathered the harvest that the patient Indian had sown by the laborious toil of centuries. Cortez and Pizarro were filibusters, not explorers; they were pirates, not miners. The *conquistadores* were no pioneers of industry; behind them arose the smoke of ruin and the dust of destruction. Even the great sea-captains of Elizabeth were but the sequel to an epoch of spoliation. After them, and in their wake across the sea, came the men who from Cornwall and Devon, from Saxony and the Harz, brought the technique of mining to the new

world, applying it peacefully to the mineral development of Mexico, Peru, and Chile, all along the regions previously ravaged by European freebooters.

But the great era of mineral exploration came with the discovery of gold in Australia and California. It was the prelude to a worldwide migration, an enormous expansion of trade, a tremendous advance in the arts of life, and the spread of industry to the waste places of the earth.

The color of energy began to tint the blank spaces on the map. The western half of the North American continent, all of Australia, the southern half of Africa, the northern half of Asia, were invaded, penetrated, and explored by those in search of gold, or other metals, and as each successive mineral discovery was made by the miner he called upon his fellows to come and take a hand in the good work. He was the scout far ahead of an army of development. Trade follows the flag, it is true, but the flag follows the pick.

Let us recall the story of that odyssey, and see for ourselves what human progress owes to its adventurous forerunners.

Discovery of Gold in California

First we turn to the American argonauts, the men who sought the Golden Fleece in California. Even the dates in this story are fragrant with romance, for gold was discovered by James W. Marshall on January 24, 1848, and the treaty of Guadalupe Hidalgo, which ended the first Mexican war, was signed on February 2. In other words, California was ceded to the United States 9 days after the great discovery, which, at that time, was not known to either government, fortunately for both of them, and for many others. Marshall had built a saw-mill for John A. Sutter at Coloma on the south fork of the American river, only 35 miles north-east of Sacramento. When the mill was ready to start, Marshall saw that the tail-race, or ditch leading the water from the wheel, was not deep enough. He proceeded to deepen it by opening the floodgates to full capacity, so that the swift current would scour the bottom. The water was allowed to run all night. In the morning Marshall noted the effect, and while doing so he saw several yellow nuggets. He hammered one of them, and decided that it was metal; he bit it and found that it was soft; he boiled some of them in a kettle and proved them insoluble in water. Thereupon he went to Helvetia, or Sutter's Fort, to tell his *patron* that he had found gold. Sutter tested the metal with nitric acid, some of which he found among his apothecary stores; he read the article on gold in his copy of the *Encyclopedia Americana*; he weighed the nuggets and compared them with coins; whereupon he also pronounced it gold.

That marked the beginning of the Golden Age in the foothills of the Sierra Nevada. Others found gold in near-by streams; the news traveled to the Atlantic seaboard, and thence to Europe. An excited migration began across the plains, over the Panama isthmus, around Cape Horn. The young, energetic, and adven-

turous hurried to the Eldorado that promised to fulfil the dreams of Raleigh's day. In 1851 California yielded \$81,294,700 in gold. It was no idle imagining, but an astounding fact. Nor does the output of precious metal measure the full consequence of the event. Cities were born, new avenues of commerce were created, the valleys of the Sacramento and the San Joaquin became the granaries of prosperous communities, the unknown territory in the middle of the continent was traversed and explored, the Great West leapt into vigorous life and became an integral part of the American domain. Moreover, among those enriched by the mines were men of initiative and imagination; like Balboa they stood on a peak in Darien; they saw the Pacific and the Atlantic as surely as he did, and to more purpose; they built a transcontinental railroad and tied California to the Union with links of steel.

You may say that most of these adventurers were not miners. I demur. What is a miner? He is the man who does the work of a miner, and that is, to extract ore from the ground. Most of the young and lusty men that rushed to California had never seen a mine, but that does not matter? They went to do the work of mining, and with the washing of the first panful of gold-bearing gravel they won the badge of Agricola. They had the machinery most used in mining: human muscle; they had the science most approved in that ancient art: organized common sense; they achieved the fundamental purpose of mining: to exploit mineral profitably. They came, they worked, they conquered; and from their labors has arisen a great and glorious commonwealth.

The Victorian Goldfields

Among those that went to California was E. H. Hargraves, an Australian, who was led by the analogy of geologic conditions to suspect the occurrence of gold in his own country, New South Wales. Returning thither, he was able on April 3, 1851, to inform the Colonial Secretary that gold existed at Lewis Ponds and other localities. He furnished ample proof of his statement, and was suitably rewarded. Hargraves was a man of exceptional intelligence, and the discovery that he made was among the least fortuitous of those that have changed history. It led immediately to search for gold elsewhere in the Australian colonies, then consisting of a few small and scattered settlements along the southeastern coast. In August of the same year a discovery at Buninyong, near Ballarat, started the first big rush to the Victorian goldfields. Sailors left their ships at anchor in Port Philip bay; clerks jumped off their stools to rush to the diggings; every able-bodied man shouldered his blanket and trudged through the bush to engage in the treasure hunt. After all the local population had stampeded, the news reached Europe and incited another economic Hegira. The gold seekers came in ship-loads and they expected to find gold in pailfuls; indeed, many of them were simple enough to believe that gold in quartz meant gold in double pints. They had much to learn, and most of

them learned it without delay from the severest of all teachers, *Der Herr Oberbergrat Professor Experience*. In the year 1853 Victoria yielded \$54,882,000 in gold.

From the mining-camps eager explorers plunged into the bush, or eucalyptus forest, which, like a sea of perennial foliage, then covered the habitable portions of the Australian continent. Outside them they found the grassy uplands on which the Australian was to grow a later golden fleece, and beyond these pastoral tracts they invaded the never-never land in which the rivers lose their way. The alluvial mining for gold was the beginning of a new era, it led to the discoveries of tin in Tasmania, of golden ironstone at Mount Morgan, of silver-lead ore at Broken Hill; it started a widespread mineral industry on the island continent; with it came a rapid growth of population of a kind superior to that of the first settlements; agriculture waited on mining, the need for food-stuffs stimulated husbandry, towns arose as if by magic, hastily constructed camps became permanent communities, a new civilization swept the aborigines into the interior, razed the primeval forest, furrowed the soil, cleaved the quarry, built docks, warehouses, and dwellings. Australia was born again. Captain Cook sailed along the coast and placed Australia on a naval chart; Har- graves placed her on the map of the world.

Among the more remarkable explorations of a later day I may instance Western Australia. The interior of that State is an arid plateau; it is the oldest land surface in the globe, and represents the basal wreck of a larger continent. It had been crossed by several parties of explorers, in the hope of finding some oasis in the desert or some outlet of the rivers that fail to reach the sea. In 1887 a discovery of gold was made by Anstey at Yilgarn. This attracted a few prospectors, who scattered farther inland. In October 1892 Bayley and Ford found a rich outcrop 500 miles from the coast, at Coolgardie. The outcrop was 50 feet long, 6 feet wide, and 5 feet high, spangled with coarse gold. In the March following they sold their claim for £6,000, and a sixth interest. During the ensuing year the new owners extracted 25.872 ounces of gold from 48 tons of ore, which, therefore, averaged 539 oz. per ton. That started the 'boom'.

Then was seen a strange spectacle. The sandy plain was covered with a monotonous scrub, sparse enough to be traversed easily, yet tall enough to restrict the view and render it easy for the careless to lose their bearings. Many were 'bushed', and perished miserably. Emerging from tracts of stunted forest, the gold-seeker found stretches of sand and spear-grass or else shallow depressions with clay bottoms from which the mirage lured him to unslakable thirst. Water was scarce, and uncertain at the best; a new peril faced the miner; early in the development of this region he learned to dig a hole to salt water and distill the brine in a rough apparatus. But a lack of the prime necessity of life was a grim factor in the search for gold.

With the whisper of each new discovery, crowds of

reckless men plunged into the outer desolation. Eager horsemen jostled those on awkward camels, whose swinging gait carried them past the mob of diggers trudging wearily forward. The incident known as the Siberia rush is typical of those days. The name Siberia is a biting satire, for the temperature is that of Tophet. A man came into Coolgardie one night with a story that gold had been found at a spot 30 miles to the north. The rumor vibrated like wireless telegraphy through the tents and corrugated iron shanties. Quietly one arose and another followed. Scores started on horses or on camels; hundreds went on foot, carrying their 'billies' and blankets on their shoulders or trundling their packs in wheelbarrows. Some took the wrong direction, and of these many lost their way and died miserably in the bush. Four hundred reached the scene of discovery. The only water available was in a 'soak' or water-hole seven miles distant. It was soon drained dry by the thirsty diggers. News came to Coolgardie that a water famine was imminent. A government official promptly dispatched a dozen camels bearing water to the succour of the adventurers. In the meantime, most of them, aware of the danger impending, had started to reach the nearest 'condenser' or distillation plant. Many died on the way, and many more would have perished save for the water brought by the camel-train. Nevertheless, in a few days there was another stampede in another direction. Thus the goldfield was explored. *Sic Etruria crevit.*

South Africa

We go next to South Africa. The Phoenicians sailed round it; the Portuguese landed on its shores; the Dutch founded sundry little settlements; but it was the finding of diamonds and gold that proved the 'open sesame' to the portals of the Dark Continent. Dutch hunters had roved northward from the Cape to the Vaal and the Orange; later Boers had trekked beyond both of these rivers; but none among them had imagined that diamonds were mingled with the pretty garnet, jasper, and agate pebbles bordering the stream. In 1867, in the hamlet of Hopetown, a child found a shining stone and played with it. The mother gave it to a Dutch neighbor, and he in turn asked an Irishman to ascertain what it was. But no one thought it worth anything until a local official noted that it scratched glass. Thereupon it was sent to a mineralogist, who did not hesitate to label it a diamond. But it led to nothing. No others like it were found immediately in the same locality. In March 1869—two years later—a Griqua shepherd found a magnificent diamond near the Orange river; it weighed 83½ carats, and was sold by him for 500 sheep, 10 oxen, and a horse. Subsequently, it brought £25,000, and became known as 'the Star of South Africa.' Indeed, it was the dawn of a new era. With that discovery began a great rush to the banks of the Vaal. At first from the neighboring parts of South Africa and then from every quarter of the globe there thronged a motley mob of fortune-hunters. The majority were men of British descent.

but even the stolid Boers were attracted, every European nation was represented, and with them all shades of black and brown, from the undiluted negro to the mezzotint half-breed. To all of these the winding shallows of the Vaal were as the valley of Sindbad the Sailor.

Kimberley and De Beers

Meanwhile, bigger discoveries had been made on the farmlands of the Dutch squatters, for it had been proved that the distribution of the gems was not restricted to the alluvium of the river flats, but extended through the surface soil and calcareous cement into the yellow and blue ground constituting the matrix of the diamond. Of these mines, the Kimberley and De Beers were the most important, and on their development hinged events of historic significance.

Among those attracted to the diggings were two remarkable men: an Oxford student named Cecil John Rhodes and a young Hebrew from London called Barnett Isaacs, famous later as Barney Barnato. One became identified with the De Beers, and the other with the Kimberley mine. Both of them saw that consolidation was imperative if the diamond market was not to be glutted. They fought strenuously for control; and Rhodes, backed by Alfred Beit, won. On July 18, 1889, the deal was closed by a cheque for £5,338,650, which was the price of the Kimberley mine. Since then the De Beers Consolidated has distributed £30,000,000 in dividends, and redeemed debentures to the value of £4,822,705.

Kimberley became a distributing point for the adjacent mineral region. In 1884 the De Kaap goldfield was discovered, whereby the districts of Barberton and Pilgrim's Rest came into existence. In 1885 Laurenz Geldenhuis found gold in shale on the hills north of the farm Roodepoort. Later in the same year Arnold detected gold in conglomerate lying on the farm Langlaagte. Both of these finds were made on the Witwatersrand or White Waters range. In December, Harry Struben, who had learned something of mining at Kimberley and Pilgrim's Rest, erected a 5-stamp mill, and with that the exploitation of the Rand may be said to have commenced. On July 18, 1886, the goldfield was proclaimed. The sober veldt sprang into busy life, and the greatest gold-mining industry of the modern world came into being. In the next 25 years the Rand produced £309,872,000 worth of gold, the maximum annual output being in 1912, when it was £37,182,795 from 25,486,361 tons of ore.

Rhodes and his partners participated in that development, but the diamond discoveries had an even wider influence, for they provided capital and energy for the extension of industry into the very heart of Africa. This brings us to the story of Rhodesia.

It was the ambition of Rhodes, always backed generously by Beit, to paint the map red. He worked and schemed to found a new empire in the northern hinterland—a word of which Rhodes was particularly fond. At that time German and Portuguese colonial expansion

seemed likely to absorb the vast interior made known by the explorations of Livingstone and Stanley. This threatened the future of that South African Union which Rhodes had in mind. By obtaining a concession from Lobengula, chief of the Matabele, who dominated the weaker tribes, he got a foot-hold. With this, in 1888, he incorporated the British South Africa Company, under royal charter, and by the purchase of concessions obtained by other adventurers, he consolidated a great tract of grazing and mining territory under the British flag.

Two years after the Chartered Company was formed, a military expedition was sent by Rhodes to Mashonaland, the southern part of this new country, to cut a road through the bush for 430 miles, from Tuli to Salisbury, which was founded on September 12, 1890. The members of this expedition, having accomplished their task peaceably, disbanded and went to work as prospectors. They uncovered the mines of the Gatooma district. In this case the discovery was not made in the usual way by tracing the gold of the river-bed or the detrital quartz on the hillside to its source in a vein or lode. The prospectors were guided by ancient workings, made by a forgotten people, probably of Arabian origin. And though the first operations were not successful, owing to lack of transport and supplies, they laid the foundation of a prosperous business. The men who did this work were preëminently the pioneers of industry; they were actually enlisted as the Pioneer Corps; they were guided by a famous elephant hunter; they were commanded by a mining operator, now chairman of several London companies: the rank and file included a large number of men familiar with mining at Kimberley and Johannesburg. Literally, they prepared the way for others, and started the mineral exploration that opened the interior of South Africa to orderly development and civilized habitation from the Cape of Good Hope to the sources of the Nile.

West Africa

West Africa as a mining region is identified historically with the Gold Coast, a traditional source of wealth. Herodotus speaks of the Carthaginians as receiving gold from native tribes that traded with wild people on the west coast of Africa. During the medieval period Europe obtained most of its scanty imports of gold from this source. Successive traders made an effort to lay hands on the legendary treasure of the region. But they proved abortive. A malarial shore and a dense jungle blocked the passage of the white man. Nevertheless, during the earlier half of the 19th century the export of gold is estimated to have averaged £350,000, or \$1,750,000 per annum, all of it the gleanings of native workers. Not until 1880 did real mining begin, on the initiative of an intrepid Frenchman, Marie Joseph Bonnat. An orphan, first a shoeblack and subsequently a *chef* in a Paris hotel, he met there two ivory-hunters to whom he offered his services for one year without pay. He was engaged, and went with

them to West Africa. When they retired from business, two years later, they bequeathed their equipment to him. Thereupon he went into business on his own account. On one of his ivory-hunting journeys he was captured by the Ashantis and remained a prisoner in the king's kraal for three years, until released by Sir Garnet Wolseley, in 1874, on the occasion of the Coomassie campaign. While a captive he saw the king's treasures of gold and heard of the diggings on the Tarkwa range. When liberated, he obtained a concession from the king of Eastern Wassau, and returned to Paris, where, in 1877, a company called the Côte d'Or was organized by him to operate the mines now known as the Taquah and Abosso. Forthwith other traders obtained concessions and took them to London, where two or three companies were formed. But these early enterprises did not prosper. As was the case in Rhodesia at first, the lack of transport, the scarcity of supplies, and sickness among the pioneers crippled operations. Bonnat himself did not live to see the fruit of his labors; he died at Taquah in 1881. His was a gallant spirit worthy to rank among the best of the heroic forerunners of civilization.

As a sequel to gold mining in West Africa came the clearing of the bush, the training of the natives, the building of a railway, and the introduction of sanitary reforms. Then followed the finding of tin on the highlands east of the Niger, where now a thriving industry is established. This, in turn, has admitted light and air into the tropical jungle, facilitated the establishment of cocoa, rubber, and cotton culture, and brought a dark corner of the earth within touch of the vitalizing forces of industrial progress.

The Story of the Yukon

And now, for our last illustration, we go to Canada. The story of the Yukon is so recent as only to need recalling. That remote corner of the North American continent was slow to be unveiled. The mountains guarding the coast discouraged the Russians who crossed the sea from Kamchatka; the main range barred the way of the English fur-traders and French *voyageurs* who came overland. In 1843 the Russian Zagoskin ascended the Yukon as far as the Tanana, and about the same time Robert Campbell, an agent of the Hudson's Bay Company, descended the river to its confluence with the Porcupine. But the only object of these intrusions into the inhospitable wilderness was the trade in furs. No whisper of gold was heard.

The first gold to come from the Yukon consisted of two nuggets obtained from an Indian in 1880. Small parties of prospectors began to test the creek-bottoms. Encouraging discoveries were made, but none of them was remarkable; moreover, the precarious food supply and the shortness of the season checked enthusiasm. In 1896 the annual output of gold was about \$1,000,000, of which only \$300,000 came from Canadian territory, for the more productive diggings were on the Alaskan, or American, side of the boundary, which is about 50 miles below Dawson, where the waters of the Klondike

mingled with those of the Yukon. Up to that time this vast watershed was of no particular consequence as a mining region. Then suddenly, out of a clear sky, came the tremendous shout of a great gold discovery.

The First Gold

On July 14, 1897, the steamship *Excelsior* arrived at San Francisco bringing miners laden with sacks of gold. They told stories of a new Eldorado in the North, in the valley of the Klondike, on the edge of the Arctic. Again the world heard the bugle-call of adventure. The response was instant. During the following winter 33,000 people landed at Skagway on their way to the Klondike. An eager procession climbed the passes that led over the coast range to the headwaters of the Yukon, down which they voyaged in boats and rafts to Dawson. The horrors of that scramble are almost forgotten. Men, and women also, devoid of experience, physically unfit, laden with packs, toiled up the long ascent in a frenzy to lay hands on the gold. Before this mob reached the diggings the richest ground had been located by the miners and traders previously in the country. Yet some of the newcomers also fared well. The romance of the rush was not with the luckless wastrels, the greedy courtizans, or the drunken desperadoes, but with the quiet strong men who greatly endured and nobly overcame the trials of an unaccustomed life, and returned home to become leaders in a peaceful community.

In 1898, the Klondike yielded \$10,000,000, and in 1901, \$22,000,000. The total output so far has been \$150,000,000.

The story of the discovery remains to be told. In the summer of 1896 Robert Henderson, a Nova Scotian, who had mined in Colorado, found gold across the divide from the Klondike. At this time George Carmack, a squaw man, being short of fresh meat, went up the valley of the Klondike in search of moose. Two Indians went with him. Turning up one of the tributary creeks, they worked their passage through the thick underbush and the thicker mosquitoes until fatigue necessitated a halt. While resting, the two Indians panned the gravel and found gold. Crossing the divide, Carmack and his Indian friends visited Henderson's camp, but they said nothing to him about their discovery, for he showed a dislike of Indians. Returning, they found more gold on the same creek, now famous as Bonanza. Thereupon, Carmack and each of the Indians located a claim. That was on August 17, 1896. Putting the gold they had panned into a cartridge-shell, they hastened down the Yukon to Forty-mile, which was the nearest recording office.

This event opened a new province to human industry. Within a couple of years big steamers were ploughing the waters of the Yukon, a railway had been constructed over the coast range, the telegraph had linked the northern frontier with the nerve centres of the world, and new communities had arisen in the very heart of a vast solitude. It was not long before agriculture was started close to the Arctic circle and chil-

dren played where lately moose and caribou had roamed at will. Once more, the miner had started the springs of life and called a new world into being.

The Lure of Gold

Other examples of pioneer work might be instanced, did time permit. You will have noted that the lure of gold was the incentive to most of these explorations. The reason is obvious. Gold is a metal occurring in nature in a nearly pure state; in its alluvial form it is readily separable from the river gravel; and even from its matrix in the rock it is extracted by easy methods. Moreover, it commands a high price, and a free market, so that it can be transported in small bulk and sold in unlimited quantity. Gold mining, therefore, has been the prelude to the exploitation of the base metals existing in complex ores. The simple operations of the gold miner have preceded the establishment of economic conditions favorable to the more complicated business of winning the other metals.

The British empire and the American commonwealth alike have advanced in the track of the miner. He made the Great West a part of your heritage; he conquered the Overseas Dominions more truly than the soldiers of the King. The curtains that hid Central Africa were parted momentarily by the slave-trader, the elephant hunter, and the missionary, but when these emerged those curtains closed again. It was left to the miner to place his candle so that like "a good deed in a naughty world" it might illumine a path for human industry. The primeval forests, the sunlit valleys, and the grassy plains of Australia remained as they were in the morning of time until the prospector called for his own people to come thither across the sea. The fur-trader traversed the snow-clad plains and penetrated the pine-clad mountains of the Canadian Northwest; the salmon-fisher sailed into the long estuaries; but neither of them touched the heart of that great lone land. Not until the pick of the miner awoke echoes that had slumbered since creation did the vast solitude respond to the pulsations of human endeavor. Hunters, traders, even soldiers and farmers, crossed the prairies from the Mississippi to the Rocky Mountains, and adventured over the desert to the Pacific Coast. They carried the flag, and they hoisted it over the new domain, but it was an empty conquest and a vain annexation until the miner spoke the word that set the world aflame.

The Track of the Prospectors

After the prospector has come the mining engineer. The scout has gone in advance of the captain of industry. Those of you that have crossed the range in winter know how the leader breaks the trail by leaving foot-prints into which his followers tread, step by step, greatly to the safety and ease of their travel. That is what the mineral explorer has done for the mining engineer. That is what the mining engineer has done for those behind him. Some of you have been prospectors as well as engineers.

"Have you known the Great White silence, not a snow-gemmed twig a-quiver?"

"Have you broken trail on snowshoes; mushed your huskies up the river?"

"Have you marked the map's void spaces,
"Felt the savage strength of brute in every thew?"

Again, I ask you to recall how you threaded the pathless forest on your way to examine a new mineral discovery. On the trees at intervals you have seen that the bark was chipped. The trail has been 'blazed' by the prospector, making it easy for you and others to follow. That is what the miner has done in a larger way for civilization. He has done it with geographical exuberance and equatorial amplitude. From "the stark and sullen solitudes that sentinel the Pole" to the "steaming stillness of the orchid-scented glade" in the Tropics, he has left his mark. You know that. No need for the prospector to complain to you, like Kipling's explorer:

"Well I know who'll take the credit; all the clever chaps that followed—

"Came a dozen men together—never knew my desert fears;

"Tracked me by the camps I'd quitted, used the water holes
I'd hollowed.

"They'll go back and do the talking. They'll be called the
Pioneers!"

No; not by the men of the Columbia School of Mines, who have shared the prospectors' camp-fire, his blankets, his flapjacks, his bacon and beans. You will give credit to whom it belongs. To the man with the faith of a child and the heart of a viking, to the man who has tramped and toiled until he heard "the mile-wide mutterings of unimagined rivers and beyond the nameless timber saw illimitable plains"; to the miner who has crossed the last range of all and lies in the only prospect-hole he could not dig; to the man who was the herald of empire and the pioneer of industry; to him who blazed the trail.

Revival of the Platinum Industry in the Urals

After predicting the obvious exhaustion of the platinum placers of the Urals for years, a note from that region states that in the near future the Nikolaie-Pavodinsk district will be an important centre for the production of platinum in the Urals. With its transfer into the hands of a responsible company investigations are being conducted under the guidance of Professor Dyupark and a comprehensive survey is being made. The platinum deposits within the limits of the district referred to have long been known and exploited to a limited extent. But the new owners have decided in view of the splendid results of the investigation, to operate on a much larger scale. On the river Nyasma and others, dredges are being built, one of these is of the American type (Marion) and is driven by electricity. It would appear from reports that the reserves of platinum in the Urals are not so limited as many believe.

The Buckhorn Mines Company's Power Plant

By E. H. LESLIE

While the use of the locomobile type prime mover is by no means an innovation in steam power-plant engineering, having for many years been in successful operation in European countries, and Germany in particular, its advent in this country is marked with the initial installation at Beowawe, Nevada. Here two 350-hp. units are in successful operation supplying power for the Buckhorn mines and mill, the electric power generated at Beowawe being transmitted a distance of 35 miles to Buckhorn.

This type of engine, as will be seen from the illustrations, bears more semblance to a modern traction engine, which has been inverted and remodeled for stationary power purposes, than any of the standard types of American steam-engines. The surname of this type of engine, 'locomobile,' suggests its progenitor, and in fact it is an adoption of locomotive type power-plants to stationary requirements. The two Buckhorn units have a capacity of 350 hp. each. The engines are compound, the high-pressure cylinder being 11 $\frac{3}{4}$ in. diameter, and the low 23 in., with a 20-in. stroke, and are operated condensing.

The boiler plant upon which the engine is superimposed presents many interesting features. The boiler tubes are mounted as shown in Fig. 1, and are easily removed from the shell of the boiler and another inserted if occasion demands. The illustration shows a set of tubes which have been removed, and furnishes an idea as to the boiler construction. In the operation of the plant, the engine has been 'shut-down,' the boiler replaced, and the engine again under steam in ten hours. While this record is itself a good one, a

still better record will be possible under present operating conditions, which provide for having a spare boiler readily accessible. Since the beginning of operations it has been necessary to replace one boiler. This is attributed to the fact that the boiler was used for sinking a well before the power-plant was put into commission, and in so doing it was necessary to use a boiler water which was extremely alkaline and also contained considerable oil from the pumps. Since the removal of this boiler, no further troubles have been experienced. It is hoped that a permanent supply of pure artesian water for boiler purposes will soon be obtained.

The Fire Box

The fire-box end of a unit is shown in Fig. 2. At this plant California crude oil is used for fuel, and is fed in by two injectors. The fuel oil is delivered at the plant in standard tank cars and discharged into a steel sump tank of 8000 gal. capacity, and from which it is pumped by means of a duplex 6 by 4 by 6 Platt Iron Works oil-pump to the storage tank. The storage tank is of corrugated iron and has a capacity of 50,400 gal. (5 carloads). The oil is heavy California petroleum of 16°B. In cold weather it is often necessary to heat the oil before it can be pumped. From the storage tank the oil flows by gravity to a small feed tank on the inside of the building from which it flows to the burners. There are two nozzle-injector burners for each unit. Oil and steam are admitted through the nozzle. The steam, being under a high pressure, atomizes the oil and acts as an inject-

tor in drawing the oil from the fuel tank, heating, atomizing, and injecting it into the furnace. With the exception of the pump for raising the oil from the sump to the storage tank, the handling of the fuel oil is by gravity. Under present working conditions, the two units require about 1550 gal. of fuel oil per day, or about 1 lb. of oil per brake horse-power hour. While the engines have a capacity of 350 hp. each, under present working conditions the load is about 550 b-hp., or 275 b-hp. on each unit. With an increased load there would undoubtedly be a better fuel economy and increased thermal efficiency. The present fuel oil consumption, however, is by no means excessive, and compares most favorably with the oil-fired boiler and steam-engine combination in general use.

Engine Pumps

The boiler feed water pump and condenser pump are in tandem and on the same drive at the side of the boiler, and are driven by a belt which is connected with the main engine and generator shaft. The pumping device is most efficient, and the vacuum is kept at about 75 cm. An injector is held in reserve for boiler feed and is shown on the left of the boiler in Fig. 2. The boiler feed water heater is also shown in the same illustration. The exhaust steam from the low-pressure cylinder is drawn by the vacuum pump through the feed water heater, in which are the feed water coils from the feed water pump and

connecting with the boiler.

The steam as generated passes to the steam dome and from thence to the super-heater, which is seen in Fig. 3 as the extension of the boiler proper. The steam from the dome enters at the rear of the super-heater and passes through a system of coils, which are given a super-heat by excess furnace gases. The steam then is conducted through an insulated pipe, shown in Fig. 3 from the super-heater to the engine proper.

The smoke and burned gases pass from the super-heaters through a brick-lined conduit under the engine-room floor to the stack, which is of steel and 160 ft. high. A damper for regulating the draft is placed in the brick conduit and turned by a key in the floor of the engine-room.

The steam as delivered at the high-pressure cylinder has a temperature of 720°F. In the design of this type of power-plant, every effort is made to maintain high temperatures, and toward this end super-heat, compactness of design, and thorough insulation have tended toward higher thermal efficiencies than those shown in the average boiler and steam-engine combinations. While as yet no indicator cards have been taken, and it is impossible to know either the mechanical or thermal efficiency of the plant, the load and fuel consumption are evidence of a satisfactory performance in this respect.

For synchronizing the two units of the plant a retarding device is placed on each unit, by which the

FIG. 1. BOILER TUBES.

FIG. 2. FIRE-BOX END OF ENGINE.

FIG. 3. SUPER-HEATER AND SYNCHRONIZING MECHANISM.

FIG. 4. GENERATOR.

speed of the engine and generator, which is direct connected, may be retarded in connecting in the other unit after a 'shut-down' of one of them. This retarding device is shown in Fig. 3, being an attachment on the governor, which is within the fly-wheel as shown. The retarder is operated by a hand wheel, shown in the illustration, which acts upon the governor and in

flexible coupling with the generator. The coupling consists of two annular castings, one within the other, which allows an inch of play between them. These two rings are laced together by two strips of leather belting. In this manner, all of the vibration in the engine is taken up in the coupling and none is transmitted to the generator.

FIG. 5. SWITCH-BOARD.

turn upon the valve-rod and piston valves of the cylinders, which type of valve is used in this engine. The valve-rod has a pointer attachment which slides with the rod over a graduated scale, which has been calibrated to indicate, by measuring the travel of the pointer, the approximate horse-power which is being developed in the cylinder.

Metallic packing is used throughout the engine, and bearings are of the finest bearing alloys. The bearings are fitted with oil cups, and only the best grades of lubricating oil can be used. A careful watch must be kept on the bearings, as they are always at a temperature which will scarcely permit being touched with the hand, and a very temporary suspension in lubrication results in the burning out of a bearing, with its attendant 'shut-down' and delays. Since beginning operations there have been two bearings burned out at this plant, but with a familiarity with the engine and careful supervision, little difficulty is to be expected from this quarter. Five barrels of lubricating oil is used per month on the bearings, guides, etc.; and three barrels of cylinder oil is used per month in the cylinders of the two units. The cylinders are lubricated by means of an oil pump which is driven from the piston rod.

Over-All Dimensions

The over-all dimensions of this particular locomobile boiler and engine unit are 24 by 14 ft. 6 in. base and 10 ft. high. The engine goes under the house name of Type V.K.13, and was made by the R. Wolf Maschinenfabrik at Magdeburg, Buckau, Germany.

The engine is direct connected through a Zedel Voith

The generator is mounted on a large concrete block as shown in Fig. 4. The two generators were made by the General Electric Co., and are of the type A.T.B., form S, manufactured by this Company. The generators are 3-phase, 275-kw. machines, operating at 480 volts, 415 amp., and 225 r.p.m. The power factor is 0.8. The generators are excited by General Electric continuous current generator of form A, rated at 35 kw., 280 amp., 125 volts, and 850 r.p.m. The exciters are driven by a belt and pulley connection with the main generator shaft. A separate motor is about to be installed for driving the exciter. This motor is of the General Electric manufacture rated at 35 hp., 60 cycles, 46 amp., 440 volts, and 680 r.p.m.

The electrical equipment also includes four transformers, three being in use, with one extra. These transformers are General Electric apparatus, rated as Type A, Form B, 60 cycles, 219 kva. The current is thus stepped up from 480 to 33,000 volts for transmission to the Buckhorn mines and mill, 35 miles distant. The switchboard, shown in Fig. 5, is of gray marble fitted with a curve drawing watt-meter, watt-hour meter, curve drawing volt-meter, voltage regulator, together with volt and ampere meters, switches, and other equipment. There has also been installed an aluminum lightning arrester for the protection of the plant. The engine-room is also fitted with an overhead hand-operated traveling crane, for facilitating the movement of large spares and parts. The centrifugal pumps for the circulation of water through the cooling towers, seen on either side of the power-plant building, were made by the Krogh Manufacturing Co. These pumps are direct connected with small 3-hp. General Electric motors.

As a small and compact power-plant, the locomobile type at this property presents many attractive features; the fuel consumption is low, as are the attendance charges, only two men, an engineer and fireman, being required per shift of 8 hours. While exact figures are not available at this time, it may be said that efficiency of the plant compares most favorably with the regulation boiler and steam-engine combination. The super-heating and high temperatures which result from the arrangement of engine and boiler have been the cause of some mechanical difficulties, of which, however, up to the present, nothing of a serious nature has developed.

Reduction of Radium Ores

By GEORGE D. VAN ARSDALE

The work on the extraction of radium started several years ago, due to the personal and philanthropic interest Dr. Douglas felt in the subject. At that time little general information was available. The object of the experiments was to devise, if possible, a method of making radium at a lower cost than the market price at that time. Naturally, since the amount of high-grade carnotite was limited, the first experiments were on concentrating low-grade material. I was uncertain at the start whether, in a mechanical concentrating scheme, the radium would follow the mineral or not. The tests showed, however, that a concentration of the radium as well as of the other mineral constituents took place.

The method adopted was the obvious one that has been used by others, namely, to crush the ore sufficiently to free the carnotite from the sandstone grains and then to separate the resulting slime by agitation and decantation from the sand. The ore first treated was from Colorado, and contained about 1.25% UO₂; our tests showed a concentration of about 5 into 1, with an extraction of about 80% of the radium. The early tests were made by photographic methods alone, so that the above percentage is only approximate, but I believe is nearly correct.

Use of an Acid Solvent

Extraction experiments were then started. There were a number of possible methods of treating the ore, but extraction with an acid solvent seemed simplest. Since radium is very similar to barium, any chemical method suited to the extraction of barium would be expected to remove radium also. Fairly good results were obtained in small laboratory tests by the use of hydrochloric acid as a solvent. In all the ores tested there were appreciable amounts of barium, although the amount was quite variable. I found that the barium was soluble in the acid used, and that the washed tailings apparently carried little radium. Tests on a scale of about 100 lb. per day were then arranged for, and the results from this work being encouraging, plans were then made and apparatus secured for a larger plant.

Tests up to this point had given extractions of 80 to 90% of the radium content of the ore, checked by samples tested by Professor Boltwood of Yale, so that it was safe to go ahead. The large-scale work was disappointing, however, since the final amount of radium secured was only about 30% of the estimated content of the ore. This larger work was not done under my personal supervision, and there were some unexplained losses of radium, so that I feel that, properly conducted, this method is capable of yielding, say,

80% of the radium content of an ordinary carnotite. Further tests will be made and the question definitely settled.

The work was much complicated by the necessity of making a special grade of uranium and vanadium product, and I am inclined to think that, except under special conditions and when there is a ready market for these products at a good price, it will pay better to treat the ores simply for their radium content.

Cost of Radium

From a carload of ore there was obtained between 50 and 60 mg. of radium, which was barely 30% of the amount present; deducting the cost of plant equipment, which should not be charged as a production cost, and also deducting the cost of experimenting on the uranium product, which, of course, would not be repeated in future work, the actual cost of the radium made, including everything else and crediting the returns from the sale of uranium and vanadium, was \$78 per milligram of pure radium bromide. Naturally, if the extractions had been as high as expected—about 80%—the cost would have been correspondingly lower. I believe that radium can be made by this method in the East, from 1 to 1½% carnotite ores, under proper conditions, at a cost not to exceed \$30 per milligram of pure bromide, and probably somewhat less. This, of course, assumes approximately the present price of carnotite ore. I have since confirmed my earlier tests, and it is possible that something may still be done with the method, although the large-scale test was not a commercial success, due to the unexplained losses.

One must, of course, recognize that where sulphates are present in an ore, or in the water or acid used, the solubility of the radium is diminished, but in any case the radium will be either in solution or left with the sands as insoluble sulphate. If the latter, the separation of any considerable amount is a comparatively simple matter. Credit should be given to A. H. Phillips as one of the earliest investigators of carnotite in this country, whose methods, substantially, I adopted.

Quite recently I have found an interesting new method of precipitating uranium and vanadium, and while much remains to be done to prove its value, I believe that results will come from its use. The extraction of radium itself is comparatively a simple matter, and most of the complication in the treatment of carnotite ores comes from the great difficulty in separating and preparing uranium and vanadium in forms sufficiently pure to be readily salable. It seems probable to me that the eventual method by which radium will certainly some day be produced at a cost that will make its use generally possible, will have to be a much simpler method than any heretofore described.

The Chilean Nitrate Industry—II

By LESTER W. STRAUSS

The present system of treatment, as in vogue since 1876, was introduced by J. T. Humberstone, resident manager for the Agua Santa Nitrate & Railway Co. He adopted the Shank process which had been previously used only in the soda industry. Mr. Humberstone, known in the province of Tarapaca as the 'Father of the nitrate industry', ingeniously modified the Shank system to suit local purposes. In the early days of the industry the boiling tanks were placed over an open fire; in 1856 heating was done by blowing steam into the liquor covering the caliche. This innovation gave higher recoveries at less costs.

The leaching of caliche is based on the fact that so-

CALETA ALTA, A NITRATE PORT.

dium nitrate is decidedly more soluble in hot than in cold water, also that, in cooling, the hot saturated solutions (which have been produced in the presence of a large excess of common salt) first precipitate sodium chloride, and (on the further reduction of temperature) the salt is re-dissolved, yielding almost pure nitrate of soda. Sulphates, which occur in less percentage, react similarly but because the amount present is less, they do not seriously contaminate the soda. The application of the principle is described in detail below but it is worthy of note at this point that the refined nitrate is crystallized out of hot solutions by cooling, and the cold mother liquor (saturated) is sent back to be mixed with material ready for leaching in the boiling tanks, thus running no nitrate solution to waste. Early in the process considerable salt, from the caliche, goes into solution but later is re-precipitated, as the temperature rises and continues, in the presence of an excess of undissolved nitrate in the caliche. A portion of this nitrate is dissolved, the salt remaining with the earthy matter sometimes occurring as white crystalline masses or replacing the nitrate in the caliche and forming a crustation over same. The hot solutions leave the tanks—at a temperature between 80° and 90°C.—and pass through to settling tanks where mud separates out, as also considerable salt due to the drop in temperature to between 60° and 65°C. (the settling takes about

two hours). The solution of saturated nitrate then passing to the crystallizing tanks, locally called *bateas*.

Solution of Nitrate

The following table, by M. A. Prieto, shows approximately the solution of nitrate and chloride of sodium from an excess of both salts, in 100 c.c. of water, at varying temperatures:

| Temp., ° C. | Nitrate, grams. | Salt, grams. | Density, ° Twaddell. |
|-------------|-----------------|--------------|----------------------|
| 10 | 49.50 | 27.0 | 72.0 |
| 20 | 57.00 | 26.0 | 75.5 |
| 30 | 65.80 | 24.0 | 78.5 |
| 40 | 75.50 | 22.5 | 82.5 |
| 50 | 86.50 | 20.5 | 87.0 |
| 60 | 98.00 | 18.9 | 91.5 |
| 60 to 65 | | | 90 to 95* |
| 70 | 110.40 | 17.5 | 96.0 |
| 80 | 123.80 | 17.0 | 100.5 |
| 90 | 139.00 | 16.2 | 103.5 |
| 100 | 157.50 | 16.0 | 107.5 |
| 110 | 184.00 | 15.4 | 108.5 |
| 120 | 220.00 | 15.0 | 110.5 |

*Temperature and density corresponding to the hot solution stated below.

The number of degrees Twaddell multiplied by 5 plus 1000 equals the specific gravity, water being 1000.

Every charge of caliche is given four boilings, with solutions each successively weaker than the previous one admitted, and one fresh-water wash. Thus each mother liquor goes through four boilings with material successively higher in nitrate, finally reaching the desired density varying from 90° to 95° Twaddell; the density desired depends on the quality of the caliche leached and the quality of the salitre or nitrate, 95% (minimum) NaNO_3 , to be made. High density means cleaner nitrate but with increasing costs due to the raising of more steam; the economical limit of the density raising determines this point. The calculation of the water to be used in leaching is an important economic consideration: too much water means that an excess of fuel must be consumed—too little water leaves part of the caliche undissolved. The average specific gravity of the hot saturated liquor, or *caldo*, for the settling tank, is 1.50, while the mother liquor, leaving the crystallizing tank, is 1.41 (82° Twaddell).

For a clear conception of the process it will be assumed that tank No. 5 has been charged with caliche and steam has been turned on. Mother liquor, already through three boilings, is admitted at the top and boiling proceeds until the density limit, the economical point, is reached. The contents of the tank are allowed to settle a few minutes, after the steam has been shut off: the solution (*caldo* or saturated liquor) is then drawn off from below the false bottom and goes to the settling tanks. The perforated false bottom serves not only as a space for settling out the fine mud

or slime but as an equalizer for the circulation of solution through the caliche. The fine mud is sometimes treated separately for its nitrate contents. Tank No. 6, in which second stage liquor is boiling with twice boiled caliche, is then ready to have its siphon—to tank No. 5—opened, the liquor discharging over the top of No. 5. Meanwhile, the other two siphons of the series are opened up and a solution of weaker density enters the top of the tank while the higher one leaves through the bottom. Tank No. 8 is being filled with mother liquor pumped back from the crystallizing tanks, and warm wash water, as quickly as the solution is leaving for tank No. 7. When the liquor in No. 5 reaches the minimum economic density, due to solution from No. 6, the circulation of solutions is stopped and boiling again started. Due to the four different densities the solutions will not be at the same level in the four tanks, so that pumping is frequently necessary to help the siphons. When boiling has continued for some time, the liquor in tank No. 5, now thrice boiled, is passed to tank No. 1, the caliche in this being ready for its first boil. Tank No. 8 has now been washed with cold water to cool down the leached caliche and to remove whatever nitrate remains in the mass, which is shoveled out through the two discharge gates; this residue (*ripia*) still carries between 7 and 10% NaNO_3 . At a later day this low-grade residue, or tailing, may be re-treated when the high-grade caliche and costra have been mined and the export tax reduced. The cold wash water is collected in a sump to be used, at the next transfer of solutions, in tank No. 7.

Time Required for Leaching

The total time taken for a charged tank, from the first operations until the final discard of the residue, is usually 27 hours. The saturated liquor goes to settling tanks, as already mentioned. The sediment, in these tanks, is said to carry up to 40% NaNO_3 ; this is sometimes washed, but more frequently discarded. The crystallizing tanks of sheet iron are 18 ft. square, with an inclined bottom so that the depth is 27 in. at one end and 33 in. on the opposite. A tank holds about 600 cu. ft. of solution or approximately 30 tons. A tank is never filled to the brim. From five to ten days are allowed for the cooling and crystallizing of the nitrate which forms in friable crystalline cakes—

about 8 in. thick—on the bottom and sides of the tank. At the expiration of this time the mother liquor is drawn off and pumped back to a boiling tank in which

VIEWS OF A NITRATE REFINERY.

the material has had its third boil. The crystallized nitrate is shoveled into cars, and run on a trestle to be dumped on the drying floor, later when dry—to be shoveled into 100-kg. sacks (220.46 lb.). The nitrate, now refined, is referred to as salitre in the trade and contains between 95 and 96% NaNO_3 . The remaining percentage (4 to 5%) consists of chlorides, sulphates,

and moisture. Nitrate under 95% NaNO_3 content is penalized according to the amount below this figure. While apparently a simple process the average recovery of nitrate from caliche is only slightly above 60% and from costra the recovery is lower. There are no losses due to evaporation, and only a small amount in handling solutions, but the heaviest losses are those resulting from the unleached caliche, that has been crusted over by salt, and to a lesser degree the nitrate in the sediment below the crinolin and in the settling tanks.

The following analyses give an idea of the constituents of the various solutions, also salitre:

| | Solution to settling tanks. | | Solution to crystallizing tanks. | | Sol'n 'mother liquor' to boiling tanks. | | Salitre, %. | |
|--|-----------------------------|------|----------------------------------|-----|---|------|-------------|-------|
| | Degrees Twaddell: | | | | | | | |
| | 90 | 100 | 92 | 102 | 82 | 86 | | |
| | | | grams per litre | | | | | |
| Total nitrates as nitrate of soda..... | 680 | 900 | 700 | 920 | 460 | 537 | 94.9 | 96.2 |
| " chlorides " | 260 | 150 | 190 | 140 | 160 | 150 | 2.0 | 0.9 |
| Perchlorate of potash | 15 | 2 | ... | ... | 15 | 2 | ... | ... |
| Iodate of soda | 6 | 4 | ... | ... | 6 | 4 | ... | ... |
| Total sulphates | 70 | 52 | ... | ... | 70 | 52 | 0.6 | 0.4 |
| Insolubles | ... | ... | ... | ... | ... | ... | 0.2 | 0.1 |
| Moisture | 419 | 392 | ... | ... | 699 | 685 | 2.3 | 2.5 |
| Total | 1450 | 1500 | ... | ... | 1410 | 1430 | 100.0 | 100.0 |

In the Agua Santa plant, from which source the above analyses have been obtained, there are 32 boiling tanks, 6 settling tanks, and 192 crystallizing tanks. 900 tons (metric) of caliche can be treated in 20 tanks per day, yielding an average production of 1300 quintals of salitre per day (40,000 quintals per month).

Method of Analysis

The method of analyzing caliche is rapid after experience in the work has been had. Five grams of finely pulverized sample is boiled in 100 c.c. of water, filtered, and the filtrate made up to 100 c.c. Of this 20 c.c. is taken, to which 10 c.c. of sulphuric acid (50° Baumé) is added, and the solution heated in a porcelain evaporating dish to between 70° and 80°C., this temperature is maintained, the solution being stirred with a thermometer, and titration made with a 12% ferrous sulphate solution, acidulated with sulphuric acid. A dark brown coloration is produced which disappears on stirring but leaves a sage green tint to the solution, that deepens as titration proceeds. Effervescence is noticed as the titration approaches completion; the end point is reached when further addition of ferrous sulphate ceases to produce the brown coloration. Practice is necessary to note the end point; the method is correct to within 2%, which is near enough for practical purposes. In a few of the modern plants the method is checked periodically with more exact determinations. In the finished product for export, the nitrate content is estimated by difference; export salitre must contain 95% NaNO_3 and the so-called refined, which is really only selected, 96% NaNO_3 and less than 1% NaCl (and a minimum perchlorate of potash). The 'nitrate by difference' method has been found to yield high results (almost 3%) in NaNO_3 . The 'Devarda' method, with modifications, gives more satisfactory results; this involves the direct analysis for NaNO_3 .

Operations in Agua Santa begin at 4 a. m. and continue to 4 p. m. No work is done at night, but the treatment plant operates on Sundays. The steam plant consists of nine boilers—Lancashire type—of which 5 or 6 are in use all the time, for heating the solutions, the caliche, and making distilled water for local consumption and the locomotives. No drinking water is close at hand as that used for the solutions is too saline.

The source of this water is from the pampas near an old river course, which at intervals of seven to eight years becomes a roaring torrent due to cloud bursts near its head. Ordinarily the course is dry, so that wells, 40 to 80 ft. deep, must be sunk to reach the underground water. The pipe-line to the treatment plant or *maquina* may be over 6 miles long; electric pumps are used. The feed water to the boilers is pre-heated by the waste steam from the coils; condensed water, from the heating coils, after leaving the boiling tanks passes through a steam trap. At some plants water is piped (occasionally, as in Antofagasta, over 100 miles) from sources in the Andes.

Output of Individual Plants

The output of individual plants varies from 200 to 8000 tons of salitre per month. The largest oficina or plant is the Alianza in Tarapaca, which produced over 1,680,000 quintals in 1912, with a greater output still possible. There were 9 plants which yielded over 1,000,000 quintals each, in 1911, as compared with 11 in 1912. The smallest output recorded was 11,000 quintals (1912). Prior to March 1909, there was a restriction of output regulated by the Nitrate Combination; restriction has been again effected by the producers.

With the larger producing companies steel structures, as well as modern mechanical appliances, prevail; a side view of a treatment plant resembles a multiplane flying machine. The buildings are not housed-in, only terraced roofing of split bamboo cane being used as a protection against the glare and heat of the sun. The average cost of a nitrate treatment plant, exclusive of the cost of the ground and associated expenditures pertinent to operations, also the promotion expenses,

etc., is approximately £1 (\$4.80) per quintal of salitre capacity per month; including necessary accessory equipment such as light, tools, railway cars, carts, mules, etc., the cost is about £1 10s. (\$7.20). The total capital invested in the industry, inclusive of equipment (also eight railways) might be £30,000,000 or \$144,000,000.

The fuel used in the industry is principally coal, brought from England or Australia in ships or steamers, which return with nitrate; within recent years the use of petroleum has met with much favor. The California crude oil and residuum, the specific gravity varying from 14° to 16° Baumé (0.960 to 0.972 specific gravity), is brought in large tank steamers to Pisagua, Junin, Iquique, Tocopilla, Antofagasta, and Taltal and pumped, through submerged piping, to huge tanks on shore; it is then distributed, in tank cars, to the various plants. The cost placed at the boilers is about \$15 per ton of 2240 lb. Coal would cost from \$12 to \$14 at the same point, per ton. The Peruvian crude oil, specific gravity 0.860, or deprived of its benzine specific gravity 0.881, is landed, at all the above mentioned ports in small quantities for use in Diesel engines which are coming into general use for generating power. The Agua Santa Co., which was the first to use petroleum (in 1903), importing through the port of Caleta Buena Peruvian oil for its own use, and that of the plants served by the railroad (Agua Santa). This Company now employs it for all purposes as fuel for its several plants. The present cost is slightly higher than the California residuum. At Caleta Buena the oil is pumped to the shore tanks through a floating hose, and again pumped to the railroad station on top of the cliff, 2440 ft. vertically, through 7000 ft. of steel piping; a double line, each being 3 in. diameter. Powerful electric pumps, made in the United States, work very smoothly against the 1200-lb. pressure. In all 60,000 tons of oil is handled at Caleta Buena per year and the consumption is increasing.

Power Plant at Agua Santa

The power plant at Agua Santa, which (inclusive of the boiler consumption) consumes about 450 tons of oil per month, consists of three sets (one in reserve) of three-cylinder Diesel engines, each of 120 hp. Each engine is belt-connected with a 100-kw. Westinghouse dynamo, which furnishes the necessary power for the treatment plant, or máquina, and electric lights about the entire plant. The crushers, there are six of the Blake type, have 24 by 17-in. openings and are driven by two 40-hp. motors; the six pairs of rolls, 36 in. diameter, are driven by two 20-hp. motors. Electric winches are used to haul the caliche to the boiling tank and the leached material, or ripio to the waste dump. Electric power costs 1d. (2c.) per horse-power hour (\$14.40 per horse-power hour per month). The installation of Diesel engines and the electric equipment, replacing a poorly equipped steam plant, have resulted in a reduction of 93% of the former power costs. Coal delivered on board at Caleta Buena, costs

29s. (\$6.96) per 2240 lb. The following figures, in pence per quintal (46 kg. or 101.4 lb.) of salitre, may be taken as representative on the basis of 27,000 tons of material in treatment per month (30 days) resulting in an output of 40,000 quintals of salitre for a Tarapaca plant (average figures for 1912), and 22% caliche treated resulting in 100,000 quintals of salitre being produced, per month, in the Antofagasta plant. Costs have gone up considerably, at least 6d. per quintal, in 1913 due to increased cost of labor and lower recovery.

Ocean freight is 1s. 3d. per quintal; previously it was under one shilling.

It is evident from the above that the export tax is a heavy charge. In view of the high-grade deposits having become history, a rational reduction of this tax would mean the possibility of increased activities in the treatment of low-grade caliche and costra. (In 1903 the average grade of caliche treated was 26% NaNO_3 ; in 1912 it was 18%—this refers to the entire industry.) More economical methods might be evolved and larger tonnages treated, with resultant lower costs, but it is questionable as to how the market would absorb the increased output. A lower cost would tend to eliminate the entry of the artificially made (Norwegian) nitrate, and by reason of a lower selling price consumption on a larger scale might be induced where present prices are prohibitive. The prevailing number of oficinas cannot produce salitre f.o.b. at less than 7s. (\$1.68) per quintal (60d. is probably a minimum figure) so that a low price abroad would reduce production, notwithstanding that the largest oficinas have been planned to effect low costs, and possibly demoralize the Norwegian nitrate making. This latter industry, it is stated, will soon be in the position to develop 500,000 ton, hydro electrically, and produce 6,600,000 quin-

tals of calcium and sodium nitrates per annum. In 1912, 1,304,400 quintals—an apparently low output—was produced. The total proposed would be less than one-eighth of the Chilean production for 1912. Its effect on the Chilean product would not be serious in view of the latter's yearly increases. The Norwegian nitrate cannot be shipped great distances. The local demand exceeds the supply hence there is no necessity for long transportation, and must be produced close to the point of demand as it is more hygroscopic than the Chilean nitrate and readily becomes a pasty mass. It cannot be handled in sacks and is packed in wooden barrels wrapped in strong paper.*

The following figures of comparison between salitre and the two most important artificially made fertilizers are of interest:

| | Nitrogen, % | Ratio of cost per unit of nitrogen. |
|-----------------------------------|----------------|---|
| Ammonium sulphate | 20.5 | 1.07 |
| Salitre (Chilean nitrate) | 15.5 | 1.00 |
| Norwegian (calcium nitrate) | 13.0 | 1.15 |

The Southern Chemical Co., at Nitrolee, South Carolina, may produce calcium nitrate, using the Paulin process, at the rate of 50,000 quintals per annum.

Agua Santa Railroad

The Agua Santa railroad serves 16 oficinas besides the six of the Company, not including the one just completed, the Irene. The locomotives, which are of the Baldwin type, haul a train usually made up of 20 cars, each carrying on an average of 5.5 tons (metric), or 55 bags, of salitre. The line has an almost continuous down grade from Agua Santa to Caleta Alta; the ride in the coach, at the end of a train, with the frequent sharp curves to negotiate, is a memorable one producing all the inward distress of seasickness. Alongside of the track is a 3-in. pipe carrying distilled water for the locomotives. About 865,000 gallons of distilled water and 500 tons of coal are consumed monthly by the locomotives. At Caleta Alta are well equipped machine and repair shops, roundhouse, etc., also storage tanks for petroleum. Telegraph and telephone lines supplement the equipment. A sufficiently large rolling stock is always kept on hand. The locomotives are 21 tons and are run in a series of five or six trains at intervals of from 500 to 1000 ft. The loaded nitrate cars are switched to the head of an incline upon arrival at Caleta Alta, and hooked singly to a one-inch cable, which is controlled by a specially designed drum and brake in the head house. The wear on the cable is severe, although passing over rollers; its average life is 300 days. The vertical descent is 2440 ft. to the

pier at Caleta Buena, the track varying from 22 to 32° pitch. There are three inclines, each double tracked (30-in. gage), divided into three divisions of about 800 ft. vertical lift each, and from 1440 ft. to 2340 ft. long on the incline. A down trip, including hooking and unhooking at the two intermediate stations also at the head and foot of the incline, takes approximately five minutes; the actual descending time is less than half of this. In an average day's run (of 11 working hours) 120 loaded cars are handled; a record run of 250 cars has been made. The cost of handling is 1s. (24c.) per ton. The up cars are loaded with supplies.

The sacks are sampled in the yard, which is a shed of considerable extent so as to permit the proper sorting out of the various companies' products, by a government official, who also keeps track of the shipments made. A narrow scoop, similar to a cheese tester, is inserted in every bag and the resulting sample reduced and divided into three bottles which are duly sealed. Each company receives its respective sample, one is kept by the official, and the third is held for umpire. Nitrate under 95% NaNO_3 is penalized according to the lack of NaNO_3 ; 1% of the price being deducted if under 95% and over 94%, 3% additional if under 94% and over 93%, and so on with increasing penalty; nitrate above 95% NaNO_3 is contracted for to contain more than 96% nitrate, 'double refined', and less than 1% salt impurities. This quality generally brings 3d. to 4d. more per quintal than the 95% grade, but the penalty for non-fulfilment is much higher than for the 95% material. The sacks are loaded into launches, by means of chutes, and taken alongside of the receiving ship—usually a sailing vessel—at a cost of 0.72d. (or 1.44c.) per quintal. The loading capacity at Caleta Buena is about 2000 tons per day, when three or four steamers or sailing ships are loading at one time.

Freight Rates

Frequently the incoming boats bring coal from England or Australia, so that low freight rates prevail and competition is keen for the outgoing nitrate freight, which is 27s. (\$6.48) per ton, and was formerly 20s. (\$4.80). In 1912, 642,800 tons of coal and 206,362 tons of oil were consumed in the entire industry. Chilean coal is much lower in calorific quality than the foreign coal and none is used in the nitrate industry. Notwithstanding that more than a million tons is produced annually, it is necessary to import over one and a half million tons to supply the consumption of the railroads, steamers, and industries. Petroleum is brought from northern Peru in tank steamers, which discharge to the 6000-ton shore tanks through a 6-in. pipe-line, with flexible joints, that is supported by floats. The specific gravity of the oil varies from 0.861 to 0.884. A ton of 2240 lb. is usually figured as 305 gal., but this depends on the specific gravity. About 5000 tons of petroleum is received per month at Caleta Buena at a contract price on board, which is variable, but 40s. (\$9.60) per ton might be

*This statement appears contradictory. Later information not obtained from the quarterly reports of the Nitrate Propaganda Association is as follows: "Norwegian nitrate carries an excess of lime and is not deliquescent or only slightly so. It is packed into tins for transport. As a fertilizer it has the advantage of leaving lime in the soil, which is an advantage in clayey soils."

an average. The cost of unloading is 5 centavos Chilean (1 cent U. S.) per quintal. From the tanks the oil is pumped to Caleta Alta, as already explained, at a cost of 2 pesos Chilean (40c.) per ton, delivered in the upper tanks (2c. per 101.4 lb.). A distilling and ice plant forms part of the Company's equipment in the port. Water is sold at two centavos Chilean (less than half a cent U. S.) per gallon for local use and Caleta Alta, and alongside of ships at 6 centavos Chilean (slightly over 1c. U. S.) per gallon.

A Large Tank Excavation

An engineering feat of some importance has recently been completed at Mortlake, Sydney, New South Wales, for which it is claimed that in some respects it is unique, namely, the excavation from solid rock of a huge gasometer tank for the Australian Gas Light Co. The gasometer when completed is to have a capacity of 12,000,000 cu. ft. of gas, but its completion is not anticipated for a couple more years. The water-tank is 945 ft. in outside circumference, 50 ft. deep, and 9 ft. wide; it is said to be the third largest in the world, and the only one excavated in rock, according to the *Australian Mining Standard*. The quantity of rock (sandstone) to be removed was 12,000 cu. yd., and the entire work has been carried out without the use of explosives, that being a necessary condition imposed by the proximity of two gasometers in actual use. The work has been in hand less than six months, the monthly average being about 2000 cu. yd. Besides the rock, and before the rock-cutting could be commenced, ploughs and scoops were employed to remove 35,000 cu. yd. of earth, and the recent heavy rains added to the contractors' task the necessity of pumping out a million and a quarter gallons of flood water. The rock-cutting was done by a Siskol type channeling machine. A channel a few inches wide is cut round the piece of rock to be taken out. Holes of about a foot in depth are drilled along its length, into which two knife-like blades of steel are inserted. Between these 'feathers', as the plates of steel are called, a plug, or wedge, is placed. A man passes along the line of holes and taps each plug with a hammer, and comes back on his tracks, tapping all the while, when the mass of rock suddenly breaks along its entire length. The stone is then cut crossway into blocks, some of which weigh four tons, and the traveling crane, running on rails around the excavation, drops a large iron claw into the tank and carries off the rock, piece by piece, to the dump.

Tunnel-Driving in India

An irrigation canal to water a maximum of 448,895 acres of land has recently been completed in the Punjab district of northwest India, at a cost of \$6,390,000. It has a length of 150 miles, of which 11,235 ft. was a tunnel through the Malakand hills. The aqueduct traverses wild and rocky country, and 167 gulches, from 20 to 100 ft. deep, are crossed. The tunnel is

the second longest in India, has a cross-section of 13½ by 18 ft., and has a capacity of 2420 cu. ft. of water per second. The grade is 1 in 215. Work was started in March 1910 with a Temple-Ingersoll electric-air rock-drill. Ten of these were then used at each end of the tunnel, but after a long trial were discarded in favor of a compressed-air plant. Rock cut was a tough and hard muscovite granite, which quickly blunted the best steel. Three shafts were sunk for ventilation, unwatering, discharge of rock, and opening more faces to work at. An average of 400 drills per day were sharpened. In each heading 16 holes were drilled, also 14 in the sides and bottom. These were from 5½ to 7 ft. deep, and it took from 10 to 16 hours to drill a round of 30 holes. Blasting and removing rock occupied from 5 to 8 hours. An advance of 4 to 6 ft. was made each blast. Nobel's blasting gelatine and Monobel were used. The cost was 24c. per cubic foot of rock removed. According to *The Times*, the originator of the scheme was Sir John Benton.

Progress at the Broken Hill Proprietary Co.'s Steel Plant

At the end of April 1914 the state of construction at this Company's iron and steel plant at Newcastle, New South Wales, was as follows: Pile-driving is well in hand. Concrete foundations for the blooming mill, blooming-mill engine, blooming-mill tables, and the 66 coke-ovens are completed. The open-hearth building and ore bridges' foundations are in progress. Dredging the waterfront and reclamation of swampy land is proceeding. Large coal-bins, with conveyor belt attachments, are complete and ready for work. The blast-furnace construction has reached the last ring. At stoves No. 3 and 4 the dome is bolted on and is being riveted. Stoves No. 1 and 2 are up to their full height and ready to receive the dome. At the coke-ovens, the foundations having been completed, one of the permanent tracks has been put in, and the erection of the base of the ovens is in hand. The 15 gas-producers have been riveted together, and a large amount of similar work on accessories of the blast-furnace plant carried out. Three generating sets in the powerhouse and the lighting unit have been erected. One of these generator sets is now running regularly, supplying the power required for construction work. Two steamers are to arrive with machinery weighing 11,000 tons in all.

In March, at Broken Hill, there was mined 25,414 tons of ore. The concentrating plants treated 23,400 tons of crude ore, and 19,591 tons of tailing was re-ground, together producing a total of 4570 tons of lead concentrate and 5320 tons of slime. In the zinc separation (flotation) plant, 6450 tons of zinc concentrate was produced, assaying 46.56% zinc, 6.82% lead, and 12.91 oz. silver per ton. The sulphuric acid plant made 502 tons of strong acid.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

The Rand Banket

The Editor:

Sir—I must apologize for delay in accepting the invitation to join in the discussion on the valuable paper in which Mr. Horwood re-advances that protean hypothesis—the infiltration of gold into the Rand Banket.

Mr. Horwood's memoir opens with an important contribution to the pseudomorphic nature of the pyrite in the banket. I naturally welcome his full treatment of this subject, as I advanced this conclusion in February 1907 and then figured two pebbles, which, from their *dreikanter* form, I interpreted as pseudomorphs after wind-worn pebbles; after consideration of the various original materials available, I concluded that they were pseudomorphs after ironstone, and that opinion still seems to me the most probable for the cases I had under consideration. I also held that many of the seams crowded with pyrite were pseudomorphic after black iron-sand. The evidence for that seemed clear from the many sections of these layers which I had the opportunity of examining in different Rand mines. Their arrangement agrees exactly with that of the black iron-sand in modern placers.

Mr. Horwood (Fig. 25 and 26, p. 770) extends the pseudomorphic origin to much more of the pyrite, and perhaps goes somewhat too far; for Messrs. Hatch and Corstorphine have a strong case for their view that many of the pyritic nodules are concretionary. Like most concretions, the nodules probably represent the segregation of material already present in the deposit. The analogy drawn by Mr. Horwood between these pyritic and flint nodules tells against his view of the introduction of the pyrite by infiltration from outside. Flints are formed by the segregation of the silicious spicules and grains scattered through the chalk, and not by the infiltration of silica from without. The vertical joints in the chalk which are filled with flint show, it may be noted, that when material has traveled even a short distance in solution the old drainage channels are easily recognized; and yet they are not seen in the Rand.

The pseudomorphic nature of the pyrite pebbles does not seem to help the infiltration theory. On the contrary, it removes one of the difficulties in the placer theory as stated by G. F. Becker. The fact that some of the pyrite pebbles are pseudomorphic no more proves that their materials came from outside than the presence of flint nodules in chalk proves their silica was introduced by infiltration.

Mr. Horwood advances the infiltration theory in a somewhat new and more definite form; for he claims

that the gold was introduced "during or after" the deposition of the dolomites (p. 1010) which lie at the base of the Transvaal System of Molengraaff or Potchefstroom System of Hatch and Corstorphine. His conclusion seems contradicted by the fact that lumps of auriferous banket occur in the Black Reef conglomerates; and unless that well known fact be disproved, it follows that the gold was present in the banket before the deposition of the Black Reef, and consequently long before the formation of the dolomites.

Mr. Horwood's paper contains many interesting and new facts; but many of them increase the difficulties of the infiltration theory. He rejects, for example, the attempt to explain the restriction of the gold to certain narrow seams by the precipitating effects of carbon in them; Mr. Horwood regards the carbon as injected and not as an original constituent. Its quantity certainly appears too small to have had the effect that has been assigned to it; and if it were due to intrusion from some outside area, it would be expected to occur in the fine-grained beds for the same reason that oil pools are found in the 'oil sands' and not in the adjacent conglomerates. Mr. Horwood therefore rejects the most plausible attempt to remove the difficulty of the concentration of the gold in the layers of conglomerate.

He has graphically described the main facts in the Rand goldfield and shown how different it is from any lode-mining field. For its gold occurs in a series of ancient shingle beds extending for 60 miles in length; these beds are made up mainly of pebbles of vein quartz; the conglomerates and their associated sands and shales were deposited during the denudation of a country composed of schists which had been invaded by granites; the intrusion of the granites had formed abundant quartz veins, fragments of which form the conglomerates; the quartz pebbles are associated with the materials which are the natural residues from such quartz veins, including gold and platinum, diamonds, small quantities of copper, lead, and zinc ores; the banket also includes grains of iridosmine and chromite, which Prof. R. B. Young, though an advocate of the infiltration theory, claims as detrital in origin (and Mr. Horwood's answer to Professor Young's arguments on this point does not seem convincing); the most conspicuous silicate is chloritoid, a mineral species which is usually developed by pressure and is not characteristic of lode formations; all the materials of the banket are such as might be expected in shore deposits due to the denudation of the country along which these beds were formed. All these features, as well as the distribution of the gold, its concentration in the beds of coarse-grained, well rounded conglomerate that show the influence of long continued scour by water, and the poverty in gold where the pebbles are angular and the beds show no such traces of long continued water wear are consistent with the detrital origin of the beds and their constituents.

It is difficult to get an absolute test between the infiltration and placer theories. Thus in my paper I

referred to the question whether the gold occurred in shoots or patches. The distinction between these is difficult of definition. I referred to the question at some length because the claim had been made, in support of the infiltration theory, that true gold shoots occurred on the Rand. I examined the best known of these occurrences and showed that it was not a shoot of gold in a widespread sheet of material, like a shoot in a quartz lode, but a simple band of conglomerate in an old channel, and the ore was bounded on each side by quartzite.

A true ore-shoot must have four characteristics: (1) the orebody must be continuous and elongated in form; (2) its boundaries must be fairly well defined, though the passage from ore to barren lode may be gradual; (3) these boundaries are not the margin of the lode, but are due to some change in a continuous lode—for a pipe vein is not a shoot; (4) the distribution of the ore was determined by mechanical concentration and not chemical precipitation. Judged by the third characteristic, the oft-quoted ore-shoot at the Van Ryn has no title to that claim.

Mr. Horwood's interesting illustration of the distribution of the rich and poor material in his figures 25 and 26 (p. 770) correspond, it may be remarked, better with the patchy distribution of gold in a placer deposit than with shoots in a lode.

Mr. Horwood summarizes his list of arguments in favor of the infiltration theory as follows (p. 1005): (1) The great depth to which the profitable ore extends; (2) the dryness of the mines in depth; (3) the abundant water-ways by which mineralizers "could have ascended"; (4) the crystalline character of the gold; (5) the occasional association of the gold with vein quartz; (6) the close association of the gold and pyrite; (7) the occasional presence of calcite, tourmaline, galena, blende, copper pyrite, pyrrhotite, iridosmine, and other metals of the platinum group; (8) the pseudomorphic origin of the pyrite pebbles and their shape and association with rich ore; (9) the distribution of the gold.

1. The first of these points is one of those in which Mr. Horwood's paper strengthens my doubts of the infiltration theory. He shows, from the evidence up to date, that a steady reduction in the grade of the ore with increasing depth has not yet been proved.

There is no doubt a fall in the grade milled, but that does not prove any fall in the actual grade of material in the mine; for owing to the remarkable success of the Rand mining engineers in lessening working costs, lower grade material is now being mined which was formerly left underground. The connection of the fall in grade with the increase in the tonnage milled may be illustrated by the diagram, Fig. 1. Mining, moreover, of course started where the richest ore occurs at the surface; and these mines would naturally become poorer as they approach the margin of these richer areas. Mr. Horwood's summary of the evidence shows that the Rand as a whole displays no such average decrease of actual grade in depth as

there is in all great goldfields. On the infiltration theory, we should expect such a fall; for the deposition of the gold would be more concentrated near the surface where the physical and chemical conditions altered more rapidly.

2. The second point, the dryness of the mines in

FIG. 1. DIAGRAM SHOWING THE FALL IN GRADE ACCOMPANYING THE INCREASE IN QUANTITY MILLED SINCE THE RESUMPTION OF MINING IN 1902.

depth, would apply equally well to some coal mines, which might be represented as lodes due to bituminous infiltrations. In fact, all the arguments for the infiltration theory could be used to explain coal seams as due to bituminous infiltration.

3. Mr. Horwood tells us that there are abundant channels up which the mineralizing waters "might have come"; but we are still without actual evidence of channels up which such waters did come. Mr. Horwood quotes instances in which the dikes have had an apparent influence on the banket, and, as he says, I quoted various instances of the same sort. But I regarded those as coincidences; for assay plans from many parts of the Rand showed that in a very much larger number of cases the dikes were not associated with any change in the distribution of the gold. Kessler and others, after very careful consideration of this question, had come to the conclusion that, in spite of occasional exceptions, the overwhelming balance of evidence shows that the dikes have had no influence on the richness of the adjacent ore.

If the gold had been introduced by infiltration, very many actual channels ought to have been discovered. But there is no evidence that any one of them has ever been found, except in the case of the small secondary veins which were formed after the banket.

One of the most important features of Mr. Horwood's paper is his series of valuable photographs showing the microscopic structure of the banket. They show that the banket, in its microscopic characteristics, is quite unlike any known lode. Lodes formed by infiltration, unless deposited in a fissure, usually show a gradual passage from the country rock through a silicified stage, into sheets of vein quartz; but in the banket many of the richest samples have been no more altered than barren samples. As the matrix of the banket is composed mainly of grains of silica, it would have been readily altered into vein

quartz. The matrix of even the richest Rand ore is, however, often practically unaltered. I have studied microscopically the quartz veins from four continents, and I know of no lode of rich gold ore in which the matrix has not been greatly altered, although it may, under suitable illumination, show traces of its original structure.

4 and 5. The fourth argument—the crystalline character of the gold—is part of the placer theory, according to which the gold has been redissolved and redeposited during the cementing of the banket. The occasional gold quartz veins have no bearing on the main question, as they are secondary products of the same period. They are only of historic interest.

6. The close association of gold and pyrite is not constant: some rich ore is poor in pyrite and some poor ore very rich in it.

7. The seventh feature, the presence of the materials enumerated, is fully consistent with the placer theory, for most of them must have been present as detritus in the pebble beds, and the rest (the diamonds, platinum, and iridosmine) are more easily thus explained.

8. The eighth, the pseudomorphic origin of the pyrite pebbles, was originally advanced to remove a difficulty from the placer theory.

9. The distribution of the gold, its limitation in paying quantities to the beds of water-worn banket, and its absence from the beds of equally permeable 'bastard' reef above and below the rich seams, are facts also consistent with its detrital origin.

Mr. Horwood's arguments for the infiltration theory appear to be not only consistent with the placer theory, but to tell in its favor.

The great quantity of gold in the banket is no doubt unique, but it is also unique for a lode field, and the elastic theory most readily explains this feature. The formation of a goldfield is a process of concentration of a once diffused material. The placer theory adds an extra process by which gold, after a first concentration in the reefs of the metamorphic zone beside the Rand, was further concentrated during the denudation of the country.

The placer theory gives a simple, reasonable, and natural explanation of the origin of the gold, for it attributes its source to the vast quartz-lode series that existed on the Rand before the formation of the banket; the infiltration theory, on the other hand, introduces the gold from a hypothetical and improbable source, along solution channels of which we still have no evidence, and, according to Mr. Horwood's version, at a date long after the banket had received its gold.

J. W. GREGORY.

Glasgow, Scotland, May 5.

The Editor:

Sir—The articles by Mr. Horwood and the resulting discussion have brought out much that is of interest to students of ore deposits. The thesis that the

gold in the Rand banket is of later origin and was introduced as an after-effect of eruptive activity in the region, has been placed in much stronger position than ever before. That the argument made by Mr. Horwood is not wholly convincing to such competent students of the deposits as E. T. Mellor and J. W. Gregory, heartens those of us farther away who still find unanswered questions. It may be freely conceded that the pyrite 'pebbles' are due, at least in large part, to replacement; Mr. Horwood's painstaking researches having brought out convincing proof. It is less certain that this replacement took place long, geologically speaking, after deposition of the sediments, or that the iron, sulphur, or even the gold, was introduced later. The amount of iron involved, though no figures are given, would not seem greater than is commonly found in conglomerates and sandstones derived from pre-Cambrian schists and gneisses. Neither would the necessary sulphur seem to form an exceptional draft upon the powers of sedimentary processes, account being taken of rearrangement of material in the beds; and as to the gold, the great supplies have always come from placers. In certain Cambrian gold-bearing conglomerates in the Black Hills of South Dakota studied by J. D. Irving,¹ the same problem is involved. There, as on the Rand, gold and pyrite are generally distributed through the beds worked, and there are local enrichments. Mr. Irving found that much of the gold was detrital and held that the original sediments contained iron. The formation of the pyrite, according to him, represented action subsequent to deposition and was accompanied by enrichment of certain areas in the conglomerate. Original sedimentary process might, it is true, be appealed to in explanation of such enriched parts of the conglomerate. Take for example the gravels now being dredged at various points along the Sierra foothills in California. In these, gold occurs distributed as on the Rand; that are definite thin beds of gravel, corresponding to the 'reefs' in a thick series of sand and gravel, contain the workable gold; the profitable beds are miles in extent, and within each workable area there are rich and lean portions, often in fact definitely marked pay-streaks. The California placer deposits are not so rich as the Rand bankets, and they are not so thoroughly cemented, but at least they are analogous to the possible original fossil placers that have been assumed by others to have been what F. L. Ransome would call the 'prot-orebodies' of the Rand.

The California placers occur at the embouchure upon the plains of rivers traversing auriferous areas. Essentially they are delta deposits. In this connection it may be noted that Mr. Irving found the Cambrian conglomerates already mentioned to be littoral sediments. Examination of fluvatile placers, the usual type, shows that long, narrow, and usually crooked pay-streaks are the rule. The map of no river placer of which I know resembles the most interesting stope

¹U. S. Geol. Survey, Prof. Paper 26, p. 98 *et seq.*

maps of the Rand which Mr. Horwood has given us.

T. A. Rickard has pointed out the differences between the Rand bankets and the beach gravels at Nome, and if T. M. Gibson's map² of the Third Beach line be compared with the Rand stope maps, it will be seen that there is practically no resemblance in form. Indeed, the Nome pay-streak is characteristically long and narrow, as is one formed by river action: it differs in being straight rather than crooked. It is to be remembered, however, that the Nome gravels contain gold concentrated and reconcentrated by active waves on a long gently sloping beach line with shallow water. These conditions would seem most favorable to bringing the gold into the narrowest possible streak along the shore. The California placers, on the contrary, were formed where there is little evidence of wave action. They are alluvial cones formed in quiet water, or even possibly in flood times above normal water level, just as material is being spread over their tops now. The point is that there are types of placer deposits that show just such distribution of gold as on the Rand, and further, that at least one fossil placer of this type is known. That there has been redistribution of the gold in the placers, proceeding furthest on the Rand and least in the very modern California deposits, is quite in accord with the ordinary history of rocks, and does not require, though it may be facilitated by, unusual geological agencies such as the intrusion of eruptive rocks.

Assume, on the other hand, that the gold was, as Mr. Horwood contends, introduced later as an incident of igneous activity, where is any analogous deposit? The nearest correlative that I have seen is, again, in the Black Hills, where there are certain 'silicious' deposits also studied by Mr. Irving. These are sandstones mineralized by solutions entering along transverse fissures and cracks. A brief visit to these mines, reinforced by a study of his admirable cross-sections and plans, shows that the result is not at all the same as on the Rand. The gold is localized and is much more definitely related to the fissures through which the solution entered than the Rand stope maps indicate. Briefly, pay-streaks were formed rather than mineralized beds. In the Black Hills the two methods of origin are contrasted, the examples being in beds of possibly the same approximate age as on the Rand, and other conditions including later intrusion of igneous rocks being the same. Mr. Irving has presented only one stope map of 'conglomerate' workings, and I am not personally familiar with these deposits, but so far as evidence at hand goes, the argument from analogy would seem to favor considering the Rand a re-worked placer. Argument from form, it must be confessed, is but one possible mode of approach and does not give a final answer. It may, however, justify an attitude of suspended judgment, even in the face of such evidence as Mr. Horwood has presented.

There is one other point in this connection that warrants a word. Mr. Horwood accounts for the segregation of the gold in certain 'reefs' in the midst of the great sandstones series, by the action of shales or slates in checking the flow of the gold-bearing solutions. This is a common phenomenon, and the argument is sound, but Mr. Horwood finds the gold above the shales where it would accumulate if it were detrital or rearranged detrital gold, and not below, where Mr. Irving found his gold in the Black Hills and where deep-seated solutions would be checked. Among American geologists at least, one of the common tests for determining whether ascending or descending solutions have been active is whether the accumulation is below or above the barrier bed. Is this criterion valueless? It is difficult to see how a special and local efflux of water from dikes could produce the results shown. It would be easy to conceive of these results as flowing from a normal general circulation of underground water acting in the main on material already in the rocks and reinforced locally both as to energy and material by the intrusion of igneous rocks.

Mr. Horwood's evidence relating the gold to the dikes is apparently convincing to those who are in a receptive attitude, or who see all gold deposits in close relations to some igneous rock however small. To others it is as intangible as is much of such evidence. Possibly this is a limitation of the readers in question: possibly not. Time will tell.

I would not close without expressing my high appreciation of the work Mr. Horwood has done. For so busy a man in the midst of other and exacting duties to find time, energy, and enthusiasm for so much research, is inspiring to all his fellow-workers. If some of us fail to find his conclusions entirely convincing, we must needs stand open to the imputation of over-conservatism.

II. FOSTER BAIN.

San Francisco, June 10.

[As Mr. Horwood can devote but little more attention to this subject for the present, this will, except for his general reply now in preparation, close the discussion. The whole matter will shortly be brought together in book form.—EDITOR.]

Magnesite produced by the Anglo-Greek Magnesite Co., Société Hellenique des Mines, and the Hellenic Magnesite Co., operating in Greece, amounts to approximately 110,000 tons of raw, 32,000 tons of calcined, and 4000 tons of dead-burned product per year. California produces about 11,000 tons of raw ore per year. Imports of magnesite into the United States in the year ended June 30, 1913, were 172,595 tons, valued at \$1,727,848.

High-grade chrysotile (fibrous asbestos) was opened about 30 miles northeast of Globe, Arizona, in 1913. Raw asbestos produced in the United States in that year was 1100 short tons.

¹*Mining and Scientific Press*, April 25, 1914.

²*Op. cit.*, plate XI; 'Types of Ore Deposits,' Fig. 14, Fig. 15.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

A pair of 8-ton rock skips can be changed for two 4-deck cages to carry 80 miners each, or *vice versa*, at the Crown mines, on the Rand, in 15 minutes.

Steam-shovel pits often fill with water from storms and other causes, and if no pumps or syphons are available, the shovel feed pump may be used to empty the pit.

Explosives are made in three factories in South Africa, the total manufactured in 1912 being 22,891 tons. Detonators imported numbered 49,415,000, and coils of fuse, 9,943,000.

Men employed in mines, mills, and reduction works of Queensland in 1913 totaled 15,842, against 16,632 in 1912. The death rate in all mines and works was 1.38 per 1000 employed, compared with 1.92 in 1912.

Concentrate treatment at the cyanide plant operated by the companies on Douglas island, Alaska, cost \$3.05 per ton treated, the total from five stamp-mills being 32,546 tons in 1913. The recovery was 97.3 per cent.

Artificial rubber may probably be made from coke-oven gases, according to the president of the Iron and Steel Institute, London. These gases contain the hydrocarbons, the derivatives of which were found in india rubber.

The Foundry at the Alaska Treadwell mine in 1913 produced 1,207,187 lb. iron and 11,802 lb. brass castings. Included in this is nearly all of the mill parts used in constructing the new mill of the Alaska Juneau Gold Mining Company.

Horse-power required for Root's blowers capable of supplying 100,000 cu. ft. of air per minute in a mine, at a pressure of 12 oz. plus the power required to overcome friction in pipes, is 600 to 650 hp., as determined by the length of pipes. An installation of ventilating system for a mine employing 2000 miners would cost under \$48,000, according to G. H. Blekin-sop of the Rand.

A tube-mill is to be installed in the Antelope mill, Rhodesia, to replace 12 grinding pans, which, according to the manager, A. J. Fraser, would not do the work expected of them. In spite of all efforts to increase the duty of the pans, little success was met with. This is a peculiar result. The ore is crushed in two No. 8 Krupp ball-mills, roasted in four Edwards' furnaces, ground in 12 pans, agitated, and filtered in Dehne presses.

The Lonely Reef mill in Rhodesia now consists of twenty 1250-lb. stamps, two 5 by 14, and one 5.5 by 16-ft. tube-mills, four 20-ft. Dorr thickeners, four 8 by 32-ft. Pachuca tanks, and three 50-chamber, 40-in. square Dehne filter-presses. Ore treated in 1913 totaled 58,903 tons, yielding 16,641 oz. gold and 747 oz. silver by amalgamation, and 35,370 oz. gold and 1550 oz. silver by cyanidation.

An interesting tin mineral was found in Butte during the past year and it was first discovered in the Colusa vein, one of the early locations of the district. It has been called colusite, according to C. W. Goodale. A part analysis of one specimen is as follows: Cu, 46.1%; Fe, 1.8%; S, 28.4%; As, 6.5%; Sb, 2.5%; Sn, 6.6%; Te, 3.1%; Au, 7.55 oz.; and Ag, 15.80 oz. per ton; total, 95.0%. The appearance of the mineral in a polished section under the microscope leads to the conclusion that it is complex, perhaps a mixture of stannite, tetrahedrite, a telluride of gold, and other minerals. Ten specimens have been analyzed, including several from the Mountain View mine, and variations in compositions are found, so that further study may show that it is not entitled to a name for a new mineral.

The appearance of high-grade cyanide bullion, after acid treatment and direct smelting of the precipitate, is often impaired by the presence of small quantities of matte which adhere tenaciously to the surface of the gold. With a lower-grade bullion, the matte, if any, generally comes away cleanly on sudden cooling, leaving a bright surface of metal. In other instances, and where the by-product is troublesome, the best method of procedure is as follows: After the fluxed precipitate has been smelted, and the molten mass poured into a pot, only enough time should be allowed for the gold to thoroughly set. The slag-pot is then tilted and the liquid slag poured off. The pot is then inverted, away from the slag, and the button of bullion tipped out. The adhering matte, in a pasty condition, is then cut and scraped off. The matte has a much lower melting point than the bullion, and sufficient time will elapse to allow for the removal of nearly all the matte before it sets. After the gold buttons have been remelted and the metal poured into an ingot mold, and if there is still sufficient matte to cause trouble, then the appearance of the bullion may often be considerably improved by adopting the following method of procedure: The ingot should be tipped from the mold while the bullion is still red-hot, the slag having been pulled away from the surface of the metal with a bent iron rod, when part cooling has allowed the slag to become sufficiently viscous. The surface of the ingot is then rapidly scrubbed with a coarse wire scratch brush. This will remove the remaining slag and matte. The ingot is then placed, while still hot, in a bath of diluted commercial nitric acid. When all action has ceased, the ingot is removed, washed in water, moistened with soda liquor, and scrubbed bright.

Special Correspondence

NEW YORK

UNITED STATES SMELTING COMPANY'S BONDS.—INTERNATIONAL NICKEL, BUFFALO MINES, AND CALUMET & HECLA REPORTS FOR 1913.—PANAMA CANAL AND COPPER PRODUCTION.

The excellent reception which the \$4,000,000 of United States Smelting, Refining & Mining Co. 5% bonds received shows an encouraging tone in the money market. The notes were offered at 98 $\frac{1}{4}$ and mature June 1, 1918. These notes are the only debt which the Company possesses, though it has a contingent liability in \$10,000,000 of the collateral trust notes of the Utah company, which it has guaranteed.

The International Nickel Co. has also made its report for the year ended March 31. The total income amounted to \$6,566,786. The profit balance available for dividends amounted to \$4,792,665. The copper output of the Company was a high record, but the decline in the price of metal prevented the Company from making a record for earnings. The sum of \$1,391,290 was charged off to the property account, against which \$1,324,309 was written off for replacing mineral exhaustion and depreciation. Excess of current assets over liabilities amounted to \$7,384,561.

The Buffalo Mines Co. has also made its report showing a total income of \$982,040 and operating expenses of \$471,835. Dividends during the year amounted to \$660,000, leaving a deficit of \$273,010. Although the tonnage milled was greater than last year, the average silver content of the ore was 7.14 oz. less. This, taken in conjunction with the lower price of silver, made a marked decrease in earnings. The ore reserves from development contained 1,352,900 oz. of silver in ore containing 25 oz. per ton; 707,725 oz. in ore of the same grade is already broken in the stopes. There was 200,000 tons of sand from the mill, containing over 1,000,000 oz. of silver caught by retaining dams. The mill recovery was 76.14%, and the total recovery by milling and cyanidation was 81.5 per cent.

The Calumet & Hecla Mining Co. has made its report for the year ended December 31, 1913, and has resumed reporting the output of its subsidiaries. From its own properties, the Calumet & Hecla produced 45,016,890 lb. of copper during 1913. The average yield was 22.11 lb. of copper per ton, produced at a cost of 14.25c. per pound. The increase, as compared with 9.86c. per pound for the preceding year, is of course due to the difficulties created by the strike. The balance sheet shows a surplus of \$6,553,964. Dividends received from the subsidiary companies were as follows: Isle Royale, \$32,300; Ahmeek, \$539,264; Osceola, \$343,875. The output of the Calumet & Hecla properties is now practically back to normal, since the yield for May was 9,299,507 lb. as compared with 10,765,426 lb. in May of last year. It was generally supposed that the long strike and the consequent cutting down of the supply of Lake copper would have the result of causing consumers to use electrolytic copper instead, and since this is just as good for many purposes, it was expected that Lake copper would show a tendency to lose the premium which it has for so many years commanded as compared with electrolytic. This does not seem to have been the case, however, and Lake copper still seems to be in good demand.

The opening of the Panama canal is apparently to have considerable effect on the copper-smelting situation, and possibly on output. Not long ago the fact was mentioned that the Tacoma smelter was handling a constantly increasing tonnage due to the fact that freight rates from the west coast of South America to Tacoma were better than to the eastern seaboard, and as a result it was not profitable to

ship here. The opening of the Panama canal is likely to change that situation, however, and indeed make it possible to send copper-bearing material from the west coast of the United States to the East through the canal. The report has recently been given out that one of the Western companies has made a contract for the delivery of copper matte from the western coast to the copper refinery at Laurel Hill, Long Island, for \$12.50 per ton, as compared with a former freight rate of \$36 per ton. The production of copper on the eastern coast of the United States will be correspondingly stimulated, and some interesting changes in the general copper-mining situation may develop.

DEADWOOD, SOUTH DAKOTA

ORO HONDO OPERATIONS.—RATTLESNAKE JACK MILL EQUIPMENT. EXPERIMENTS AT GOLDEN REWARD MILL.—WASP No. 2.—HEIDELBERG COMPANY.

Considerable more repair work was necessary at the Oro Hondo mine than was anticipated at the commencement of work by representatives of J. T. Milliken, of Colorado, but everything has now been put in shape and sinking begun. Extra power was found necessary, and to furnish it two boilers of 100 hp. each have been installed. This makes a total boiler capacity of 400 hp. The mine does not require much pumping, so that this equipment should furnish sufficient steam for carrying forward the sinking of the shaft, which it is proposed to continue from the present level, 1050 ft., to the 2500-ft. level. Joseph Carr is manager.

At the Rattlesnake Jack mill, in the Galena district, a complete equipment of Trent cyaniding machinery is being installed. The plant has 10 stamps, with which it is proposed to crush the ore to 6 mesh, and with a Hardinge conical mill sliming everything the capacity will be close to 100 tons per day. Classification will be done in a Dorr classifier. The Trent machinery includes a 16 by 24-ft. agitating vat, a similar sized thickener tank, and two 14 by 24-ft. replacing tanks. Precipitation will be by the Merrill method, and a press of 200-ton capacity is being installed. Work on the plant is being expedited, and it is hoped to have it crushing ore by August 1.

Exhaustive experiments are to be conducted at the Golden Reward mill, in Deadwood, on roasted ore from the Company's properties in the Bald Mountain district, and to facilitate the work a 60-ton tube-mill and three additional tanks, an Akins classifier, and other apparatus are being installed. Part of the ore carries a high percentage of pyrite, and sulphates are formed during roasting which have caused some difficulties, and it is proposed to solve the problem on a working scale.

A Keystone No. 3 traction drill has been received by the Wasp No. 2 company, and considerable prospecting will be started. Recently a skip track was laid to an old cut in the porphyry, and a portion of the mill supply is now of that material, which is said to be giving high returns. The clean-up on June 1 was the largest in several months.

Incorporation of the Heidelberg property, which was promoted as a prospecting syndicate last summer by the Deadwood Business Club, is now proposed in order to furnish funds to complete the development of what is undoubtedly a meritorious prospect. It is proposed to form a company of 500,000 shares having a par value of 25c. each, of which one-half will be placed in the treasury and one-half divided among the owners. The half the owners will receive will be divided equally between the original owners, John Treber and A. T. Roos, and the 50 local people who subscribed to the development fund. Under the plan, then, Treber and Roos will receive 125,000 shares, and each subscriber to the fund will receive 2500 shares. It has been decided to offer to the public 100,000 shares at 10c. per share.

DULUTH, MINNESOTA

DULL TIMES IN THE IRON REGION AND LOWER WAGES PAID.—LINCOLN, CORSICA, AND VIRGINIA MINES.—OLIVER COMPANY'S OPERATIONS.—FIRST-AID WORK.

Conditions are very dull on the Mesabi Range at present. Few mines are working to capacity, and many properties that have a poor grade of ore, or high operating costs, are closed down entirely. This has resulted in throwing a large number of men out of employment, and in one instance nearly led to a riot, which was quelled without any serious consequences. A general cut in wages, amounting to about 5%, was made, surface labor being reduced from \$2.50 to \$2.25 per day. Underground men have been reduced less, and contract prices will be lessened in proportion. As a consequence of the slackness in the mining business, the various municipalities where there are a large number of idle men are planning extensive improvements. A concrete road will be constructed between the villages of Hibbing and Buhl, and a large amount of paving will be put in this season in Eveleth, Mountain Iron, Buhl, Chisholm, Nashwauk, and other towns.

The Lincoln mine, which was drowned out last month, has been drained, and a ditch has been constructed to provide a channel for the large amount of drainage that passes near the property. The fact that the mine is in a depression makes it a difficult matter to control the heavy flow of water which comes in the spring, and occasionally during a heavy rain. This mine is also erecting a new steel head-frame.

The shafthouse at the Corsica mine, at Elba, which was destroyed by fire last month, will be replaced with a steel one, for which plans are under way. The fire is supposed to have been of incendiary origin, and gained considerable headway before discovered, burning from the top down. Timber in the shaft to a depth of about 70 ft. was also destroyed, and it is expected that this timber will be replaced with steel sets. A new timber shaft is being sunk at this property, and a 'rock drift' is being driven from the workings to connect with it. Owing to the hoisting plant being out of commission, the rock from this work is trammed and dumped in an abandoned shaft. This mine is operated by the Pickands-Mather Co., which is also dismantling the Virginia mine. The work of removing the crushing plant is now in progress. This was installed for the purpose of reducing large pieces of hard ore, broken in the pit, to size suitable for the furnace.

The Oliver Iron Mining Co. has removed two of the steel head-frames from the Gilbert mine, and is now removing the third. This is one of the properties embraced in the Higgins Estate lands. The Company has a large number of drills at work on these lands, and it is understood that they are being purchased outright by the Oliver company, payment being based on the results of the drilling. The fact of the head-frames being removed from the Gilbert mine would indicate the abandonment of operations at the property for a term of years, or that it will be operated entirely as an open-pit mine. The Minnewas mine of the Oliver company has recently completed a concrete stack for its boiler-house, and the work of plant construction is being carried on vigorously. The main activities of the Company seem to be concentrated at present on the lands leased from the Hill interests, which leases will be given up at the end of this year.

Mine-rescue car No. 8 recently finished a tour of the Range, giving instruction in first aid to the injured and training in oxygen breathing apparatus at Eveleth, Virginia, Hibbing, and Chisholm. At the end of the trip a meet was held in the ball park at Virginia, and a public demonstration given in first-aid rescue work. About 30 teams took part, and a large crowd was present, evincing great interest in the work. During this trip of the car to the Range, about 300 men re-

ceived training in first-aid work, and about 75 in mine-rescue work. The campaign of education for safety is being greatly aided by this government car, and it is felt that the number of preventable accidents is on the decrease. The various companies are taking active interest in general welfare work. Prizes have been offered for the foremen with the least number of accidents on their shift, and prizes are also offered for the best garden, the best lawn, and the best and cleanest premises, with the result that many places that were formerly filthy are now orderly and sanitary.

Many contemplated improvements are being held in abeyance until business improves. Economy is the watchword, and all work is being done with as small a crew as it is possible to use.

MAP OF IRON RANGES OF MINNESOTA.

The Rowe open-pit mine on the Cuyuna Range has entered the shipping list. The top overburden has been removed by hydraulicking and the balance by steam-shovel. The Company has built 19 cottages for its employees, and the streets of the township have been graded. Each cottage has a cement cellar, sewer, water, and a bathroom. These are rented to the employees for \$15 per month. There are about 10 smaller houses, not modern, which are rented at \$6 per month. Shipments have begun from the Cuyuna mill, Laes, Armour No. 2, and Kennedy mines. Drilling activity continues in spite of general slack business at various iron properties.

BUTTE, MONTANA

IMPROVEMENTS AT THE ANACONDA SMELTER.—CLAIM MAPS.—

HECLA AGAIN PRODUCING.—BUTTE & SUPERIOR MILL RESULTS.

—LITIGATION.—BUTTE & LONDON.—LABOR UNION TROUBLES.

Improvements of various kinds are under way at the Anaconda smelter. The plant for grinding coal to dust for use in the reverberatory furnaces is nearly completed and should be ready for use by July 1. The new slime concentrator, with a capacity of 300 tons per day, is working satisfactorily, and is making a concentrate containing 7 to 8% copper. The big leaching plant should be ready for use within a year. The first unit of 2000 tons will be ready then, but further units will be added just as soon as the initial unit is working smoothly, until the plant is finally increased to a capacity of possibly 10,000 tons per day. The old tailing dumps will be treated, and also the tailing as it now comes from the mills. Reports from the Company for purposes of taxation show a net income for the twelve months ended June 1 of but \$8,613,564. This compares with \$11,446,901 last year, and with \$11,323,498 for the calendar year 1913, as re-

ported to the shareholders: that is, the earnings for this period were about \$2 per share as against \$3 paid.

Some recent changes and advances in the staff of the Anaconda Copper Mining Co. are of interest. The managing director, C. F. Kelly, is confining his attention entirely to executive affairs, turning over the legal department to L. O. Evans, who now becomes chief counsel. The title of the general superintendent, John Gillie, is changed to manager of mines, which has been his actual position for years. In like manner, B. H. Dunshee becomes assistant manager of mines. A new general superintendent has been created in the person of W. B. Daly. The assistant superintendents are as before, namely, Thomas Mitchell and Jack O'Neill.

North Butte also feels the effect of the lower metal market, the income for the twelve months ended May 31 being reported at \$1,294,000, as against \$1,613,046 and \$1,437,777 for the calendar year 1913. This amount, however, is still well in excess of the dividend rate, being equivalent to about \$3 per share as against \$2 paid.

Mining engineers who have been indulging in the rather common practice of copying claims from published maps should take warning that claim maps are generally copyrighted, and that copying them without permission for sale in mine reports is against the law. In a recent case at Butte an engineering firm was awarded damages from defendants who had copied portions of a map without permission.

The famous old Hecla mine, above Glendale, is again in the producing list. Under the able management of the Longmaid family of Helena and their associates, the mine is being resuscitated. A 20-stamp mill and concentrator have been equipped for the property and concentrate is shipped to the East Helena smelter.

The millmen of the Butte & Superior Copper Co. deserve considerable credit for their success with the hard, silicious zinc ores of the Black Rock mine. With the aid of flotation the recovery has now been brought up to 93%, and the concentrate is averaging 54% zinc. Before flotation was used it was difficult to get the concentrate up to 50%, which meant unsatisfactory smelting rates and higher shipment costs. The finding of the Butte & Superior zinc mine was a remarkable thing, but more or less of an accident, as the zinc ores were not predicted. But the remarkable metallurgical successes with the ore are not accidental and are the result of hard-headed, clever experimenting.

Butte is having something of the old-time activity in mine litigation these days. Mine 'experts,' 'practical miners,' 'old-time' prospectors, and ubiquitous lawyers are collected about the courthouse in full force just now. The Anaconda Copper Mining Co. and the Pilon-Butte Mining Co. are disputing over the ownership of certain rich orebodies. The suit is being tried before the district court.

The Rainbow Lode Development Co. is unwatering the shaft of the Butte & London Copper Development Co., preparatory to further exploring the property. The task of unwatering the mine to the 1200-ft. level is no small one, as the natural flow of water is heavy in that section. Bailing tanks and electric pumps are being installed, with a total capacity of 2400 gal. per minute. One of the pumps to be used in unwatering the mine was left on the 800-ft. level when the mine was closed down several years ago. The pump was found in good condition after its long submergence, and will soon be ready for service again.

As mentioned in the 'General Mining News' section of this issue, disaffection is rife in the miners' union at Butte. To all the trouble and damage done on June 13 the city and county authorities offered no serious resistance, making the plea that the miners had a right to do what they wished with their own property. As usual, the mining companies have to be the 'goats' for this internal strife, and the mines will be working but part time until the men settle their differences.

JOPLIN, MISSOURI

H. L. & S. MINE CHANGES OWNERSHIP.—UNUSUAL LEAD DISCOVERY.—NEW MILL PRACTICE.—ZINC AND LEAD ORE PRICES.

The H. L. & S. mine, operated by Schuck, Larkin, Hill, and Norton at Lawton, Kansas, has been sold for \$60,000 to Walter S. Watson and Charles Pointz, of Joplin, and L. Kirk of Maysville, Kentucky. The property occupies a lease of the Eastern Lead & Zinc Co.'s land, and was the second mine opened in the Lawton district, which has been productive for only about three years. Edward Goettel, who will manage the H. L. & S., intends to increase the capacity of the mill from 100 to 150 tons; and mining, which has been done to a depth of 120 ft., will be lowered to 160 ft., and a high stope will be taken up.

On the eastern portion of the Eastern Lead & Zinc Co.'s land, at Lawton, Kansas, a new shaft has opened lead ore at from 40 to 50 ft., and driving will be started. The ore will be trammed to the mill, 1000 ft. to the west, which is already being supplied with ore from two shafts. The fact that Lawton has been almost exclusively a producer of zinc ore causes the lead discovery to be of unusual interest. Not only is the lead ore known to exist in the immediate vicinity of the shaft, on all four sides of which the ore is exposed, but it is shown in several drill holes nearby. The 'dirt' is of exceptional richness, yielding 30% galena. It occurs in a hard blue flint, and no timbering will be required, as the ore stratum is overlain by hard limestone. The galena is high grade, running better than 80% metallic lead.

Within the past week or two some important developments have been made on the Robinson & Coleman land, in the Neosho river bottoms, two miles northwest of Miami, Oklahoma. This is a virgin district, several miles from the mines of the main Miami camp, is of high grade, some of it running as high as 61% metallic zinc. Galena also is plentiful. A concentrating plant of 150-ton capacity was erected by McConnell & Barnes on this land before they sunk their shaft into ore. So many drill-holes have been put down into the rich ore that they felt confident of opening it in quantities sufficiently extensive to warrant the operation of a mill. While their mill was under course of construction they were sinking their shaft, and this has now broken through into good ore.

The J. B. Jameson Mining Co., which is interested in mining in the Joplin district, has begun the construction of a 150-ton concentrating plant in Taney county, miles from the nearest developed area. The new property lies near the little town of Melville, and while lead ore was occasionally found by farmers in digging wells, no effort was ever made to mine on an extensive scale until the present company took over their present property. A former company had sunk a shaft only a short distance; this was extended deeper by the Jameson company, and what appears to be an extensive fissure vein of about 6% zincblende was cut. This is now opened by several drifts, and the ore is shown in a number of different headings.

At the B. & H. mill, operated by the Granby Mining & Smelting Co., on its land at Chitwood in the northwest part of Joplin, an experiment in separation of slime from the ore is being tried. A dewatering screen of 1¼-mm. mesh is used to separate the slime from the coarse ore before the ore reaches the rougher jig. All dewatering devices in the district at this time are used after the chats have passed through the rougher and the cleaner jigs. The operators of the plant believe the innovation will materially increase the efficiency of the jigs and will remove the bulk of sludge ore before it passes to the cells. They claim the process will eliminate the necessity of using such a heavy flow of water over the jigs as heretofore.

Zincblende prices are lower throughout this district than

for the corresponding week of 1913. The best grades sell for \$43 on an assay basis of \$40 per ton for lots running 60% metallic zinc. The basis offerings range down to \$37. Calamine sells for \$23, basis of 40% metallic zinc, and lead ore at \$46, 80% metallic lead. For the corresponding week of 1913, blende brought \$43, basis; calamine, \$21; and lead ore, \$52.50 per ton.

HOUGHTON, MICHIGAN

ENERGY DISPLAYED AT THE COPPER MINES.—CALUMET & HECLA, ISLE ROYALE, WHITE PINE, WINONA, MASS, VICTORIA, AH-MEEK, WOLVERINE, AND KEWEENAW MINES.

With the termination of the strike, and the resumption of old conditions, the mining companies are again devoting their energies to the economical production of copper, and the campaign for lowering the cost per ton of 'rock.' Calumet & Hecla officials are giving considerable attention to placing their numerous subsidiary companies in the best possible condition, and are achieving great success. The Isle Royale continues to warrant its name of a real mine, won after 50 years of uphill struggling, and developments in its extensive territory to the west, near the old No. 1 shaft, look still more promising. Many Houghton people are pleased at Isle Royale's improvement, and it is thought that its future is bright. Another Calumet & Hecla subsidiary, of which the future is liable to be surprising, is the White Pine, alone in the Porcupine Mountain district. This mine is on a new type of formation from all other Michigan copper mines; its copper, fine and flaky, occurs in shale or sandstone known as the Nonesuch formation. The mill, on which construction has been started, will be different from other Lake Superior

COPPER SMELTER OF THE COPPER RANGE CONSOLIDATED, PORTAGE LAKE, NEAR HOUGHTON, MICHIGAN.

mills, as elaborate experiments on White Pine ore have shown that the flaky copper is difficult to save, being more friable and less tough than the general run of native copper. Some hitherto unprofitable mines on the south end of the copper range are showing encouraging improvement, especially the Winona, which has the advantage of an excellent and up-to-date equipment, and which may possibly be on a paying basis soon, after 16 years of assessments. The Mass company perseveres, and is finding more copper and perfecting its organization; its management being good. The Victoria, where the famous Taylor compressor furnishes air for running the mine and mill at practically no cost, is making a few discoveries of copper occasionally. This mine is almost as obscurely situated as the White Pine. On the north end of the copper range, the Ahmeek is getting its fine equipment and rich stopes into order again after the strike. Old Wolverine, which was such a steady 'gold mine' for so long, is extending its life a little by finding copper in the foot-wall of old workings. Still farther along in the Ashbed country, the Keweenaw Copper Co. continues to test out T. F. Cole's faith in his boyhood district, by extensive diamond-drilling, and is said to be making favorable progress.

PORCUPINE, ONTARIO

DOMES YIELD AND FUTURE POLICY.—HOLLINGER PROFITS.—DOME LAKE AND DOME EXTENSION MINES.—MCINTYRE YIELDS.

During April the Dome mill treated 14,770 tons and produced bullion valued at \$97,455. Official figures for the May production have not yet been published, but it is understood that the amount treated will be slightly over 15,000 tons, while the grade will be somewhat lower, averaging about \$5 per ton. According to the statements given in the annual report, this latter grade is about what should be expected from future operations. At the annual meeting held in Toronto on May 26, the president stated that the question of dividends, together with the policy of future enlargements and the method of financing the same, would receive the most serious consideration by the directors as soon as they were possessed of sufficient information to justify action being taken. Despite the many rumors to the effect that a dividend would shortly be paid, it is altogether probable that such disbursement will not take place for some time to come.

During the past month or so, Hollinger stock has been slightly depressed, due, it is believed, to the fact that the Anglo-French Syndicate has been liquidating some of its holdings. About a year ago, this Company purchased 20,000 Hollinger shares, but its recent report would indicate that a large portion of this has been sold. The stock has been much stronger recently, partly on account of statements to the effect that the dividend would shortly be increased from 3 to 5% every four weeks. It is well known that the Hollinger company will not consider an increase in the dividend rate until such time as it has accumulated \$1,000,000 cash. It is hardly likely, however, that the rate will be increased from 39% per year to 65% per year. The last annual report showed ore reserves having an estimated value of \$13.70, and it is understood that while development on the property is extremely satisfactory, and has been successful in opening large bodies of ore, the grade is lower than was estimated in the annual report. The increased production will no doubt offset the inevitable drop in grade, but any material increase in the dividend rate is hardly to be expected for some time to come. In addition to this expected drop in the grade, the large tonnages being developed will shortly justify further extensions to the plant, and this will probably be provided for out of current profits.

At a special meeting of the shareholders of the Dome Lake company, a by-law was passed authorizing the sale of 100,000 shares of treasury stock at 50c. per share. This stock will be offered to the shareholders, but as the market price is below 50c., the greater portion of it will probably be taken by the Temiskaming & Hudson Bay company, which already has control. The proceeds from this sale will be used for the erection of a cyanide plant, and to enable the Company to carry on a more extensive scheme of underground development. The recent report of the manager covering the last five months, states that several veins have been cut in the underground workings, but the gold content is low. He considers, however, that the possibilities of the discovery of further bodies of commercial ore are extremely promising and is optimistic as to future development.

A meeting of the shareholders of the Dome Extension Mining Co. has been called for June 19 to consider a by-law authorizing the sale of 199,993 shares of treasury stock at 10c. per share. This property adjoins the Dome mine, and it is calculated that the extension of the Dome orebody runs into the Dome Extension ground. A considerable amount of work has already been done on another orebody, and has succeeded in opening a considerable tonnage of ore, the grade of which is, however, too low to permit of economical operation at the present time. It is not unlikely that this ore will be profitable some time in the future.

General Mining News

ALASKA

CORDOVA

Since January 1, the Mother Lode mine has shipped 525 tons of ore to the Tacoma smelter, yielding 561,484 lb. copper, and \$915 oz. silver, worth \$69,429 net.

NOME

The steamer *Corwin* is inside the ice-pack, and her passengers were landed. The *Victoria*, *Senator*, *Elihu Thomson*, and *Bear* were waiting on June 13 in the ice, eight miles from Nome, for a chance to make a landing. About 1000 passengers were on the *Victoria* and *Senator*.

VALDEZ

On July 1, an automobile mail and stage will be started from either Valdez or Chitina to Fairbanks. The government is to send most of the interior mail overland this summer, instead of by the Yukon river route. Fourteen feet of ore is being mined in the Granite property. A run of 13 days with a Lane mill yielded \$6000 gold. W. R. Millard is superintendent. Three miners who spent the past winter in the Nelchina district arrived in Valdez on June 4. Sluicing was in progress on eight claims, and 'pay' has been found on five different creeks. An output of \$250,000 is expected this season. A contrary report by C. Artal, who reached Seward after being at Nelchina, states that the camp is dead and most of the creeks are poor.

ARIZONA

COCHISE COUNTY

(Special Correspondence.)—A 2-jig concentrating plant, with a capacity of 30 tons per day, has been completed here by the Hermitage Mining & Milling Company.

Hermitage, June 11.

MARICOPA COUNTY

(Special Correspondence.)—Ranchmen in from the vicinity of Mesa, 16 miles from Phoenix, report a gold discovery made 25 miles northeast of Mesa and 5 miles west of the McDowell range. A large tonnage of \$16 ore is showing on the surface. The vein, which is in granite, also contains bismuth. About 20 years ago, O. D. Merrill staked a claim in the same district, and after these many years has returned. A number of claims have been staked.

Phoenix, June 11.

MOHAVE COUNTY

More rich ore is said to have been opened in the Tom Reed mine. The first week in June the Gold Road yielded gold worth \$15,500. A 60-ton smelter is to be erected at the Swastika mine, near McCracken, to treat lead-gold-silver ore. W. H. Smith is in charge. At a depth of 100 ft. in the Arabian mines, in the Union Pass district, a large body of silver ore has been cut. This property is under option to the Mines Company of America. The Frisco mine, nearby, contains gold, while the Sheeptail and Catherine contain silver.

YAVAPAI COUNTY

At the mine of the Aztec Mines Co., near the Cash, Storm Cloud, and Senator properties, the latter being operated by Phelps, Dodge & Co., in the 110-ft. adit a good grade of copper-gold-silver ore has been opened. On the Peacock claim, a shaft is 125 ft. deep, and a cross-cut has passed through 14 ft. of ore. Other promising developments have been made. The Arkansas & Arizona mine at Jerome is to sink its main shaft from 1400 to 2000 ft. A large orebody was opened at 1200 ft. A line is to be constructed from the shaft to connect with the railroad from the Clarkdale smelter to the

main tunnel of the United Verde mine, thus giving direct transport without rehandling. W. A. Clark, who expects the new smelter at Clarkdale to be ready by September 1, is erecting a model town there for his employees. He intends to run the place entirely on company account.

CALIFORNIA

BUTTE COUNTY

Two dredges of the Oroville Company recovered gold worth \$3634 during the week ended May 7.

ELDORADO COUNTY

New equipment at the Toadstool mine, in the Diamond district, has been tested. A good deal of ore is blocked out.

NEVADA COUNTY

A large flow of water was opened in the Delhi mine at Columbia Hill, and the mine is flooded. Extra pumps will be installed. The recent clean-up at the Golden Centre mill, Grass Valley, more than paid expenses. Rich ore is still being extracted from the Pennsylvania mine, and 20 stamps

MAP OF NEVADA COUNTY, CALIFORNIA.

are working full time. On May 11 the Grass Valley Miner's Union held its annual picnic, all mines and mills being shut down.

PLUMAS COUNTY

The Walker copper mine, in Grizzly valley, was recently examined by J. F. Cowan, of Salt Lake City. Some rich ore is showing, and the property is to be fully equipped.

SIERRA COUNTY

Another winze is being sunk in the Tightner mine at Alleghany. It is in 2000 ft. from the portal of the main adit and is 800 ft. below the apex of the vein, also 1300 ft. below the summit of the hill. This winze or shaft will prospect ground between the old Johnson shoot and the Red Star claim. There is fair activity near Gibsonville, now that the snow has disappeared. Twenty-eight men are working at the Miner's Home, a placer mine on Howland flat. Work at the North Fork mine, near Forest City, resulted in the Uncle Sam vein being picked up again.

COLORADO

BOULDER COUNTY

The mill of the Southern Illinois Mining Co. has made a satisfactory run. A flotation process, devised by Henry E. Woods, of Denver, is doing good work in recovering tellurides, which occur in this district. Curtis Brown is manager for the Company.

LAKE COUNTY (CLARK)

Mining is to be started again by claim owners in the Birds-eye, French Gulch, and Alicante districts. Ore opened in the past contains gold and silver. From the Tenderfoot, in South Evans gulch, a good tonnage of gold-silver-lead ore

is being extracted. Work in this and Big Evans gulch is quite active. The Walker adit is being driven into the Mosquito range; Little Ellen is producing gold ore; the St. Louis adit is being driven, and ore has been cut; the Ollie Reed is opening well; a large output is coming from the Dean shaft of the Forrest Rose; while lessees in other properties are busy on development and ore extraction. Rich gold ore has been opened in No. 5 adit of the Mt. Champion in Lackawanna gulch; a lower adit is to be driven. Eleven cars of lead and silver ore were shipped from the Hill Top mine last week to the Salida smelter. The bins are now full of ore.

MESA COUNTY

The Unawee copper district, 12 to 15 miles west of White-water on the D. & R. G. railway, is described by B. S. Butler in *Bulletin* 580-B of the U. S. Geological Survey. The area was examined in September 1913. The ore occurs in fissures that cut both igneous and sedimentary rocks, and the prevailing vein minerals are calcite, quartz, and a little fluorite, together with pyrite and chalcopyrite. Most of the ore contains a high percentage of primary sulphide, even in shallow workings. Considerable prospecting has been done, but most of the claims were idle at the time of this visit. The McKinley is opened to 600 ft. In the Nancy, a shoot was followed to 50 ft., and produced 21 cars of 16% ore. The Chance and Bell claims have also been developed.

MINERAL COUNTY

(Special Correspondence.)—A short visit to Creede shows that there is not much excitement there. The Del Monte, Amethyst, and Commodore mines are each shipping about 1000 tons of crude ore per month. The two concentrating mills, the Amethyst and the Humphreys, are both shut down, and probably will not start up until the price of lead goes up. (The fact that they are shut down will doubtless bring joy to the hearts of the fishermen.) The people there are hoping for a resumption of the tariff on lead. The fluor-spar mine at Wagon Wheel Gap has a good deal of high-grade material developed, but no market. The tariff is also blamed for this.

Creede, June 10.

SUMMIT COUNTY

No. 1 dredge of the Tonopah Placers Co., at Breckenridge, has been busy digging mud and sand out of an old pit, filled for several years. Some rich gravel is nearby, and the boat will have to cross a railway, so a new track will be built around the boat; then it will cut through and restore the original track. Leadville men are reopening the Gold Dust mine at Breckenridge.

THE SAN JUAN

The Camp Bird company, of Ouray, report for the quarter ended March 31 shows the following results:

| | |
|-------------------------|-----------|
| Ore treated, tons | 6,695 |
| Bullion sold | \$106,932 |
| Concentrate sold | 86,413 |

| | |
|---------------------|-----------|
| Total revenue | \$193,345 |
| Profit | 98,287 |

Mine development amounted to 855 ft., and 81,160 cu. ft. of stoping. Ore broken in stopes, at the end of the term, totaled 16,164 tons. While small shoots of ore were opened, on No. 6 and 8 levels, nothing of importance was disclosed.

Shipments of concentrate and crude ore from the Silver-ton district during May were as follows: Concentrate: Iowa Tiger, 12 cars; Gold King, 42; and Sunnyside, 21; a total of 75 cars. Crude ore: Arastra Leasing Co., 1; Gold Tunnel, 4; Slattery (Silver Lake), 7; Aspen, 3; Mayflower Leasing Co., 3; Primrose Leasing Co., 6; and Anti Periodic, 1; a total of 25 cars. The Tomboy, at Telluride, produced bullion worth \$40,000 and concentrate worth \$38,500 from 12,000 tons of ore in May. Net profits were \$31,200. At the Missoula copper

mine of the Snowstorm company, 55 men are employed. An ore-shoot 700 ft. long is said to have been opened. Ore is to be shipped from the Castle Rock, which contains copper and silver. About three miles above the Snowstorm mine are the Tucker Mining & Milling Co.'s silver and gold claims. A 900-ft. adit has been driven to cut the vein at a depth of 250 to 400 feet.

IDAHO

ELMORE COUNTY

Seventy-four miles from Boise, the Boise King Placer Mining Co. is operating on the middle fork of the Boise river. The Company has 740 acres of ground, the gravel averaging about 30 ft. depth, containing good gold content. An Evans elevator of 6000-yd. daily capacity is in operation. There is also a Ruble elevator and three giants, and nearly 20,000 yd. of material is moved per 24 hours. The Elmore Placer Mining Co. has a dredge at Featherville. There are other sluicing concerns in the district.

SHOSHONE COUNTY

Ore and concentrate shipments from Coeur d'Alene mines in May were as follows:

| Mines. | Tons. | Mines. | Tons. |
|-------------------------|-------|-----------------------|--------|
| Hercules | 7,000 | Success | 1,385 |
| Bunker Hill & Sullivan. | 5,500 | Gold Hunter | 1,020 |
| Morning (23 days).... | 4,500 | Ontario | 750 |
| Green Hill-Cleveland... | 3,300 | Marsh | 500 |
| Stewart | 3,500 | Snowstorm ... | 1,015 |
| Interstate-Callahan ... | 2,800 | National Copper | 300 |
| Hecla | 2,000 | Crown Point | 100 |
| Last Chance | 2,000 | Caledonia | 200 |
| Tamarack & Custer.... | 1,700 | Yankee Boy | 50 |
| Sierra Nevada | 1,200 | | |
| | | Total | 38,820 |

The Washington Water Power Co. has contracted through its agent, M. C. Osborn, with the Western, Snowshoe, Ray Jefferson, and Treasurer Vault companies to supply power for 50, 75, 75, and 75-hp. motors and air-compressors respectively. The Stewart mine is being examined by an engineer who was accompanied by N. J. Miller, of New York City, who represents the Stewart Mining Company Stockholders' Protective Association. A fight for control of the property will be held at the next annual meeting. On the east drift of the Sunset, at 400 ft., 16 ft. of galena with some lead and zinc ore has been opened. This is a W. A. Clark property. Sinking is to be resumed at the Success. At what is known as the 1000-ft. level, or 300 ft. below the main adit, 35 ft. of 30% zinc ore is showing. The magnetic separator in the mill is doing good work on the zinc concentrate. A Callow flotation plant is to be installed.

MICHIGAN

HOUGHTON COUNTY

At the Mohawk, 750 men are employed, which is more than at any time in its history. The stamp-mill at Gay is working full time. Good copper 'rock' is being opened on the lower levels at No. 2 shaft. At the Winona, 450 men are employed, which is 200 more than before the strike.

MONTANA

SILVERBOW COUNTY

The Butte & London mine was dewatered to 800 ft. last week. At this point is a large station with an expensive pump, which has been there since the mine shut down, five years ago. It was then painted, greased, and packed, and was found to be in splendid condition after its long immersion in water. It will be changed from steam to electric power, and used again. During May the Butte & Superior mill treated 33,510 tons of ore, yielding 10,010 tons of concentrate assaying 33.59%

zinc. The recovery was 88.38%, and total zinc produced 10,729,398 pounds.

On June 13 the Butte Miners' Union held its thirty-fourth anniversary, which resulted in serious riots. Over 2000 men refused to recognize the union, and under leadership of I. W. W. members attacked the parade being held, also did considerable damage in the union hall. A new union will probably be formed. The trouble had its origin over the dissatisfaction of the miners with heavy special assessments levied against them by the officers of the Western Federation of Miners and the local officials as benefits for the Michigan copper mine strikers. Some of the miners were said to be paying as high as \$8 to \$10 per month in assessments. Although the strike there has been called off, the assessments continued. The climax came on June 12, when the men employed at the Speculator mine of the North Butte company refused to exhibit their union cards to the six walking delegates of the union sent there to inspect them. The union officials informed the mine management that the men would not be allowed to go to work. The men marched down from Butte hill and that night called out the night shift. Men from the Butte & Superior mines also joined the movement. Work has since been resumed at the mines.

MISSOURI

JASPER COUNTY

Lessees on the St. Paul Mining Co.'s land at Spring City are opening good lead and calamine at 150 ft., while east of the Hash mine the Black Hawk is showing lead and calamine at 15 ft. Hand jigs are used to clean the ore. After being idle for nine months, the 150-ton mill at Klondyke is to be restarted. Zincblende was cut at 115 ft. in the New England mine nearby. Eighteen per cent ore is being milled from the old Marlon B. mine.

NEVADA

ESMERALDA COUNTY

The annual meeting of the Jumbo Extension Mining Co. will be held at Phoenix, Arizona, on July 13. Net ore returns for the past five months were \$118,000, and net profits \$60,000. The Velvet claim, recently purchased, is showing twice as much ore as the purchase price. A side-line agreement, instead of the apex agreement, has been made with the Goldfield Consolidated company. The estimated net return for May was \$24,000. Development in the Florence continues to be satisfactory. Drilling is under way at 810 ft. in the Oro mine.

MINERAL COUNTY

Another option which expired on June 15, was given the Goldfield Consolidated on the Aurora Consolidated property, according to W. Lester Mangum, the general manager of the latter. The price was \$927,000. Albert Burch, of the Goldfield mine, has been at Aurora in connection with the business. The new mill at Aurora, constructed by Kirk & Leavell, of Salt Lake City is nearly completed.

NYE COUNTY

Ore production of Tonopah mines last week was 11,455 tons, valued at \$295,395. May yields were as follows: Belmont, 15,561 tons, yielding 343,740 oz. bullion, with a profit of \$152,411; Jim Butler, 3955 tons, with a profit of \$42,924; Tonopah Mining, 12,111 tons, yielding 218,525 oz. silver and 103 tons of concentrate worth \$35,155, the profit being \$99,695.

WASHINGTON COUNTY

A new gold discovery is reported about 10 miles from Reno.

WHITE PINE COUNTY

Accidents at the Nevada Consolidated properties in May were as follows: Veteran mine, five trivial disabling injuries; Copper Flat, 11 disablements; concentrating plant, 800 men employed, one man off for four shifts; smelter, 600 to 700 employed three small injuries; the total accidents being

20, involving a loss to the men of 90 days in all, which is a good record.

NEW MEXICO

The production of coal in New Mexico in 1913 was 3,708,806 short tons, with a value at the mines of \$5,401,260, according to E. W. Parker, of the U. S. Geological Survey, who compiled the figures in cooperation with the State Geological Survey. In 1913, as in 1912, New Mexico beat all previous records in the production of coal. The output in 1912 was 3,536,824 tons, valued at \$5,036,824. The average price in 1913 was \$1.33 per ton. Colfax county produced 2,749,765 short tons out of the total of 3,708,806 tons for the state. The number of men employed in the coal mines increased from 3928 in 1912 to 4329 in 1913. The average production per man decreased from 900 tons in 1912 to 857 tons in 1913. This decrease was not due to any falling off in efficiency, but was one of the minor effects of an appalling disaster which occurred at mine No. 2 of the Stag Cañon Fuel Co., at Dawson, in October 1913. This accident, one of the most disastrous of the year in coal mining, and the worst in the history of the state, caused the death of 261 persons. It occurred in one of the mines of a Company which had spared no expense, and had taken every precaution human intelligence could suggest to reduce the hazard of coal-mining operations. The other fatalities reported to the U. S. Bureau of Mines outside of the explosion at Dawson were 11, making a total of 272. Only one instance of labor trouble was reported in 1913, and in this eight men were on strike for 130 days.

OREGON

JACKSON COUNTY

The Northern California-Southern Oregon Mining Congress will meet at Ashland on July 9 and 10. L. J. Luce, of Etna Mills, Siskiyou county, California, will preside. Following is the official program: First day, reception at Commercial Club rooms; address of welcome by the mayor, Mr. Johnson; response, F. J. Newman, of Medford, S. J. Taylor, of Yreka; president's address, L. J. Luce; S. B. Edwards, of Grants Pass, 'Placer Mining in Southern Oregon'; H. N. Lawrie, of Portland, 'Mining Industries of the State'; and R. A. Watson, corporation commissioner, 'Blue Sky Law, Relation to Mining Industry.' On the second day the following papers are to be read: A. L. Lamb, of Ashland, 'Mining in Jackson County'; J. Mangum, 'Mining in Josephine County'; Henry M. Parks, 'Mineral Resources of Oregon'; address by F. McN. Hamilton, state mineralogist of California; C. B. Watson, of Ashland, 'Clay and Kaolin and Their Possibilities,' 'Iron and Copper, Their Relation to Commercial Industries'; E. P. Hopson, 'Irrigation and Reclamation'; and an address by C. L. Probsted, 'Mineral Resources of Siskiyou County.'

UTAH

SALT LAKE COUNTY

At the western foot of the Wasatch range, between the mouths of Little and Big Cottonwood creeks, and 15 miles southeast of Salt Lake City, the Wasatch-Utah Mining Co. has a large low-grade property, the ore of which can be treated at a net profit of \$1 per ton. A 5-stamp mill has been used to test the ore, and with cyaniding a good recovery can be made. A mill of 500-ton daily capacity is proposed. The ore is soft, and mining costs will be low. A. W. Nieman, of Salt Lake City, is president.

SUMMIT COUNTY

Remodeling of the old Grasselli zinc mill at Park City is well under way, and it should be ready for work by July 15. The capacity is to be 50 tons per day, most of which will come from the American Flag mine. During May the Thompson-Quincy mine produced 35 mine-cars of first class and 70 cars of mill ore.

WASHINGTON

'The Mining Advance into the Inland Empire,' being a comparative study of the beginnings of the mining industry in Idaho and Montana, eastern Washington, and Oregon, and the southern interior of British Columbia, and of institutions and laws based upon that industry, is the subject of a thesis submitted for the degree of doctor of philosophy at the University of Wisconsin, by William J. Trimble. The publication is *Bulletin* 638, history series, containing 254 pages, and is sold for 40 cents per copy. It includes an introduction on the region and the movement, history from 1855 to 1870 in each state, economic and social aspects of the mining advance, together with a discourse on the law and government.

CANADA

BRITISH COLUMBIA

The Consolidated Mining & Smelting Co. has installed a pulmotor and other up-to-date rescue apparatus in its mines at Rossland. Classes will shortly be arranged for instructing the miners in the use of the machine and apparatus. Large numbers are taking the first-aid classes organized by Dudley Michell, representing the Department of Mines.

The Le Roi No. 2 company will probably acquire the Giant-California claims.

ONTARIO

During May the Nipissing refinery shipped 523,320 fine ounces of silver. Prospecting by hydraulicking is in progress near shaft 86. The cross-cut at 900 ft. depth is expected to soon cut the main vein, the distance being estimated at 255 ft. Other development was satisfactory.

The McIntyre mill treated 4480 tons of \$11.10 ore in May, yielding \$47,180. A station is being cut at 500 ft. at No. 4 shaft. Vein No. 6 was cut in the Tough-Oakes last week. It is 14 in. wide and of high grade, being parallel to No. 3 vein. A 100-ton mill is proposed next fall.

The recent statement of the McIntyre company for the year ended December 31, 1913, shows that for the twelve months the average value of the ore milled was \$5.18, while the cost was \$6.60. This report is very discouraging, but since that time better and more economical mining methods and more favorable underground development has placed the Company in a better position. From January 1 to March 31, 1914, the mill treated 11,190 tons averaging \$9.83, while during March over 4000 tons was milled, the average of which was \$12.68. In April the mill treated 4200 tons averaging \$10.70, and shipped bullion to the value of \$46,100. The capacity of the mill is being increased to 300 tons per day. The recovery of this Company from its former unfortunate position is an encouraging feature.

YUKON

With the exception of No. 1, at the mouth of Bonanza creek, and No. 6 on Gold Run, the Yukon Gold Co.'s dredges were at work on May 22. No. 3 and 8 started on May 12, No. 5 and 9 on May 13, and No. 2 and 4 on May 14. No. 1 and 6 were expected to start early in June. Of those operating, one is on Eldorado, one on upper Bonanza, one on 41 Hunker, and three on lower Bonanza. The hydraulic plants are also busy, the Fox gulch giants starting on May 8, and at Lovett gulch on the following day. The Twelve-mile power-plant started on May 9, this power being used on the dredges.

Canadian Klondyke dredges recovered 3192 oz. gold during the week ended May 23.

An adit has been driven 506 ft. into a hill on Hale creek, a few miles below Dawson, by A. T. Heydon, who expects soon to cut a buried gravel channel. He thinks a great deal of good gravel will be found.

Shipments of copper ore are being made from the Atlas company's Pueblo mine, at Whitehorse, to Tacoma. There

are 160 miners and 40 others employed on the property. Ore is coming from the 200 and 400-ft. levels. The Eureka Creek district is active, and a number of gravel dumps are being

STRIPPING OPERATIONS OF THE YUKON GOLD CO., CLAIM 88 BELOW BONANZA, SHOWING CREEK IN CENTRE AND CROSS-DITCHES IN 'MUCK.'

washed. The business portion of the town of Atlin was reported to have been destroyed during the first week in May.

CHILE

The Braden mill during May treated 70,477 tons of ore. The grade of this ore was 2.11%, and the recovery 75.36%. The production of blister copper for the month was 2,480,000 lb. While more than 200,000 lb. below that of April, it is the second largest monthly production from the mine. Development in progress disclosed some good ore. One of the cross-cuts on the No. 1 Teniente level advanced in ore, bringing the average for the 292 ft., so far driven, to 3.44%. In a raise above this level, which advanced 150 ft., the total distance of 630 ft. averages 3.32% copper. The extraction obtained of 75.36% for the month showed a marked improvement over that of April, when the recovery was 69.9%. The tonnage reported for May was all handled in the new mill, as the old mill was closed, the equipment now having been moved to the new plant. In April the tonnage handled in the new mill was 77,000, and in the old mill 5700, a total of 82,700 tons. The concentrator at Braden now has a capacity of about 3500 tons per day, or around 100,000 tons per month. The enlargement, however, of this plant is under way and its capacity will be increased to about 4500 tons.

COLOMBIA

The Pato dredge recovered gold worth \$10,350 from 54,250 cu. yd. during the fortnight ended May 19.

KOREA

A gold refinery is to be established at Pyongyang by Fusano Hisahara, a Japanese capitalist. With their present crude methods of refining gold, Japanese and Korean miners waste a considerable quantity of the metal. At the Hidachi mine a similar plant is working satisfactorily.

PHILIPPINE ISLANDS

A new 5-ft. dredge of the Malaguit Dredging Co. started work in the Paracale district in April. J. A. Bruce is in charge. The governor-general of the territory, Burton Harrison, recently gave a 'straight talk' to the business community of Manila, which has considerably cleared the air and promoted a distinctly better feeling in business circles, according to *The Far Eastern Review*.

Personal

W. W. MEIN is in San Francisco.
SIDNEY JENNINGS has gone to Europe.
H. W. MACFARREN has gone to Plumas county.
C. R. WILEY is at the Barstow property at Ouray.
W. H. STORMS is studying the Mt. Lassen eruption.
WILLIS T. BURNS was in New York City last week.
J. W. RICHARDS has gone to Norway for the summer.
R. M. RAYMOND is staying in New York City for a time.
H. V. WINCHELL is expected in New York City at the end of this week.

C. W. PURINGTON has left St. Petersburg for the Lena district of Siberia.

H. G. S. NOBLE has been elected president of the New York Stock Exchange.

JINTARO KOJIMA, of the Furukawa Copper Co., is visiting Western copper mines.

J. F. KEMP is at Lake George, New York, and will go to Cuba later in the summer.

FREDERICK CLOSE passed through San Francisco last week, returning from Juneau to London.

HENNER JENNINGS is in New York City and expects to come to California later in the summer.

G. M. TRENT, manager of the L. C. Trent Engineering Co., of Los Angeles, is in San Francisco.

F. L. LOWELL, of the State Mining Bureau, is examining mines in Mariposa county, California.

W. F. DEANER has resigned as manager for the Original Amador company, at Amador City, California.

W. DEL. BENEDICT has returned to New York after an absence of ten weeks in California and Washington.

WILLIAM MOTHERWELL, of Australia, is at Humboldt, Arizona, with the Consolidated Arizona Smelting Company.

MORTON WEBBER has been examining a low-grade gold property in the vicinity of Pioche, Nevada, for New York interests.

G. D. LOUDERBACK will sail for China on June 28 to take charge of a geological survey party for the Standard Oil Company.

HENRY JONES, a well known manufacturer of Tasmania, and largely interested in tin properties in the Malay Peninsula, is in San Francisco.

J. B. TYRRELL, Canadian representative of the Anglo-French Exploration Co. of London, is investigating the mining conditions of British Columbia.

GEORGE E. FARISH has just returned to New York from the San Juan district in Colorado, where he has been engaged in examination work since February.

N. DICKERMAN, general manager for the Pato Mines (Colombia), Ltd., has arrived in New York City from London and will be in San Francisco the last of June.

N. W. SWITZER has been promoted from engineer at the Phoenix, B. C., mines of the Granby Con. M. S. & P. Co. to superintendent of the Hadley, Alaska, mines of the same Company.

R. S. RAINSFORD has resigned as general manager for the Argonaut Mining Co. at Jackson, California. He will be succeeded by N. KELSEY, who has been assistant superintendent of the mine.

CHARLES A. DINSMORE, of the *El Paso Mining Journal*, appeared May 19. Any information as to his whereabouts will be welcomed by Mrs. Dinsmore, whose address is: First State Bank, Artesia, New Mexico.

PERCY A. SEIBERT, manager for the Andes Tin Co., Bolivia, is on holiday in Paris, where his address is 53 bis rue de Villiers, Neuilly-sur-Seine. In his absence from La Paz, JOSEPH A. LESTER is in charge of the affairs of the company.

D. C. JACKLING left about June 15 for Alaska on an inspection trip of the Alaska Gold Mines Co. property, which he expects will take a great deal of his attention this summer. Mr. Jackling will be accompanied on the trip by a number of friends and business associates, among whom are L. S. CATES, general manager for the Ray Consolidated Copper Co.; HOWARD FRITCH, general manager for the Kansas City Structural Steel Co.; GEORGE WOOLSEY, of Tripp & Co., bankers, of New York; M. B. MCKELVIE, junior partner of Hayden, Stone & Co., of Boston; J. FRANK JUDGE, of Salt Lake City; N. B. POLL, editor of the *Boston News Bureau*, of Boston; H. S. ALEXANDER, president of the Alaska-Pacific Navigation Co.; GEORGE O. BRADLEY, chief mechanical engineer for the Utah Copper Co.; J. G. JANNEY, manager of the mills of the Alaska Gold Mines Co. and the Utah Copper Co.; and CHARLES W. STIMPSON, of the Stimpson Equipment Co. of Salt Lake City. The party will return to Seattle about July 3.

The U. S. CIVIL SERVICE COMMISSION announces an open competitive examination for assistant mining engineer on July 13, 1914, for men only. From the register of eligibles resulting from this examination, certification will be made to fill vacancies in this position in the Bureau of Mines, for service in the field, in relation to coal mining or metal mining, at salaries ranging from \$1800 to \$2400 per year.

MICHIGAN COLLEGE OF MINES, at Houghton, started its practice work in metallurgy and ore dressing on June 9. Ore to be treated this year is five tons from the Dome mine at Porcupine, Ontario. A week will be spent watching the operation of six mills in the district; also two weeks in the plant of the Michigan Smelting Company.

The AUSTRALASIAN INSTITUTE OF MINING ENGINEERS held its 1914 meeting at Melbourne, Victoria, on May 21 to 30. A three days' trip was made to the gold mines of Walthalla and the government coal mines at Wonthaggi.

The Metal Markets

LOCAL METAL PRICES

June 18.

| | | |
|--|-------|-----------|
| Antimony | 9 | — 9 3/4c |
| Electrolytic copper | 15 | — 15 1/4c |
| Pig Lead | 4.15 | — 5.10 |
| Quicksilver (flask) | | \$38.50 |
| Tin | 39 | — 40 1/2c |
| Spelter | 6 1/2 | — 6 3/4c |
| Zinc dust, 100 kg. zinc-lined cases, 7 1/2 to 8c. per pound. | | |

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, June 18.—All metal markets are dull and weak. Copper and spelter are a trifle lower than last week, and lead is the same price. It is feared that labor troubles at Butte may result as in Michigan last year. News from Mexico affected American Smelting & Refining shares. Tin is firm at 30.20 to 30.50c. spot; and antimony is dull at 7.25 to 7.37 1/2c. The St. Louis lead and spelter markets are exceedingly dull at 3.80 to 3.82 1/2c. and 4.92 1/2c. respectively. In London copper is firm at £61 16s.3d.; lead, £19 17s.6d.; spelter, £21 5s.; tin £137 10s. to £139; and bar silver quiet at 25.94d. per ounce.

SILVER

Below are given the average New York quotations in cents per ounce, of fine silver.

| Date. | Average week ending | | |
|-------------------|---------------------|------------------|-------|
| June 11 | 56.87 | May 6 | 59.14 |
| " 12 | 56.25 | " 13 | 58.73 |
| " 13 | 56.75 | " 20 | 58.31 |
| " 14 Sunday | | " 27 | 57.12 |
| " 15 | 56.50 | June 3 | 56.52 |
| " 16 | 56.50 | " 10 | 56.48 |
| " 17 | 56.50 | " 17 | 56.56 |
| Monthly averages. | | | |
| Jan. 1913. | 57.58 | July 1913. | 58.70 |
| Feb. 1914. | 57.53 | Aug. 1914. | 59.32 |
| Mch. 1913. | 58.01 | Sept. 1913. | 60.53 |
| Apr. 1914. | 58.52 | Oct. 1913. | 60.88 |
| May 1913. | 58.21 | Nov. 1913. | 58.76 |
| June 1913. | 59.03 | Dec. 1913. | 57.73 |

The rally recorded last week proved to be short lived, according to Samuel Montague & Co., writing on June 4. So little animation was felt that prices shed fractions each day, until yesterday 25 1/4d. was fixed for cash and 25 1/2d. for two months delivery. It is considerably over two years since such low prices have been touched, not since January 17, 1912, when 25.7d. and 25 1/4d. were fixed for the respective deliveries. The fact is the more remarkable, as business frequently has been on an extremely small scale. The only apparent cause for the low level of prices now ruling is an exceptional reluctance of buyers to support the market. It will be observed that the shipment from San Francisco to China, which was £120,000, is unusually large. Sales aggregating to so considerable a sum as comprised in this shipment contributed to make that quarter rather inactive so far as the London market was concerned. It is possible that the imminence of the monsoon deters the Indian Bazaars from purchasing until it can be reasonably anticipated that favorable climatic conditions are assured. Today buying orders were received from China, and as sellers were disposed to hold off, a sharp rise took place of 0.2d. in the price for both deliveries. An Indian currency return, cabled on June 4, shows an increase in the note issue of 110 lacs, and in the holding of silver rupees of 140 lacs. The holding of gold in India has decreased by 30 lacs (1 lac = \$32,000). The stock in Bombay has decreased from £470,000 to £405,000. The off-take is unchanged at 100 bars per day. The holdings in Shanghai by banks and others consist of £5,770,000 in sycee or currency, a decrease of £70,000. The holding of bars is about the same, namely, £35,000. (Sycee is a shoe-shaped bar weighing from 50 to 60 ounces.)

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

| Week ending | June 4 | 1913 | 1914 |
|-------------------|--------|------------------|-------|
| May 21 | 39.00 | " 11 | 38.50 |
| " 28 | 39.00 | " 18 | 38.50 |
| Monthly averages. | | | |
| Jan. 1913. | 39.37 | July 1913. | 41.00 |
| Feb. 1914. | 41.00 | Aug. 1913. | 40.50 |
| Mch. 1913. | 40.20 | Sept. 1913. | 39.70 |
| Apr. 1914. | 41.00 | Oct. 1913. | 39.37 |
| May 1913. | 40.25 | Nov. 1913. | 39.40 |
| June 1914. | 41.00 | Dec. 1913. | 40.00 |

COPPER

Quotations on copper as published in this column represent average wholesale transactions on the New York market and refer to electrolytic copper. Lake copper commands normally 1-5 to 1-4c. per lb. more. Prices are in cents per pound.

| Date. | Average week ending | | |
|-------------------|---------------------|------------------|-------|
| June 11 | 13.65 | May 6 | 14.02 |
| " 12 | 13.65 | " 13 | 13.93 |
| " 13 | 13.65 | " 20 | 14.00 |
| " 14 Sunday | | " 27 | 13.98 |

| " 16 | 13.65 | " 10 | 13.75 |
| " 17 | 13.65 | " 17 | 13.65 |
| Monthly averages. | | | |
| Jan. 1913. | 16.54 | July 1913. | 14.21 |
| Feb. 1914. | 14.93 | Aug. 1913. | 15.42 |
| Mch. 1913. | 14.72 | Sept. 1913. | 16.23 |
| Apr. 1914. | 15.22 | Oct. 1913. | 16.31 |
| May 1913. | 15.42 | Nov. 1913. | 15.08 |
| June 1914. | 14.71 | Dec. 1913. | 14.25 |

Copper production of the Wallaroo and Moonta mines, South Australia, to the end of 1913 was as follows: ore mines, 10,200,000 tons; average copper content, 3%; fine copper yield, 283,682 tons; dividends, \$10,704,000.

LEAD

Lead is quoted in cents per pound or dollars per hundred pounds, New York delivery.

| Date. | Average week ending | | |
|-------------------|---------------------|------------------|------|
| June 11 | 3.90 | May 6 | 3.90 |
| " 12 | 3.90 | " 13 | 3.90 |
| " 13 | 3.90 | " 20 | 3.90 |
| " 14 Sunday | | " 27 | 3.90 |
| " 15 | 3.90 | June 3 | 3.90 |
| " 16 | 3.90 | " 10 | 3.90 |
| " 17 | 3.90 | " 17 | 3.90 |
| Monthly averages. | | | |
| Jan. 1913. | 4.28 | July 1913. | 4.35 |
| Feb. 1914. | 4.33 | Aug. 1913. | 4.60 |
| Mch. 1913. | 4.32 | Sept. 1913. | 4.70 |
| Apr. 1914. | 4.36 | Oct. 1913. | 4.37 |
| May 1913. | 4.34 | Nov. 1913. | 4.16 |
| June 1914. | 4.33 | Dec. 1913. | 4.02 |

Metal production of the Broken Hill Proprietary Co., New South Wales, during the four weeks ended May 7 was as follows: Silver from Company ore, 127,966 oz., and from custom ore, 187,842 oz.; lead from Company ore, 1748 tons, and from custom ore, 4505 tons; antimonial lead, 27 tons; zinc concentrate, 5550 tons, containing 71,023 oz. silver, 354 tons lead, and 2591 tons of zinc. The output was low on account of holidays.

ZINC

Zinc is quoted as spelter, standard Western brands, St. Louis delivery, in cents per pound.

| Date. | Average week ending | | |
|-------------------|---------------------|------------------|------|
| June 11 | 4.85 | May 6 | 4.87 |
| " 12 | 4.85 | " 13 | 4.90 |
| " 13 | 4.85 | " 20 | 4.95 |
| " 14 Sunday | | " 27 | 4.93 |
| " 15 | 4.85 | June 3 | 4.90 |

| June 1914. | 5.00 | Dec. 1913. | 5.07 |

TIN

New York prices control in the American market for tin, since the metal is almost entirely imported. San Francisco quotations average about 5c. per lb. higher. Below are given average monthly New York quotations, in cents per pound:

| Month | 1913 | 1914 | 1913 | 1914 |
|-----------|-------|-------|------------|-------|
| Jan. | 59.45 | 37.85 | July | 40.70 |

Mineral Production of Japan

The Department of Agriculture and Commerce has recently published the result of its investigations into the conditions of the mining industry of this country. The yield of the principal minerals during 1913 was valued at 146,657,813 yen, the highest output in recent years. Compared with the preceding year, these figures are an increase by 10%, that is, 16,416,478 yen. Eliminating silver, which had a decrease of 170,000 yen as compared with the preceding year, all other principal minerals have increased, the gain being heaviest in coal. Details are as follows:

| | Yen.* |
|-----------------------------------|--------------------|
| Gold..... | 7,281,411 |
| Silver..... | 5,708,975 |
| Copper..... | 41,738,339 |
| Iron..... | 3,418,224 |
| Coal..... | 70,956,121 |
| Kerosene oil..... | 12,498,506 |
| Sulphur..... | 1,556,826 |
| Other miscellaneous minerals..... | 3,499,412 |
| Total..... | 146,657,814 |

*One yen = about 50 cents U. S. coinage.

MONEY IN CIRCULATION in the United States on June 1, as estimated by the Treasury Department, totaled \$3,480,074,312, made up as follows: gold coin, \$615,431,580; gold certificates, \$1,105,753,619; standard silver dollars, \$70,680,082; silver certificates, \$466,402,217; subsidiary silver, \$159,629,313; treasury notes, 1890, \$2,450,805; United States notes, \$339,992,091; and national bank notes, \$719,734,605. The circulation per capita was \$35.19.

THE U. S. ASSAY OFFICE at New York transacted the following business in May: gold bars paid on deposit, \$259,397; gold bars exchanged for gold coin (domestic), \$2,519,325; exports to Canada, \$32,425; and exports to Europe, \$5,941,797. Transactions for the current year total \$36,465,254, against \$34,283,992 for the whole of 1913.

PHOSPHATE ROCK reserves of the United States are estimated as 10,519,875,000 tons, of which 10,000,000,000 tons is in Utah, Idaho, Wyoming, and Montana; 374,300,000 tons in Florida; 115,075,000 tons in Tennessee; 10,000,000 tons in South Carolina; 20,000,000 tons in Arkansas; and 500,000 tons in Kentucky.

PIG-IRON PRODUCTION of the United States in May totaled 2,092,686 tons, an average of 67,506 tons per day. This was 8000 tons per day less than in April. There were 197 furnaces active on June 1.

GOLD AND SILVER EXPORTS from New York to June 6 amounted to \$37,278,299 and \$17,912,660 respectively, against \$59,792,290 and \$23,151,073 for the same time last year.

UNDERGROUND ELECTRIC RAILWAYS of London carried approximately 1,100,000,000 passengers during the past financial year. Gross earnings were \$31,932,300.

Company Reports

NORTH LAKE MINING COMPANY

This Michigan copper company has not yet reached the producing stage. Shaft-sinking was in progress in 1913, and had reached a depth of 345 ft. when the strike caused a shut-down. A cross-cut is being driven on the 300-ft. level and has advanced 112 ft. The balance sheet of the Company for December, 31, 1913, shows cash assets of \$22,783 and total assets of \$904,649. During 1913, \$30,000 was expended on development work.

CONSOLIDATED COPPERMINES COMPANY

The Consolidated Coppermines Co. has issued a report covering the period from May 20, 1913, to April 30, 1914. The report shows that the Company, which was incorporated May 20, 1913, owns 1151 acres in the Ely district besides 2565 acres of ranch land and valuable water rights. Ore reserves are as follows:

| | Giroux mine. | Old Copper-mines. |
|--------------------------------|--------------|-------------------|
| Fully developed, tons | 14,199,180 | |
| Copper content, per cent..... | 1.219 | |
| Partly developed, tons | 6,456,872 | 968,184 |
| Copper content, per cent | 1.041 | 1.01 |

For the purpose of proving tonnages and grade of the ore, several drills were put to work. The holes so far put down have shown a close check on previous work. Seven holes were also drilled west of the Old Glory territory, with the result that the concentrating ore there was shown to be a continuation of the so-called Morris deposit. Heretofore it was supposed that these were distinct orebodies. In addition to the churn-drilling on the Giroux, underground mining was conducted at the Coppermines property, and the result of both drilling and underground work was satisfactory. No work was done on the Ely Central, Butte & Ely, or the Chainman properties. In the Morris Hill portion of the Giroux, six drill-holes have been put down below the 165-ft. level, the deepest level in the mine, with the result that a large additional tonnage of high-grade concentrating ore has been developed and partly developed. In calculating tonnages, no allowance has been made for the direct-smelting ores known to exist in the Old Glory, Taylor, Giroux, and Alpha shafts. The drilling which was carried on is said to have blocked out an additional tonnage of several million tons of ore under 1% copper, which can be mined by steam-shovel at a low mining cost, and most of which could be leached or otherwise treated at a profit. These ores will be handled in connection with the mining of the higher grade concentrating ores. During the period from June 1 to April 30, 170,298 tons was mined and shipped from the Giroux, producing 3,041,678 lb. of copper. The profit after expenditure was \$5814. In addition there was charged to drilling, general expense, and miscellaneous, the sum of \$178,944. The general manager, Mr. Gray, advises the erection of a small experimental plant in the old Giroux concentrator to determine the best treatment for the ores. Total receipts of the Company were \$247,352. Expenses were \$226,152, leaving a balance of \$21,200.

HOME MINES, LIMITED

The report of this Porcupine, Ontario, company covers the year ended March 31, 1914, and is complete in every detail. Development totaled 6892 ft., including shaft-sinking, and cost \$1.11 per ton milled. Ore reserves above the 100-ft. level are estimated at 512,600 tons averaging \$4.81 per ton. In addition to this tonnage of fully developed ore, work in the vicinity of No. 2 shaft has shown an additional tonnage,

which is partly developed, amounting to 2,000,000 tons and averaging \$3.50 per ton. Mining now extends along the strike of the orebody for 1250 ft. Practically all work during the year was done at No. 2 shaft in opening the No. 3, 4, and 5 levels, particularly No. 3, where a large orebody, equivalent to a horizontal area of 100,000 sq. ft., was proved. This was defined by 859 ft. of drifts and 969 ft. of cross-cutting, the sampling value being \$3.49 per ton. Only a limited amount of development was done on No. 4 and 5 levels, but further areas of ore have been exposed. On No. 4, 539 ft. of driving showed an area of 29,480 sq. ft., averaging \$4.03 per ton; and on No. 5, 644 ft. of work disclosed 37,000 sq. ft. of ore which sampled \$4.94 per ton. A much greater amount of work, however, will be necessary on No. 4 and 5 levels before it will be safe to estimate the probable size or value of the orebody. In the vicinity of No. 4 shaft, six diamond-drill holes were put down within an area of 15,000 sq. ft., and results indicate a considerable tonnage of profitable ore which will be developed from the 100-ft. level.

Records for the year show that an average of 4.203 tons of ore was produced per man per shift for all underground employees, and 1.73 tons per man per shift for all employees on the property. The stoping record shows that 43.7 tons was broken per machine shift with the large piston drills, and 61.01 tons per machine shift for the pluggers working in the open pits.

The mill ran 93.52% of the possible running time and treated an average of 398 tons of ore per day, making a

HOME MILL, PORCUPINE, ONTARIO.

recovery of 94.5%. The average stamp-duty was 10.6 tons per 24 hours. Of the total value recovered, 60.7% was by amalgamation, and 39.3% by cyanidation. The total ore treated was 145,305 tons, yielding \$1,204,598, equal to \$8.29 per ton. The total expenditure on operating development, plant, etc., was \$919,512. Costs were as follows: Mining, 68c.; hoisting, 7c.; crushing and conveying to mill, 25c.; stamping, tube-milling, and amalgamation, 86c.; thickening, cyaniding, and precipitating, 50c.; refining, 8c.; and general, 64c.; a total of \$3.08 per ton. This cost was \$1.49 lower than the previous year. The consulting engineer, W. W. Mein, states that working costs will be further reduced, and that when the enlarged plant is in operation they should be less than \$2.50 per ton. The mill's capacity is being increased to 28,000 tons per month, and this construction cost \$303,999. Cash on hand at the end of the term was \$168,749, and the surplus was \$486,520.

The Company possesses a large deposit of low-grade ore which should be worked by a policy of non-selective mining, and which gives assurance of a profitable life on the basis of the new treatment capacity, according to Mr. Mein. The advisability of further increasing the capacity of the mill will depend upon the results of further development from the lower levels of No. 2 shaft, and upon the establishment of low operating costs.

Production Statistics

THE FOLLOWING DATA, COVERING THE YEAR 1913, IS FROM THE UNITED STATES GEOLOGICAL SURVEY.

SLATE

Slate production of the United States amounted to 1,113,944 squares of roofing material averaging \$4 per square; 6,312,011 sq. ft. of mill stock, averaging 19.5c. per sq. ft.; and other products worth \$480,576, the total value being \$6,175,476. The other products include 6,174,526 school slates, and 3,504,162 sq. ft. of blackboard material. Pennsylvania and Vermont were the chief producing states. Practically no slate is imported, while exports amounted to \$226,413.

COAL MINING IN ALABAMA

The production of coal in Alabama in 1913 was 17,678,522 short tons, valued at the mines at \$23,083,724, according to figures compiled by E. W. Parker, in co-operation with the Alabama Geological Survey. The increase in coal production in Alabama in 1913 compared with 1912 was 1,577,922 short tons in quantity and \$2,254,472 in value. The number of men employed in 1913 was 24,552, against 22,613 in 1912. The total time lost by strikes in 1913 was 27,041 days, 1048 men being idle for an average of 26 days. There were 124 men killed in the coal-mining operations of Alabama in 1913.

APPALACHIAN OIL PRODUCTION

During 1913 this oilfield, embracing New York, Pennsylvania, West Virginia, southeastern Ohio, and Kentucky, showed a slight decline, 1.72%, in the production of petroleum, falling from 26,338,516 in 1912 to 25,885,640 bbl. in 1913, a decrease of 452,876 bbl. The value, amounting to \$63,619,677 in 1913, was, on the contrary, increased by 48.58%, about the same proportional increase as was shown in 1912 over the previous year. The largest amount, 2,307,422 bbl. was produced in April; the smallest amount, 1,963,460 bbl., in February. The average price per barrel increased from \$1.63 to \$2.46.

Production by states was as follows:

| State. | 1912. Barrels. | 1913. Barrels. |
|-----------------------------|-------------------|-------------------|
| New York | 874,128 | 902,211 |
| Pennsylvania | 7,837,948 | 7,927,137 |
| West Virginia | 12,128,962 | 11,567,299 |
| Southeastern Ohio | 5,013,110 | 4,964,425 |
| Kentucky | 484,368 | 524,568 |
| Total | 26,338,516 | 25,885,640 |

ANTHRACITE PRODUCTION

The production of anthracite again broke the record in 1913, exceeding the highest previous output by nearly 1,000,000 tons, according to figures compiled by E. W. Parker, coal statistician of the Survey. Including the coal recovered from old culm banks, and a small quantity dredged from Susquehanna river, the production of anthracite for the year was 81,718,680 long tons, valued at \$195,181,127, compared with 75,322,855 tons, valued at \$177,622,626 for 1912. The previous highest record was 80,771,488 long tons, in 1910. Anthracite miners and operators are now working under an agreement extending over a period of four years from April 1, 1912; there were consequently no serious interruptions to mining operations by labor troubles in 1913, and industrial peace is assured in the anthracite region until 1916. Another record in addition to that of tonnage was established in the anthracite region in 1913. The average working time for men, 257 days, exceeded anything in the history of the industry, the nearest approach being in 1911, when an average of 246 working days was recorded. In 1912 the average was 231 working days. The average number of men employed in

1913 was 175,745. Reports to the U. S. Bureau of Mines show that there were 618 fatal accidents in the anthracite mines in 1913 compared with 584 fatalities in 1912.

POTASH IMPORTS

The importation of potash salts for consumption into the United States during 1913 amounted to 600,000,000 lb., valued at \$10,800,000, according to W. C. Phalen. This importation is only a part, however, of the potash salts entering the country, as shown by the figures of the Department of Commerce. To it should be added the importation of kainite and manure salts, including double manure salts. The imports of these classes of material amounted to nearly 700,000 tons, valued at \$4,500,000, making a total of more than \$15,000,000 as the value of imported potash salts of all classes. The imports for consumption of materials entering largely into the fertilizer industry, plus the value of the domestic phosphate rock, reached the total value of \$52,999,469. The statistics in detail, together with others showing the condition of the German potash industry are given in the Geological Survey's report on potash just issued as a chapter of the volume 'Mineral Resources of the United States, 1913.'

The activities of the U. S. Geological Survey in the investigation of potash salts during 1913 were more restricted than in previous years. In the field, drilling was carried on in two areas, Columbus marsh and Black Rock desert, Nevada; but it was of short duration, owing to the inaccessibility of the area for an unusually long period of the year on account of heavy rains, which made it impossible to transport apparatus to the drill sites. A general plan involving the stratigraphic study of the so-called 'Red Bed' salines of certain of the southwestern states, including New Mexico, Arizona, and Utah, was begun by N. H. Darton.

COAL MINING IN OHIO IN 1913

All previous records in the coal production of Ohio were exceeded in 1913 both in quantity and value, notwithstanding that coal-mining operations like all other industries of the state were seriously interfered with by an enormous flood in March and April of that year, according to E. W. Parker. Mines were flooded and the transportation companies were practically out of business throughout a good part of the state for more than a month, so that the possible production was cut down probably 5,000,000 tons. In spite of this interruption the production increased from the previous maximum output of 34,528,727 short tons in 1912, to 36,200,627 tons in 1913, a gain of 1,671,900 tons. The increased value was \$2,861,695, from \$37,083,363 to \$39,948,058, and the average value per ton showed an advance of 3c., from \$1.07 in 1912 to \$1.10 in 1913. The average number of working days made by the employees was 206 days in 1913, against 201 days in 1912, and the average production by each man employed was 790 tons for the year compared with 758 tons in 1912. This gain in individual production was due in large part to the larger production of machine-mined coal, in the proportion of which to the total tonnage, Ohio stands well at the head among the coal-producing states. In 1913 32,642,848 tons, or 90.2% of Ohio's total production, was mined by machines. The increase in machine-mined tonnage was 2,604,017, or 932,117 tons more than the total increase. At the present time Ohio equals the excellent record of having less than 4% of the total output reported as shot off the solid, or powder-mined. Electrically-driven chain-breast machines far outnumber all other types of machines in the Ohio mines, as out of a total of 1681 machines in use in 1913, 1421, or nearly 85%, were chain-breast. Short-wall machines are growing in popularity, as indicated by an increase in their number from 106 in 1912 to 187 in 1913. The number of long-wall machines increased from 2 to 17, and the number of pick machines decreased from 77 to 56. Reports to the U. S. Bureau of Mines show that the coal-mining fatalities in 1913 numbered 165 against 133 the previous year.

Monthly Copper Production

AHMEEK COPPER MINING CO., Kearsarge, Michigan. \$1,250,000 in \$25 shares; 24,796 shares owned by Calumet & Hecla; 1800-ton mill at Hubbell; concentrate smelted by Calumet & Hecla smelter. Total in 1913, 9,100,000 pounds.

| Month. | Pounds. |
|--------|-----------|
| May | 1,178,595 |

ALLOUEZ MINING CO., Allouez, Michigan. \$2,500,000 in \$25 shares; controlled by the Calumet & Hecla, which owns 43,000 shares and \$250,000 in notes of the Company; ore is milled by the Lake Milling, Smelting & Refining Co., in which the Allouez owns half. Total in 1913, 4,091,129 pounds.

| Month. | Pounds. |
|--------|---------|
| May | 559,740 |

ANACONDA COPPER MINING CO., Butte, Montana. \$108,312,500 in \$25 shares; controlled through Amalgamated Copper Co. which owns 3,185,240 shares by Thos. F. Cole, J. D. Ryan, and Standard Oil interests; 10,000-ton concentrator and smelter at Anaconda; 5000-ton concentrator and smelter at Great Falls, Mont.; also 70-ton electrolytic refining plant at Great Falls. Production figures include copper from all companies which ship custom ore to Anaconda smelters. Total in 1913, 270,301,644 lb. copper, 64,898 oz. gold, and 10,321,296 oz. silver.

| Month. | Pounds. | Month. | Pounds. |
|----------|------------|--------|------------|
| February | 21,300,000 | April | 22,900,000 |

ARIZONA COPPER CO., LTD., Morenci, Arizona. £703,894, of which \$379,974 is in 5s. ordinary shares, £500,000 in 5% debentures; controlled by Edinburgh investors; mill at Morenci is being enlarged to 3000-ton capacity and a new 1200-ton smelter near Clifton has just been started.

| Month. | Pounds. | Month. | Pounds. |
|----------|-----------|--------|-----------|
| February | 3,063,000 | April | 3,570,000 |
| March | 3,286,000 | May | 3,092,000 |

BRADEN COPPER CO., La Junta, Chile. \$2,332,030 in \$10 shares and \$4,000,000 in 6% convertible bonds; entire stock held by Braden Copper Mines Co.; \$14,000,000 in \$5 shares; \$4,000,000 in 6% convertible bonds, \$3,000,000 7% bonds controlled by Guggenheim interests; two mills at La Junta; 3000-ton capacity smelter at Racagua.

| Month. | Pounds. | Month. | Pounds. |
|----------|-----------|--------|-----------|
| February | 2,362,000 | April | 2,720,000 |
| March | 1,801,000 | May | 2,480,000 |

BRITISH COLUMBIA COPPER CO., LTD., Greenwood, B. C. \$2,958,545 in \$5 shares; owns 63% of the stock of the New Dominion Copper Co; controlled by Newman Erb; 600-ton sampling plant and 2500-ton smelter.

| Month. | Pounds. | Month. | Pounds. |
|----------|---------|--------|---------|
| February | 572,571 | March | 682,867 |

CALUMET & ARIZONA MINING CO., Warren, Arizona. \$6,285,710 in \$10 shares; has absorbed the Superior & Pittsburg Copper Co. by stock exchange; controlled by Hoatson and other Lake Superior interests; 3000-ton smelter at Douglas. Total in 1913, 52,987,383 lb., 880,915 oz. silver, 18,989 oz. gold. Monthly returns include the Shattuck-Arizona.

| Month. | Pounds. | Month. | Pounds. |
|----------|-----------|--------|-----------|
| February | 5,948,900 | April | 5,450,000 |
| March | 5,870,000 | May | 5,480,000 |

CALUMET & HECLA MINING CO., Calumet, Michigan. \$2,500,000 in \$25 shares; controls the Ahmeek, Allouez, Centennial, Isle Royale, La Salle, Osceola, Tamarack, and Superior copper mining companies, as well as a number that are non-productive; controlled by Agassiz and Shaw interests; 2 mills on Lake Linden, capacity 15,000 tons; smelter Hubbell, Mich.; electrolytic refinery and smelter at Buffalo, N. Y.; figures include output of subsidiaries. Total in 1913, from Calumet & Hecla alone, 45,016,890 pounds.

| Month. | Pounds. |
|--------|-----------|
| May | 9,299,507 |

CANANEA CONSOLIDATED COPPER CO. S. A., Cananea, Sonora, Mexico. Capital \$20,000 in shares of \$100; entire stock owned by Greene Consolidated Copper Co.; \$10,000,000 in \$10 shares; 945,320 shares are held by Greene Cananea Copper Co.; \$50,000,000 in \$100 shares, which is controlled by Thos. F. Cole and J. D. Ryan; 30,800 shares held by the Amalgamated Copper Co.; 2 mills and smelter at Cananea, 3000-ton capacity. Total in 1913, 37,050,574 pounds. Output does not include copper from custom ores.

| Month. | Pounds. | Month. | Pounds. |
|----------|-----------|--------|-----------|
| February | 2,282,000 | April | 2,044,000 |
| March | 3,510,000 | May | 1,784,000 |

CERRO DE PASCO MINING CO., Cerro de Pasco, Peru. \$10,000,000; entire stock held by Cerro de Pasco Copper Co.; \$60,000,000 in \$1 shares which is owned by Cerro de Pasco Investment Co., which is controlled by J. B. Haggin, and Morgan estate; 3000-ton smelter at La Fundicion; monthly production figures not given out; output in 1912 was 45,000,000 lb. copper.

CHINO COPPER CO., Santa Rita, New Mexico. 4,302,700 in \$5 shares; 121,200 shares are held by Guggenheim Exploration Co.; controlled by Sherwood Aldrich and C. M. MacNeill; 5000-ton mill at Hurley, N. M.; concentrate smelted at El Paso.

Recent Publications

ANALES DE INGENIERIA. ORGANO DE LA SOCIEDAD COLOMBIANA DE INGENIEROS. Enrique Morales, director. P. 63. Ill. Bogata, Colombia. April 1914.

THE 'ITABIRITE' IRON ORES OF BRAZIL. By E. C. Harder. Reprint from *Economic Geology*, March, 1914. P. 11. Illustrated. These ores were briefly described in this journal of January 4, July 19, and November 8, 1913. They occur at Minas Geraes, Brazil, and interests connected with the St. John del Rey Mining Co. will probably mine them at an opportune time.

U. S. Bureau of Mines publications, Washington, 1914:

FIRES IN LAKE SUPERIOR IRON MINES. By Edwin Higgins. Technical paper 59. P. 34. Illustrated.

GASES FOUND IN COAL MINES. By George A. Burrell and Frank M. Seibert. Miners' Circular 14. P. 23.

COAL-MINE FATALITIES IN THE UNITED STATES. March 1914. Compiled by Albert H. Fay. P. 12. There were 200 fatal accidents as against 202 in March of 1913.

DRILLING WELLS IN OKLAHOMA BY THE MUD-LADEN FLUID METHOD. By A. G. Heggern and J. A. Pollard. Technical paper 68, petroleum technology 15. P. 26. Ill.

MINE SIGNBOARDS. By Edwin Higgins and Edward Steidle. Technical paper 67. P. 15. Illustrated. A general discussion on these necessary adjuncts to underground and surface plant.

PROCEDURE FOR ESTABLISHING A LIST OF PERMISSIBLE PORTABLE ELECTRIC MINE LAMPS. Fees, character of tests, and conditions under which lamps will be tested. Schedule 6. P. 12.

PROBLEMS OF THE PETROLEUM INDUSTRY. Results of conferences at Pittsburgh, August 1 and September 10, 1913. By Irving C. Allen. Technical paper 72. Petroleum technology 17. P. 19.

ABSTRACTS OF CURRENT DECISIONS ON MINES AND MINING. By J. W. Thompson. Bulletin 79, law serial 2. P. 140. This is another publication which should be filed in mine libraries, as showing the litigation miners are likely to get into. This journal publishes important decisions every few weeks.

PHYSICAL AND CHEMICAL PROPERTIES OF THE PETROLEUMS OF CALIFORNIA. By Irving C. Allen, Walter A. Jacobs, A. S. Crossfield and R. R. Matthews. Technical paper 74. Petroleum technology 18. P. 38. Illustrated. Methods of sampling oil by the Bureau officials, refining, and tabulation of results are given, of value to oil men everywhere.

SAFETY AND EFFICIENCY IN MINE TUNNELING. By David W. Brunton and John A. Davis. Bulletin 57. P. 271. Ill., index. This is a valuable discussion and should be in the hands of all tunnel engineers, especially for comparative purposes. It covers American tunnels described in engineering magazines, causes of accidents (falls of roof and explosives), prevention of accidents, surface equipment for driving tunnels, power required, ventilation, drilling machines, underground haulage, drilling, blasting, costs of tunneling, history of tunneling, and rate of progress, and cost of railway tunnels. There is also a bibliography, and a well selected collection of illustrations.

MATERIALS FOR THE PALAEOLOGY OF NEW ZEALAND. By James Allan Thomson. Palaeontological Bulletin No. 1. P. 104. Maps, 6 plates, index. Geological Survey, Wellington, 1913. This publication has been prepared for officers of the Survey as a reference to New Zealand fossils; for the encouragement of palaeontological work among New Zealand geologists; and for the benefit of foreign palaeontologists. A great deal of the matter is tabulated.

Industrial Progress

AMERICAN VANADIUM Co., Pittsburgh, Pennsylvania. May issue of 'American Vanadium Facts' describes use of vanadium steel in locomotives, cranes, and automobile construction.

SWEETLAND FILTER PRESS Co., New York. Bulletin K describes the lever-operated type of the Sweetland self-dumping filter. The filter is of the pressure type and designed particularly for small plants.

THE CONNESVILLE BLOWER Co., Connersville, Indiana, Bulletin No. 19 describes the Connersville valveless magma pump. Pumps supplied in either two or three lobe patterns to meet various requirements. Bulletin is fully illustrated.

THE MORSE BROTHERS MACHINERY & SUPPLY Co., Denver, furnish a stock list of machinery, including boilers, feed-water heaters, engines, motors, pumps, compressors, drills, hoists, crushers, stamps, power, and mill equipment.

TROPENAS CONVERTER Co., New York City, has issued a 50-page bulletin on the 'Manufacture of Steel Castings,' with a brief summary of bessemer and open-hearth methods of steel manufacture and a discussion of the Tropenas process are given. The bulletin is fully illustrated.

BUSCH-SUIZER BROS. DIESEL ENGINE Co., of St. Louis, has closed an order for six 600-hp. engines for use in submarine boats being built by the Lake Torpedo Boat Co. for the United States Navy. Four of these engines will be used in two of the submarines being built by the Craig Shipbuilding Company.

AMERICAN CONCENTRATES Co., Springfield Ohio. Bulletin covers the 'New Century' disintegrating and washing screen. The screen is of the trommel type, revolving a tank of water. It is recommended by the Company for use in concrete work, sizing, and other uses. Is illustrated and contains data regarding performance.

FULTON IRON WORKS, St. Louis, Missouri, has for distribution Bulletin 'A', descriptive of the Fulton-Tosi oil-engines. The engine is of the Diesel type, built in the vertical form, and of two, three, and four cylinders. The engines are adapted to many power purposes, including electric light and power plants, water works, and the like.

SPRAGUE ELECTRIC WORKS of the General Electric Co., New York. Bulletin No. 905 contains information regarding Sprague electric hoists. The hoists described are designed to fill the gap between the hand chain block and the large traveling crane. These hoists and mono-rail cranes are adapted to many uses about industrial plants, which are mentioned in the bulletin.

COLORADO IRON WORKS Co., Denver. Catalogue 12-F, 'Some Details as to Smelting Practice and Equipments.' A book of 160 pages devoted to short descriptions of lead and copper smelting in which it is aimed to furnish sufficient information to those without previous knowledge of the process to understand the underlying principles and to render a discussion of smelting intelligible. Fully illustrated and indexed.

The Guiana-Callao Gold Mining Co., operating near Paramaribo, Dutch Guiana, South America, has given THE DENVER QUARTZ MILL & CRUSHER Co., of Denver, an order for a 50-ton Denver quartz mill for immediate shipment. The same kind of mill has been in use for the past year, and this repeat order is necessary to take care of the increased tonnage. With this additional mill, the capacity will be 100 tons per 24 hours. It is planned to still further increase the capacity of the mill to 200 tons per day.

EDITORIAL

THE Administration seems to be under the impression that the mediators at Niagara Falls are merely members of Congress.

MOUNT LASSEN is in eruption and Californians are as proud as young married folk with a first baby. The presses are already busy on advertisements of the new scenic wonder, the "only active volcano in the States."

THE international character of the present psychological depression is well shown by the receipts of the Suez canal, which is a good index of trade. The traffic receipts of the canal showed a small but steady growth from 1910 to 1913; but a falling off of over 8 per cent last year.

SOME mines, like some men, have the gift of publicity, while others round out their existence in undisturbed obscurity. How many operators know, we wonder, that the Cordoba copper mine, in the south of Spain, has a monthly output greater than that of the Spassky; or that the Namqua mine, northwest of Cape Town, has a greater monthly output than the Wolverine.

TAXATION is always a tender subject that often evokes hard feelings. The Union of South Africa receives six-tenths of the profits of the Premier diamond mine, and the question has lately arisen as to whether the Government is entitled to levy an income tax on the remainder. As a result, the Botha ministry, which was seeking to impose the tax, has been defeated in the House of Assembly.

MINING lawyers who had followed the case were not greatly surprised that the United States Supreme Court found in favor of the Southern Pacific in the oil land suit brought by Burke. The only really new point decided was that oil is a mineral and therefore that known oil land is mineral land. That the Government alone has the right to question title, once patent has been issued, is not new, and that acceptance of classification by the Government at the time patent was issued was final, except on showing of fraud, is also old doctrine. In the cases still to be heard, and which are on suits brought by the Department of Justice, this question of fraud will be crucial. Incidentally there are technical questions of application of

the statute of limitations, but practically the point to be determined is whether Southern Pacific officials knew, and concealed their knowledge, that the lands in question were oil-bearing at the time they were claimed as non-mineral. This is a question of evidence.

CONTINUOUS operations are the aim of all good managers, and costs are usually lowered in proportion as demurrage is decreased. In this number, Mr. Huxley St. John Brooks lets his fancy play with the theoretical ideal, but practically unattainable, completely continuous gold mill. In a later number Mr. Maurice Summerhayes will give a detailed account of the good results actually obtained by the continuous process at the Porcupine Crown Mines in Ontario, where it has now been in operation long enough to make the study of results especially significant.

OIL MEN on the Pacific coast have become so used to big wells that even the Lakeview No. 2, flowing 30,000 barrels per day, has created little excitement. Elsewhere it is different, but then conditions differ too. All Japan was fluttering last month when the Nippon Oil Company brought in a 14,000-barrel well about 10 miles from Akita in the Echigo field. But then the total daily production of Japan had previously been but half that and the largest individual wells before had yielded but 300 or 400 barrels per day. American operators are interested in the new Japanese discovery because the Nippon Oil Company adopted the California rotary rig and took over a crew of drill men from this country two years ago, since when their results have been greatly improved. A big oilfield in the Orient would help all oil operators, since it would encourage more of the steamers to burn petroleum.

IN a recent editorial we mentioned the names of many of the prominent graduates of the School of Mines of Columbia University which recently celebrated its fiftieth anniversary. Through inadvertence we omitted four men who are not only among the foremost mining engineers, but also loyal supporters of their *alma mater*, Messrs. T. H. Leggett of the class of 1879; T. B. Stearns, 1881; George S. Rice, 1887; and R. M. Raymond, 1889. Many of the other graduates of the School of Mines have attained distinction in fields not directly concerned with mining, such as Messrs. Lenox Smith, '68; L. P. Gratacap, '76; Marcus Benjamin, and William Strieby, '78; N. L. Britton, Arthur Hollick, and R. E. Mayer, '79; C. A. Meissner, '80; Howard Van Sinderen, '81; F. B. Crocker, C. B. Going, and A. J. Moses, '82; D. E. Moran, W. Fellows Morgan, and C. E. Pellew, '84; I. H. Woolson, '85; E. J. Lederle, and A. M. Ryon, '86; L. McI. Luquer, '87; James Maclay, '88; E. W. Guiterman and H. P. Whitlock of the class of 1889. Other well known engineers whose names come to mind are Messrs. W. B. Potter, '69; Arthur F. Wendt, '72; J. T. Williams, '73; A. F. Schneider, '76; C. L. Constant, Ralph Nichols, and W. H. Radford, '77; R. E. Booraem, and Y. Hasegawa, '78;

G. S. Raymer, '81; C. Q. Payne, W. F. Staunton, and F. W. Traphagen, '82; J. H. Banks and W. H. Weed, '83; S. S. Fowler, Robert Mulford, Frederick Roeser, T. E. Snook, '84; H. L. Hollis, C. L. Miller, E. A. Wiltsee, and F. M. Watson, '85; H. D. Conant, A. W. Jenks, J. J. Ormsbee, and H. H. Porter, '86; E. Z. Burns, H. C. Mannheim, and F. M. Simonds, '87; J. S. Appleby, '88; and P. L. Fearn of the class of 1889. To name the men of the large classes since 1890 would make too serious inroads on our space.

Transitions in Copper Metallurgy

A decade ago it was clearly recognized by everyone that the growing use of copper for industrial purposes would make necessary a great increase in its production. It was equally evident that no great bodies of comparatively rich sulphides or native copper, such as until then had been the mainstay of the industry, were likely to be found. Universal attention was directed toward the large deposits of 'cupriferous pyrite,' as they were generally termed. Meanwhile a group of metallurgists, Messrs. L. T. Wright, W. H. Freeland, F. R. Carpenter, Robert Sticht, Herbert Lang, and many others, had been busy developing the technique of the metallurgical operation of cheaply smelting ore consisting largely of pyrite, marcasite, or pyrrhotite. Nearly everyone regarded pyrite smelting without coke as the metallurgy *par excellence* of the immediate future.

Meanwhile an apparently small discovery had been made. 'Cupriferous pyrite' proved to be a figment of the imagination, the ores so designated being actually pyrite with chalcopyrite or it and other copper sulphides disseminated throughout them. It was further found that copper sulphides not infrequently occur disseminated through rock masses, chiefly igneous intrusives or the adjacent rocks, so as to form large bodies of low-grade ore. A second group of engineers, chief among whom was Mr. D. C. Jackling, saw the new possibilities which this opened. Cheap smelting of such material, silicious rock containing disseminated sulphides corresponding to a copper content of 25 to 50 pounds of copper per ton of ore, was out of the question, but if it could be cheaply mined and cheaply concentrated many tons into one, making a reasonable saving of the copper present, low-cost smelting would not be essential.

Thus two sharply contrasted methods of treatment are involved: on the one hand small-scale mining, the production of the ore in lump form, and the smelting of the whole mass, utilizing the heat of the sulphur present in order to economize in the use of fuel; and on the other hand large-scale mining, cheap crushing to small size, concentration (more than twenty tons being concentrated in one in some cases), roasting of the sulphide concentrate, and smelting in reverberatory furnaces. The success of the latter method hinges on the percentage of the copper present which

can be recovered by concentration. As is well known, careful large-scale experiments demonstrated that two-thirds of the copper present could be recovered by wet concentration. On the basis of a cost of 42 cents per ton for mining, 28 cents for transportation, and 41 cents for milling, and the concentration of nearly twenty tons into one, the whole operation can be conducted at a profit, even with material containing only 30 pounds of copper per ton. On this basis the relatively higher cost per ton of material smelted in the reverberatory furnace becomes of minor import in the total cost.

Several other factors contribute toward the increased and increasing favor with which reverberatory smelting is regarded. Mr. E. P. Mathewson has discussed with authority the causes which have led to this growth. Another factor, to which attention has been drawn by Mr. Lloyd, is the improvement in roasting practice. When the control of the temperature and air supply during roasting is faulty, a certain amount of ferric oxide and of ferrite of iron is produced, and additional reactions in the laboratory of the reverberatory are made necessary, thus decreasing the speed of smelting as compared with the treatment of material in which all the iron is present in the ferrous state. As a matter of practical operation, the use of liquid petroleum or powdered coal has cut down the fuel cost, and the use of boilers in the exit flues, by recovering the heat of the escaping gases and returning it to the power-plant as steam, has made a further important reduction. The reverberatory is a convenient place for disposing of the increased quantity of slag made by the converters since the addition of silicious ore to the matte charge became general practice. Above all, it handles without difficulty the finely divided concentrate which is the necessary product of the method of treatment mentioned above, and similarly disposes of the dust accumulations yielded by other departments of the plant, such as the roasters. The most recent phase of development is the use of flotation to recover the copper content of the ore. This makes even finer crushing necessary and accentuates the advantages of the reverberatory for the treatment of material in a fine state of comminution.

Blast-furnace smelting of lump ore has many advantages, which it can scarcely be necessary to mention, but is subject to the limitation that even under the most favorable conditions a considerable proportion of the ore will be of smaller size than desired. This may be sent directly to the blast-furnace, with the result that the speed of smelting is decreased, which amounts to increasing the overhead costs, and a large quantity of flue-dust is produced. This can be caught in dust-chambers, but if put back into the blast-furnace without further treatment, is merely blown out again in a sort of perpetual cycle. It may be agglomerated in brick presses, using a suitable binder, agglomerated by the use of converter slag, or sintered by one of the various processes. All the operations add to the total cost and somewhat complicate

the work of the plant. With the exception of the latest methods of sintering, they are all unsatisfactory, and the tendency of present practice all seems to be toward the extension of reverberatory smelting. In large plants coarse material is smelted in the blast-furnace while reverberatories take care of the blast-furnace flue-dust and the fine ore or concentrate. Where the amount of finely divided material is too small to justify the construction and operation of a reverberatory, the sintering of fine ore and flue-dust is an efficient way of meeting the problem. But where, as in the plant recently built at Hayden and the one now building at Globe, all the material to be smelted is finely divided, the reverberatory alone, coupled with the present very efficient roasting technique, serves to meet the situation.

Thus a decade of time bridges over three sets of problems in the metallurgy of copper. The readjustment of smelting problems which grew out of the exploitation of the disseminated copper ores has already been discussed. But, as always in human endeavor, the solving of any important problem merely leads up to the recognition of another. The financial profit resulting from the exploitation of the disseminated ores does not serve to obscure the fact that one-third of the copper content escapes recovery. In addition, large ore reserves of oxidized copper minerals are known to exist in various places, and these are not amenable to profitable treatment by any present method. The use of wet methods for the recovery of copper from its ores has been proposed ever since early times, and have been successfully practised in a few places where local conditions favor their use. Generally speaking, however, they are complicated and require a nice adjustment of mechanical equipment to chemical reactions. Except upon a large scale, they are, for general practice, an economic impossibility, but the readjustment of modern conditions seems to be tending toward a state of affairs where wet methods become feasible. The number of processes proposed is legion, but leaching with sulphuric acid is the rule in present work. The precipitation of the copper from the pregnant solution is a vital problem. It can be done by the use of metallic iron, or by electrolysis, but the difficulty is to attain a low cost. Both methods are about to be put into operation on a large scale, and in a year or two our knowledge will be more nearly complete than now. Sulphuric acid, either for leaching or for other methods of chemical attack, seems likely to remain the chief reagent; for the sulphuric content of the fume escaping from smelter stacks is everywhere a problem, and its utilization for the manufacture of sulphuric acid, some of which may be used in the treatment of oxidized or roasted sulphide ore, is likely to be one of the lines along which the copper metallurgy of tomorrow may develop. Thus along all three lines definite and notable progress is being made in the work of adding to the world's metal supply by utilizing lower and lower grade material already known and available.

Flotation Tests at Mt. Morgan

By WILLIAM MOTHERWELL

The Mount Morgan gold mine in Queensland, Australia, which was discovered about 30 years ago, is believed to be the richest individual gold mine ever found, having produced over \$70,000,000 worth of gold to date, besides copper. In its early stage, the ore, which carried hundreds of ounces to the ton, was crushed with stamps and amalgamated, but the recovery was not especially good. Subsequently, and until seven years ago, all the ore was dry-crushed in ball-mills, roasted, and leached with chlorine solution in open brick vats and the gold precipitated on charcoal. At that time the copper content of the ore was negligible. This is one of the few large gold mines in the world that never had a cyanide plant.

About eight years ago, a large body of rather silicious cupriferous sulphide ore was found in the mine. Blast-furnaces were erected, and the less silicious ore, which contained about \$10 gold, 4% copper, and 45% silica, was, and still is, being smelted. The more silicious or so-called 'mundie' ore, carrying about \$15 gold and 1% copper, was then dry-crushed, roasted, leached with sulphuric acid, and copper precipitated on scrap iron, subsequently leached in the same vats with chlorine solution, and gold precipitated as before mentioned. About 18 months ago the gold content of this 'mundie' ore began to decrease, and the copper content to increase. For this and other reasons it was deemed advisable to cease this method of treatment, and the last of the chlorination works were shut down.

It now became necessary to find a profitable method of handling this class of ore. As iron-bearing flux has to be brought a long distance, and as the ore carries about 70% of insoluble, smelting would be too expensive. There is believed to be at least 2,500,000 tons* of this class of ore in the mine, assaying roughly \$6 gold and 2% copper. This is in addition to the so-called 'copper ore' which is being smelted. It may be explained that there is no 'carbonate zone' in this mine. All the copper is in the form of chalcopyrite. The gold is very fine.

Minerals Separation Experiments

A few years ago some experiments were made by crushing in ball-mills and concentrating on Wilfley tables, but they were not successful. Last year it was decided to make a thorough trial of the Minerals Separation process, and a small testing plant was erected in the laboratory. At the same time a full-sized experimental unit, capable of treating 300 to 400 tons per 24 hours, was erected in one of the abandoned chlorination plants. Both sets of experiments were carried out by the metallurgical staff of the Company. After they were finished, a representative of the Aus-

tralian branch of Minerals Separation, Ltd., paid a visit to the mine and conducted a few tests, which confirmed the results obtained by the mine staff.

As mentioned in the Company's annual report, these flotation experiments were successful, the extraction being higher and the costs lower than expected. The Company is now building the first unit of a plant to treat 1000 tons per 24 hours. The ore will be crushed by rock-breakers, Symons disc crushers, rolls, and tube-mills. It will then be concentrated on Wilfley tables, after which it will go through a second set of tube-mills, thence to the flotation machines. It is presumed that no royalty will be payable on the Wilfley concentrates. The concentrate will either be briquetted or sintered in a Dwight-Lloyd machine, and smelted in blast-furnaces along with the 'copper ore' and iron-stone and limestone fluxes. The Company has no reverberatory furnaces.

Application of Flotation to Gold Ores

A flotation plant is being erected at the Falcon mine, Rhodesia, to treat ore containing gold and copper. With the exception of the Mt. Morgan, the Etheridge, and the Great Fitzroy mines, Queensland, I have not heard of the flotation process being used successfully to treat ore containing an appreciable amount of gold. The Elmore thick oil process was installed at the Lake View Consols gold mine, Kalgoorlie, several years ago, but was not successful, as the ore was not suitable, and unsuccessful experiments were made by Minerals Separation, Ltd., on ore from the Lancefield mine, Western Australia, which contains mispickel. The Elmore vacuum process was installed at the Cobar gold mines, New South Wales, and at the New Ravenswood gold mines, Queensland. Both these mines contain copper in the form of sulphide, as well as gold, but the plants only ran a few weeks. I was informed that the plant at the former mine (where the ore contains about \$8 gold and 1.5% copper) gave a fair recovery of copper, but left too much gold in the tailing or left enough copper in the tailing to prevent profitable cyanidation of the gold.

To return to the Mt. Morgan mine, the laboratory apparatus had a capacity of one pound of ore at a time, and the results now being obtained in the experimental mill approximate closely those obtained in the laboratory. The object of concentration was, of course, to obtain a concentrate containing as much gold, copper, and iron, and as little silica as possible, commensurate with a good extraction of the gold, because it was found that the less silica the concentrate contained the poorer was the extraction of gold. It costs 13 cents to flux one unit of silica, and it was necessary to steer a middle course. Experiments made with

*The long ton, 2240 lb., is used throughout this article.

Sonstadt solution on ore from one part of the mine showed that clean quartz (after separation by specific gravity from all mineral) contained not less than \$1.50 gold per ton. In practice, of course, it is impossible to float all the mineral and sink all the gangue.

The agitator in the laboratory plant was at first run at 1100 r.p.m., but was afterward reduced to 800. Tests were made with pulps of different proportions, each separate pulp being agitated for the same length of time, that is, 6 minutes, and it was found that there was not much difference, in the extraction of gold and copper, between a pulp containing three parts solution to one of ore, and a pulp containing seven parts solution to one of ore. A pulp of 1 to 1 was too thick and gave poor results. In practice, the thinner the pulp the smaller the capacity of the flotation machine. Tests were also made to ascertain the effect of agitating for different lengths of time. Two tests were made in the laboratory of which I have a note: one for 10 minutes and one for 15 minutes. The ore contained \$6.50 gold and 2% copper; 12% of this sample would remain on a 60-mesh screen. The first one gave a concentrate containing \$22.70, 9.4% copper, and 18% insoluble, with an extraction of 51% of the gold and 84.5% of copper. The second gave a concentrate containing \$20.20 gold, 7.8% copper, and 27% insoluble, with an extraction of 64.5% of gold and 91.8% copper. The gold left in the tailing was probably in the gangue, as the extraction was poorer than usual. As a rule, the longer agitation and separation are continued, the more silicious the concentrate is. In practice, the length of treatment is regulated by the thickness of pulp and the number of boxes in the flotation machine. Tests made to ascertain to what degree fine crushing was necessary showed emphatically that the ore must all pass through a screen of 60 holes to the linear inch if a good extraction is to be obtained, and that the finer it was crushed, at any rate up to -120 mesh, the better the extraction was. Tests showed that when using eucalyptus oil there was no advantage in using an acid solution, but that, on the other hand, slight acidity did no harm. Much of the copper pyrite in the ore readily floats on water without any previous agitation. On treating ore containing \$25 gold direct by agitation and flotation, without amalgamating or concentrating on tables, it was proved that fine free gold can be floated by using eucalyptus oil.

Use of Essential Oils

Many oils were tested, and, generally speaking, it was found that only essential oils gave a coherent froth and good extraction, other oils like petroleum, oleic acid, and lubricating oils tending to form granules which sank. The best results were obtained from eucalyptus, closely followed by 'Essential C' and *Pinus laurus vulgaris*. Oleic acid, which was used for years at Broken Hill on zinc ore with hot solution, and gave good results when tried on this ore with neutral and acid solutions, gave an enormous froth and floated

most of the silica. A mixture containing 95% of eucalyptus and only 5% of oleic acid gave a concentrate containing 47% silica, showing the power of the oleic to float silica. Experiments were afterward made with a mixture of oils, and one combination (known as Mt. Morgan mixture) was found to give a better extraction of both gold and copper than any of the individual oils, and at less expense. When the sample was all crushed to pass 80 mesh, an extraction of 80% of the gold and 90% of the copper could be obtained every time, with a concentrate containing about 25% insoluble, which can be reduced to 10% by re-treatment. Hot solutions and a solution containing 1% of common salt were found to be detrimental to good recoveries.

Recovery by Flotation

A test on a sample, crushed to pass a screen of 120 holes per linear inch, containing \$37 gold and 4.8% copper, gave a recovery by flotation alone of 90% of the gold and 98.5% of the copper, but left \$8 gold in the tailing. The concentrate carried 44% insoluble matter, which could be reduced by re-treatment. A different oil (eucalyptus) would have given a poorer recovery and a cleaner concentrate.

Tests made on ore containing \$9 gold, 3.5% copper, and 45% insoluble, showed that after crushing to pass 60 mesh and treating by direct flotation, an extraction of 82% of the gold and 96% of the copper could be obtained, with a concentrate containing only 21% insoluble. No doubt with finer crushing even better recoveries would be had. These results leave tables and vanners far behind. It was found decidedly advantageous to re-use the solutions.

A Wilfley table was erected in the mill, some tests made, and the tailing treated by flotation in the laboratory. Sometimes these tailing samples were dried before flotation, and sometimes they were not. It was invariably found that a better extraction was obtained from those which had not been dried, as no matter how carefully the operation was conducted, some of the iron pyrite got sufficiently oxidized to resist flotation, and it carried some of the gold.

In some of the tests the crushed ore was concentrated by panning in the laboratory, and afterward subjected to flotation. In this case the water in the laboratory was used, which did not come from the same source as the water used in the mill. It was noticed that the longer the sample was allowed to remain in the water after panning, the worse the subsequent flotation was. For example, where flotation took place immediately after vanning, the residue assayed \$2.60 gold and 0.30% copper, but where tailing from panning was allowed to remain under water for 6 hours before flotation, the residue assayed \$3.10 gold and 0.67% copper. An analysis of this water was made, and this incident shows what might happen in a mill where the ore is in contact with bad water for some hours before reaching the flotation machine, such as the time it is going through rolls, Chilean

mills, tube-mills, and classifiers, over tables and through thickening devices, and perhaps through secondary tube-mills. The water in question was neutral, both before and after coming in contact with the ore.

Some tests were made both in mill and laboratory in which air was drawn into the agitation boxes through pipes fixed vertically in the corner with the top open to the air and the bottom ending in a bent pipe terminating under the impeller of the agitator. No improvement was, however, noticeable.

Grading tests were conducted on crude ore and flotation products. They showed that as regards crude ore, after crushing either in mill or laboratory, the finest grade of concentrate was the richest and the coarsest grade of tailing was richest, both in gold and copper. The fact that the finest grade of tailing was the poorest shows that this process will float the finest sulphides successfully.

Crushing Plant

In the experimental mill the ore is crushed in rock-breakers and Krupp dry-crushing ball-mills without drying. This plant was formerly used to crush oxidized ore for chlorination and, being on the spot, it was naturally utilized in preference to buying new machinery. The crushed ore drops into a bin at the bottom of which are two Challenge feeders. These deliver the ore into a launder where it is met by a stream of water which carries it direct to a six-compartment Minerals Separation machine. Each spindle is driven by a half-crossed belt, thus eliminating the noise and grease incidental to the old Broken Hill method of gearing. The machine is of the Hoover single-level type, by which one man can attend to all the flotation boxes. The concentrate was collected at first in circular wooden vats with filter-bottoms of coco matting, and later in shallow rectangular concrete tanks which formed part of the old chlorination works. The whole plant is extremely simple and requires very few men to run it. It has not been found practicable to use a screen finer than 35 mesh on the ball-mills. It is found that the gold, copper, and iron contents are greatest in the concentrate overflowing from No. 1 box and that they gradually decrease until No. 6 is reached, while the silica content increases from 10% in the concentrate from No. 1 box to about 50% in that from No. 6. About 56 hp. is required to drive the agitators at 350 revolutions per minute.

As it is intended to use Wilfley tables in the new mill to assist in recovering the iron pyrite in the ore for fluxing and other purposes, two of these machines were placed in the experimental mill and some tests made to find out what results may be expected of them. Taking an average of several tests on ore from different parts of the mine, the grading of the 'table feed' was as follows: 10% remained on 60 mesh, and 19% passed through 60 but remained on 120 mesh. It contained \$4.50 gold, 1.8% copper, 9% iron, and 76% insoluble. The concentrate assayed \$17 gold, 2.9% copper, 34% iron, and 18% insoluble: the recover-

ies were 33% of the gold, 13% of the copper, and 38% of the iron. No doubt, had the pulp been classified and the fine material passed over slime tables or vanners, better results would have been obtained, but the Company does not intend to use mechanical concentrators for the slime, preferring to rely on the flotation process, so it was not worth while experimenting with them.

During the flotation experiments with eucalyptus oils some tailing was produced which contained a fair amount of gold, and attempts were made to recover some of this by amalgamating and cyaniding. It was found that no extraction by amalgamation was possible, nor was any extraction by cyaniding possible without either roasting or finer grinding. On unroasted tailing assaying \$3 gold and 0.44% copper, after crushing to pass 120 mesh, separating the slime, and leaching the sand for 9 days, an extraction of only 60c. per ton was obtained with a consumption of 3.6 lb. of cyanide per ton. On a different tailing crushed to pass 80 mesh, which after slime was separated assayed \$2.90 gold and 0.30% copper, an extraction of \$1 was obtained in 5 days with a consumption of 2 lb. of cyanide.

Samples of slime were treated by agitation and washed by decantation, and gave slightly better extractions, but the consumption of cyanide went up to 6 or 7 lb. The strength of solution used in these tests was 0.10% KCN. It should perhaps be noted that all samples of flotation tailing had been dried before being tested by the flotation process.

Effect of Roasting

Two samples of sand from tailing were roasted and treated by percolation. The value was \$3. The roasting reduced the sulphur to 0.5%. Although the copper and iron were oxidized by roasting, the consumption of KCN was less than in treating the unroasted tailing, which was contrary to expectation. With three days treatment, the residue was reduced to \$1 per ton, and about one-third pound of copper was dissolved from each ton of tailing by the cyanide. The consumption of cyanide was 1.4 lb. per ton, so that the extraction was higher and the loss of cyanide less than in treating unroasted tailing. Speaking from memory, I think that attempts to regenerate the cyanide in solution by means of sulphuric acid and lime were not very successful. The solution contained 0.05 gram copper per litre.

These cyaniding tests were merely done for information, as it is not expected that the tailing from the new mill will be profitable for cyaniding. The subject of extracting gold from flotation tailing arose a few years ago at the Cobar gold mines, as already mentioned, but in that case the difficulty was overcome by selling the mine, which contained highly silicious ore, to a company which owned a smelter, and had, or thought it had, plenty of basic ore for flux. Unfortunately, the amount had been overestimated and the problem is still unsolved—but that is another story.

Sinking Through Sand in the Lake Superior Region

By P. B. McDONALD

The various troubles caused by quicksand overburdens at iron mines in Michigan and Minnesota sound like exaggerations to men accustomed only to hard-rock practice. In recent years iron ore deposits, which formerly seemed impossible to mine at a profit, have been worked on a large scale by the aid of expensive development work. The easily mined orebodies, and particularly outcrop bodies, were mined in early days, but present operations include diamond-drill prospecting followed by elaborate construction work and costly preparation for extracting large tonnages at low costs. The depth of the sand and glacial drift overburden is surprising, being often over 100 ft., frequent-

an exceptionally large boiler plant and powerful sinking pumps, and found that there was no use for them. The most popular method has been the drop-shaft in its several variations. According to one method, the whole timber structure is dropped as digging proceeds, in which case the heavy timber sets may be added to at the top, with perhaps additional heavy weights of iron or sand to force the structure down. If the ground penetrated before the quicksand is reached, is stiff or contains boulders, the timber structure may get stuck on one side, requiring a blast to free it. Usually the cutting-shoe at the bottom is covered with steel plate and pointed, but when it has seen a little service it may be turned back, twisted, and bent out of all recognition. Another modification of the drop-shaft method requires only a short section at the bottom which drops. If necessary, this is forced down by jack-screws, and then at every foot gained, a solid 12-in. timber is put in all around. (See Fig. 1.) The timbers may be bolted together and interior bracing in the shaft may be necessary to strengthen the structure.

Labor Requirements

The men who work at sinking should be quick and resourceful. Sometimes the timber structure will buckle or twist out of all shape before the miners can brace it. Or the sand may start to run and cave in a regular flood, filling the shaft perhaps 25 ft.; in such a case the miners should be good ladder climbers. Economy depends, of course, upon having as little sand to hoist or pump as possible; thus the work must be slow and cautious. After the shaft has filled by a flood, the water is slowly pumped out, and the sand shoveled and hoisted. If the sand rushes are not too serious, they may be encouraged frequently, rather than waiting for big ones to occur which may wreck the timbering.

Many mines on the Mesabi and in Michigan have trouble with sand in their drifts and stopes, where the ore lies under the sand, and the operators want to get all the ore they can without causing a run of sand. One mine at Negaunee, Michigan, has a sand-run every little while, which occasionally catches miners and stops operations for a day or two, if not longer. It sometimes happens that a miner is killed in this manner.

The first shaft in a low district of thick overburden will tend to drain the entire vicinity, and the water in the neighboring lakes may commence to go down. Under such conditions the mining company will probably contract for a concrete drop-shaft sunk by the caisson method. In spite of the high price of such work (generally reported to be \$500 per foot) this plan has advantages since the shaft is usually completed in a few

FIG. 1. SHAFT SINKING WITH DROP SECTION.

ly over 200 ft., and occasionally 300 ft. If a company has proved by churn and diamond-drilling 2,000,000 tons of iron ore and then stopped exploration, since that quantity insures sufficient ore for a first-class plant, it is usually in a hurry to sink a shaft and see what more there is, as well as desirous to see returns from the investment. In several such instances the quicksand and water difficulties delayed progress for a year or two and caused tremendous expenditures even to get the shaft to bedrock, perhaps 150 ft. At one or two properties, foreman after foreman failed, until finally a particularly ingenious or persevering 'mine captain' succeeded.

All sorts of expedients have been tried; using hay or straw to hold the sand back, first sinking a small auxiliary shaft for pumping, and even the freezing process was tried. In some cases so much pumping was done that it seemed the whole locality would be pumped away, and a great pit grew around the timbered shaft. On the other hand, a company, anticipating trouble from quicksand and water, installed

months and is practically water-tight, sealed to bed-rock, and ready to commence sinking in rock. The Foundation Company does not pump water, but holds it back by compressed air. Thus, when the mining company begins sinking in rock, it may have trouble in the first few feet due to water, the iron ore being essentially an oxidized formation, and water gets through it easily. The most troublesome part of the caisson work is generally at bedrock, because sand and pebbles may grade into hardpan and broken 'ledge' so gradually that it may be thought bedrock has been struck when it is in reality not solid enough to warrant sealing. That is where the Foundation Company has trouble, and where the cost per foot may be several thousand dollars. The contractors sometimes lose money, as is believed to have been the case at the Morton shaft on the Mesabi where a huge sphere of concrete was rolled on the concrete drop-shaft to force it down. The caisson method is good for quicksand, but after penetrating a stratum of quicksand if a hardpan or stiff clay stratum is cut, the work goes very slowly. The 'sand-hogs' can dig only intermittently and the shaft will refuse to drop from friction on its sides.

The final pressure of air used at the Rogers shaft near Iron River was about 45 lb. per sq. in., which is not far from the limit of human endurance; each man worked two 40-minute shifts per day. Men are required to be in fair health, to have a good heart and digestion, and not to be drinking, to go into compressed air. It is not dangerous to an ordinary individual, although some people get in the air-lock and when the air is turned on, decide that their constitution is not good and ask to be let out. The feeling is similar to that of being under water, and the voice sounds similar when talk is attempted. Due to the compressed air, candles several inches in diameter are necessary and even these burn very fast. Care should be taken not to allow the clothes to catch fire, as they will burn as though soaked in oil. In entering the caisson, several minutes are taken in the air-lock where the ordinary man holds his nose and blows into his ears by puffing his cheeks out; a foreman who goes in and out a half dozen times a day may just rub his hand across his nose a couple of times. Before going in, you can test the tubes between your ears and your mouth, by holding your nose and forcing air into your ears until each one 'clicks', showing that the pressure is greater on the inside than on the outside of your ear drum. In the air-lock, as the compressed air gets into your system, the pressure on the inside of your ear-drums becomes the same as on the outside; it is only at first that it is greater on the outside. That most painful affliction the 'bends' or its worse form 'paralysis', which is due to coming through the air-lock too quickly on the way out, is said to be caused by bubbles of compressed air in the blood, which should have been given time to work out by the lungs and skin when in the air-lock. 'Bends' in the arms is

common, paralysis in the legs is worse, and when attacked in the muscles of the stomach one generally asks a bystander to kindly hit him on the head with an axe. Men with the 'bends' are taken into a hospital-lock, a steel cylinder where compressed air can be turned on and then allowed to escape very slowly. The 'sand hogs' drink warm coffee before going down.

The work of 'sand-hogs' at the bottom of a shaft is merely to pick and shovel; the dirt is hoisted out in a bucket. A dozen men will work a shift in broken bed-rock or in hard pan, and scarcely any difference can be seen; perhaps a couple of buckets will be sent up. Man's strength seems greatly diminished in the high air pressure. To keep the compressed air from escaping through the sand, a layer of clay is sometimes plastered around the bottom of the steel shoe. In spite of that, bubbles will frequently be seen coming out of the ground a hundred feet from the shaft. It usually keeps an air compressor or two busy supplying the pressure for the caisson, as the air leaks out through the sand and the walls of the caisson. The air is let out of the caisson when it is necessary to let the concrete shaft drop down the distance that has been excavated, perhaps a couple of feet; otherwise the air pressure holds the shaft up. Of course, the men are out when this is done, as the water floods in and has to be blown out.

Prospecting for the precious metals has been intermittently carried on for many years in Yell county and elsewhere in Arkansas, and last March reports were received by the U. S. Geological Survey that several rich prospects had been located. G. S. Rogers, a geologist of the Survey, was immediately detailed to investigate these reports, and by taking reliable samples for assay, he determined the probable importance of the find. His report indicates that none of the prospects are of economic importance, and that while small pockets of ore may possibly be found in this region, there is little chance of developing a mine.

Small sizes of anthracite coal, such as buckwheat and smaller, now sold in competition with bituminous coal and at prices below the actual cost of production, may, in the opinion of E. W. Parker, of the U. S. Geological Survey, become more valuable as raw material for the briquette manufacturer. The output of these small sizes produced by crushing large coal to obtain the domestic grades exceeds 20,000,000 long tons annually, exclusive of 3,000,000 to 4,000,000 tons annually recovered from culm banks by washeries.

Coal imports into Argentina in 1913 totaled 4,046,278 metric tons. Imports by countries were as follows in 1912 (latest figures available): from Germany, 56,450; United Kingdom, 3,499,989; United States, 115,901; other countries, 35,616; total 3,707,956. Bituminous coal from the United States in 1913 amounted to 279,993 tons, valued at \$890,247.

The Chilean Nitrate Industry—III

By LESTER W. STRAUSS

The labor question on the nitrate fields has been a serious factor in the production of salitre. Shortage of labor means less output and higher wages, and causes less effort on the part of those employed. The men employed are Chileans, Bolivians, and Peruvians. About 54,000 peones are required in the industry. In 1912, 47,800 were employed, averaging 54 tons salitre per man per year. There is a continual movement, or migration, of the men; within the past two years practically all of the Peruvians (only found in the province of Tarapaca) have returned to their native soil—a result of misguided persecution. The Bolivians are returning to their homes lured by the increasing wages in the tin mines. The Chileans (from southern Chile), obtained in the *enganching* system (hiring through advancements made in wages), are attracted by the higher wage which prevails on the nitrate fields as compared with that at home. As the railroad construction (especially the Longitudinal railroad) is practically finished, more men should be available. The rate of wages varies from 5 pesos (\$1.10) to 7 pesos (\$1.54) per day.

The laborer is brought to the province and his fare is paid. On the field he can hire himself out wherever he chooses; no deduction is made from his wages to pay expenses and no contract is made. The expenses of his family are also paid and every inducement is made to keep him from returning southward. The *enganching* organization has a fund of 200,000 pesos (\$44,000) cash invested in advances.

Nitrate Propaganda Association

The Nitrate Propagation Association (Asociación Salitrera de Propaganda) was formed in Iquique (and later, 1896, legalized by Congress), as a separate organization from the combination of the several nitrate companies, to limit production and sustain prices. These limitation endeavors, started in 1884, were in general disastrous as prices fluctuated beyond their control. The Association keeps statistics in which are recorded the transfer of properties, names of new properties, sales and changes of oficinas, besides the figures of production, exportation, and consumption of salitre, record of the meetings held and all information for the good of the cause, especially the progress made in the consumption of the artificially made fertilizers, and advertises the benefits of its products abroad. Offices have been opened in the principal nitrate consuming countries, and considerable activity is displayed in this propaganda.

The board is composed of seven members from the Tarapaca fields, two from Tocopilla, three from Antofagasta, and two from the Taltal districts. The Association is sustained by the income resulting from the 3¢d. (3¼c. collected per quintal exported. This was originally 1¢d. (1¼c.). Due to excessive production,

large stocks abroad, speculations, and the fact that a detrimental amount of perchlorate of potash (so harmful to vegetation) was found in some of the salitre, the price fell to 4s.6½d., in April 1898. This was record bottom price and caused the worst panic ever experienced in the industry. Two later attempts to sustain prices failed severely, so that at present the Nitrate Propagation Association directorate manages the combination, whose upkeep is sustained by another 1½d. charged per quintal exported.

Production Statistics

According to the quarterly circular of the Asociación Salitrera de Propaganda, there were 158 oficinas registered in 1911, of which only 111 exported, these shipping 53,250,327 quintals. In 1912 there were 170 oficinas, but only 126 exported, these shipping 54,197,439 quintals. The exports from the various ports for 1911 and 1912 are given below in quintals.

| | 1911. | 1912. | Oficinas 1912. Producing. | |
|---------------------------|------------|------------|------------------------------|------|
| | | | Total. | ing. |
| Pisagua | 2,917,881 | 2,391,282 | ... | ... |
| Junin | 1,806,961 | 1,806,961 | ... | ... |
| Caleta Buena | 5,693,165 | 5,543,030 | ... | ... |
| Iquique | 11,831,273 | 12,993,761 | ... | ... |
| Total from Tarapaca .. | 22,249,280 | 22,724,223 | 99 | 74 |
| Tocopilla | 7,440,189 | 6,188,023 | 10 | 10 |
| Mejillones | 7,694,606 | 7,539,235 | 29 | 21 |
| Antofagasta | 6,759,701 | 8,119,096 | | |
| Caleta Coloso | 3,125,436 | 3,130,773 | 14 | 8 |
| Taltal | 5,981,115 | 6,496,099 | 18 | 13 |
| Total from Antofagasta .. | 31,001,047 | 31,473,223 | 170 | 126 |
| Total exported | 53,250,327 | 54,197,439 | | |

Nitrate ground is not obtainable by the usual methods of denouncement. Every year certain areas are advertised for sale, by auction, at a minimum bid price of a certain number of centavos (of the gold peso of 18d. (36c.) per quintal (metric) of salitre producible, the highest bidder obtains the tract offered. The ground has been previously reported on by government engineers, who state a minimum production of a certain number of million (metric) quintals of salitre possible. With this as a basis, and taking into consideration the economic situation of the property as regards railroad facilities and more especially water supply, the price per metric quintal of salitre recoverable is arrived at. The yearly auctions are limited to properties not having a greater total output than 14,000,000 metric quintals (that is, 220.46 lb. each) of nitrate, and to be made up in lots of over 7,000,000 quintals 'output capacity'; where the ground does not permit of this minimum, less may be offered. The transfer of title is under the responsibility of the state.

Entry to the bidding must be accompanied by a deposit, to the order of the Director of the Treasury, for an amount equal to 10% of the minimum price. This deposit is presumably returned to the non-successful bidders. The deeds of sale must be signed within 30 days after the day of sale, and the balance of the sale price then paid in first-class 90 days drafts on London; failure to appear within the time specified, or if the time set is ignored, means the forfeiture of the deposit. The state does not hold itself responsible for the quantity of nitrate said to exist in the ground on the statement, and plans, of the Delegación Fiscal de Salitreras. The date of the auction is published in the newspapers of Santiago, Valparaiso, and Iquique, and abroad in London, New York, Paris, Berlin, and Hamburg. The Government donates money, from time to time, for works beneficial to the industry. For example, it gave 3,800,000 pesos of 18d. gold, or \$1,378,000, for a water line for Iquique, and grants a subsidy to the Nitrate Association (begun in 1906 with £30,000) of £40,000 yearly, which will probably be increased to £50,000 in view of the heavy expenses incurred by the Association abroad. It has been stated that the Government has received as revenue, from the export tax, more than three-fold the amount distributed as dividends to the various nitrate companies, but has contributed less than one-third of the money spent in propaganda. In 1912 the contribution per quintal exported (46 kg.) was raised from 5s. to 3d. (about £85,000 being received in 1912 from the salitre exported); but this increase (between £14,000 to £15,000) is still insufficient to permit extending the propaganda on the scale deemed advisable and necessary. The total amount contributed by the industry from 1891 to 1913 is stated as £730,727 13s.3d.; the Government has contributed £354,726 7s.4d. during the same period. It is interesting to note the comparison, for 1910, of the sum spent for propaganda by the Potash Syndicate and that for the Salitreras account:

| | Value. | Propaganda. |
|------------------------|-------------|-------------|
| Potash Syndicate | £ 5,000,000 | £150,000 |
| Salitreras | 22,500,000 | 100,000 |

Ammonium Sulphate Competition

With respect to ammonium sulphate, the prices, based on the unit of nitrogen, are practically equal, nitrate being slightly cheaper, but the difference in the amounts of propaganda money spent is considerable. In 1911 salitre averaged £9 17s.11d. per ton and ammonium sulphate £13 15s.3d. The Nitrate Association is straining every effort to keep out competition from ammonium sulphate, its most important rival, and the other artificial nitrogen products, including the calcium nitrate made in Norway. In endeavoring to centralize the selling, and to keep prices fairly fixed, the Association is displaying a financial foresight which must bring about gratifying results.

The well arranged and amply tabulated statistics, issued tri-monthly, show practically every country on the globe a consumer of salitre. Below are given the

principal consuming countries, in order of their respective consumption of Chilean salitre for 1911 and 1912, in quintals.

| | 1911. | 1912. |
|--|------------|------------|
| Germany | 16,154,100 | 19,816,650 |
| United States: | | |
| East coast | 11,147,963 | 8,388,000 |
| West coast | 1,116,552 | 1,195,811 |
| France | 7,359,975 | 7,703,550 |
| Belgium | 6,601,050 | 6,732,225 |
| Holland | 3,143,250 | 3,931,425 |
| England | 2,007,000 | 2,196,450 |
| Italy | 1,165,050 | 967,950 |
| Scotland | 881,550 | 789,525 |
| Spain | 195,075 | 294,525 |
| Austro-Hungary | 114,750 | 154,575 |
| Denmark | 74,700 | 104,850 |
| Sweden | 51,525 | 112,950 |
| | 50,093,440 | 52,388,486 |
| Other countries | 2,011,093 | 2,550,151 |
| Chile | 76,944 | 51,467 |
| Total | 52,181,477 | 54,990,104 |
| Stock on hand (in the various foreign ports) | 36,823,212 | 35,204,913 |

American Consumption

The United States agricultural industry is said to consume over \$150,000,000 of fertilizing material annually. Voorhes has stated that its yearly consumption of nitrate might reach 2,000,000 tons (metric) (43,500,000 quintals, 46 kg.) if 10 lb. was used per acre of ground cultivatable. This appears a low estimate of the amount actually required per acre.

The highest price that nitrate sold for, on the coast, was 9s.6d. (\$2.28) per quintal; the low mark (in 1898) was 4s.6½d. (\$1.08). The average for December 1913 was 7s.11.78d. (\$1.92). The quotations refer to duty paid, immediate delivery alongside ship.

The approximate life of the nitrate fields has been estimated with wide ranges of possible existence. Several years ago, 20 to 50 years, allowing for increasing consumption, was suggested, but this is too low an estimate. Later critics (in 1907) suggested 88 years for the supply known to exist at that time, not allowing for a large area that was predicted to exist but not yet discovered. Investigations made by government engineers, of known and prospected ground, give the following quantities, in quintals or 46 kg.:

| | |
|--|---------------|
| Tarapaca | 725,300,000 |
| Toco (Tocopilla) | 614,925,000 |
| Antofagasta | 714,184,000 |
| Aguas Blancas | 1,083,032,000 |
| Taltal | 2,087,603,000 |
| Chañaral and Copiapo | 183,700,000 |
| Total | 5,408,744,000 |
| Nearly 249,000,000 metric tons. | |
| The present tonnage has also been estimated in the | |
| | Metric tons. |
| Province of Tarapaca | 35,000,000 |
| Province of Antofagasta | 185,000,000 |
| Total | 220,000,000 |

Making allowance for a yearly increase of consumption of 1,000,000 quintals (46 kg.), the above figures indicate 60 years as the probable life. It must be noted that there are several factors which would augment the life of the industry, and therefore make the present day prognostications doubtful figures. Reduction of the 28d. export tax would render available much ground that cannot be opened up under the existing duty, which is a heavy item in the selling cost; if the Centralization Committee can effect a fixed price agreement, or if higher prices prevail, ground of doubtful value might be exploited and thus additional area thrown open. Improvement of the present working methods, as regards mining and treatment, would make additional tracts, at present too low grade, available. The tonnage tied up in abandoned workings, and old tailing, or residue dumps naturally falls into the latter category. There is no doubt that any or all of the above changes can be reasonably effected and in turn result in prolonged life to the industry. These innovations will come soon. The nitrate business is in a transition stage, and the next two years will see marked changes. Considerable experimenting is being done in treatment schemes to increase extraction and lower expenses.

There is good reason to believe that the industry has not reached its maximum; it will naturally be affected by rise and fall in prices, as without a combination among the producers, it is the low-cost producing oficinas that must survive, by reason of large production, with the fluctuating selling prices.

Average Prices

Approximate half-yearly average prices for immediate delivery of salitre (alongside), duty paid, per quintal, 101.4 lb., are as follows:

| | First six months: | | | Second six months: | | |
|------|-------------------|-----|------|--------------------|-----|------|
| | s. | d. | \$ | s. | d. | \$ |
| 1900 | 4 | 11½ | 1.19 | 5 | 6 | 1.32 |
| 1901 | 6 | 3½ | 1.46 | 6 | 7½ | 1.59 |
| 1902 | 6 | 7 | 1.58 | 6 | 5¾ | 1.56 |
| 1903 | 6 | 5 | 1.54 | 6 | 11¼ | 1.66 |
| 1904 | 6 | 9¼ | 1.63 | 7 | 10 | 1.88 |
| 1905 | 7 | 6½ | 1.81 | 7 | 8 | 1.84 |
| 1906 | 7 | 11¼ | 1.91 | 8 | 10 | 2.12 |
| 1907 | 8 | 7 | 2.06 | 8 | 8 | 2.08 |
| 1908 | 7 | 10¼ | 1.89 | 7 | 6 | 1.80 |
| 1909 | 6 | 10¾ | 1.65 | 6 | 9¾ | 1.64 |
| 1910 | 6 | 6¾ | 1.58 | 7 | 1¼ | 1.70 |
| 1911 | 7 | 1¾ | 1.71 | 7 | 6¾ | 1.81 |
| 1912 | 7 | 6¼ | 1.81 | 8 | 6¼ | 2.04 |
| 1913 | 8 | 3¼ | 1.94 | 7 | 9½ | 1.87 |

The average selling price in London for 1912 was 10.014s. \$2.40; the sea freights fluctuated from 19s. in January to 29.75s. in October; the average for the year was 26.27s. per ton (\$6.30).

The foregoing descriptions have been based on notes taken in November 1909 at Agua Santa, and the generous information given and suggestions made by J. T. Humberstone resident manager at Agua Santa, also data supplied by A. F. Syers-Jones, resident manager

in Iquique, and C. C. Aitken, manager at Caleta Buena, of the Agua Santa Nitrate & Railway Co.; also private communications and suggestions from S. H. Loram, of Valparaiso. The tri-monthly circulars of the Nitrate Association Propaganda have been freely drawn upon for the statistical data and general information of the industry. The works of Samper and Michels (1903), later (in 1907) translated into Spanish by Gandarillos and Chigliotti, and Darapsky's 'Das Department Tal-tal' form excellent reference books on the subject.

The annual statistics for 1912, published by the Bureau Central de Estadistica, states that the value of the metallic and non-metallic production in the country was 372,667,774 pesos of 18d. (\$134,158,599). The value of the nitrate produced was 297,372,750 pesos of 18d. (\$107,054,190), which represented nearly 80% of the total valuation given. The Chilean peso (paper) fluctuated rapidly. In 1913 the exchange varied from (high) 10.2d. in January to (low) 9.27d. in November; the average was 9.78d. (\$0.196). It has been taken at 11d. in this paper. A pound (£1) has been taken equal to \$4.80.

Curtailment of Production

In August 1913 there was a movement on to restrict production and thus prevent a further drop in the low price (7s.6d. alongside, \$1.80, duty paid, immediate delivery). This step had been suggested so as to bring about better prices. The rate of production for the first six months has been equivalent to 60,000,000 quintals per year. A restriction of 10%, which was then decided upon, was expected to bring up the selling price the desired 6d. per quintal. In fact the price came up 5.78d. It would seem feasible, on the part of the Government, to arrange a sliding scale for the export tax (below 28d. when prices are below a certain quotation, and continuing in a decreasing proportion as prices decline) that would give the producers more margin when prices abroad make operating expenses show a loss. In 1913, from January 1, prices declined from 8s.3d. to 7s.6.67d. in July, then rising but suffering a decline in November. The average for December was 7s.7.78d. In view of the competition with the artificial fertilizers it behooves the Government to exert considerable effort to aid the propaganda, so that Chilean salitre can retain its present position in the world's products.

The following figures are of interesting comparison, the figures being in quintals.

| | —January to July— | | For the year |
|---------------------|----------------------|----------------------|-----------------------------------|
| | 1912. | 1913. | July 1, 1912 to June 30, 1913. |
| Production | 26,856,455 | 30,092,777 | 59,450,462 |
| Exported | 22,627,094 | 26,322,039 | 58,492,375 |
| World's consumption | 38,432,229 | 38,389,687 | 54,947,562 |
| | — Per quintal | | |
| Average price | 7s. 6¼d. (\$1.81) | 8s. 0¾d. (\$1.94) | |

The above shows that the consumption for the trading year (July 1, 1912, to June 30, 1913, inclusive) was slightly over 3,500,000 quintals less than the export,

and 4,500,000 quintals less than the production. These figures indicate the urgent need of restricting the output.

For 1913 the figures were as below. The importance of the restriction of output is brought out by them even more emphatically.

| | 1913 (calendar year). | |
|---------------------------|-----------------------|--------------|
| | Quintals. | Metric tons. |
| Production | 60,249,865 | 2,771,400 |
| Exported | 59,529,121 | 2,738,200 |
| World's consumption | 55,562,219 | 2,555,800 |

Compared with 1912, the following table is of interest, figures being in quintals:

| | 1912. | 1913. | Increase. |
|--------------------------|------------|------------|-----------|
| Production | 56,214,140 | 60,249,865 | 4,035,725 |
| Exported | 54,197,439 | 59,529,121 | 5,331,682 |
| World's consumption..... | 54,990,104 | 55,562,219 | 572,115 |

The total nitrate produced from 1809 to 1914, in round figures, might have been 48,500,000 metric tons.

Iodine to the extent of 1,010,186 lb. was produced and all exported in 1912; it is a product derived from the nitrate and is an additional source of revenue to the Government, the export tax being 10.4d. (21c.) per pound. Its exportation is limited by the 'Iodine Combination' so as to keep up prices, so only a small proportion of the possible output is made. Those oficinas (40 in 1912) which have caliche high in sodium iodate are the favored producers. The Domeyko oficina in the Antofagasta district has a capacity of 400,000 lb. of iodine per year. The method of manufacture consists in treating the mother liquors from the nitrate crystallizing vats or tanks, which contain iodine principally as sodium iodate, with a mixture of sodium bisulphite, and is carried out as follows: the bisulphite of soda is prepared by burning a mixture of nitrate of soda and coal 'fines,' the soda so formed is leached out, decanted, and sulphurous acid gas (made by burning native sulphur in iron stoves) is passed through in excess, thus forming bi-sulphite. To a given quantity of mother liquor a sufficient amount of the above mixture of bisulphite of soda is added until the temporary brandy coloration (due to free iodine) has disappeared, and the solution is clear, then about 20% of its volume of fresh mother liquor is added through which the iodine is precipitated; the required proportions being determined by tests made beforehand. The iodine is allowed to settle, is filtered, pressed, and the cakes so formed, containing about 75% iodine, are placed in one-ton charges in iron retorts connected with condensers, made of earthenware drain-pipes about 30 in. diameter, placed on a gentle incline. The retorts, after careful luting with clay, are gently fired until the iodine is all driven over. The apparatus is allowed to cool several days, after which the pipes are opened at night when the temperature is cooler, and the crystallized iodine, 99.6% pure, is shoveled out and packed in 100-lb. barrels, that are afterward sewed in rawhide for transportation. The cost of extraction varies from 1.2 to 1.4d. per ounce; the price has been put up to 9d. The analysis of a sample of mother liquor used for iodine extraction is as follows:

| | Tarapaca plant. Grams per litre. |
|--------------------------------|-------------------------------------|
| Nitrate of soda | 306.61 |
| Chloride of soda | 108.45 |
| Nitrate of potash | 121.79 |
| Perchlorate of potassium | 15.90 |
| Sulphate of magnesia | 50.25 |
| Chloride of magnesia | 49.97 |
| Iodate of soda | 9.73 |
| Sulphate of lime | 3.55 |
| Borate of soda | 2.83 |
| Boracic acid | 21.96 |
| Total | 699.94 |
| Water | 728.56 |
| Weight of one litre | 1419.50 |

Safety in Crucible Practice

*The graphite crucible is not strong even when new; it naturally weakens under the severe treatment which it must endure in service. Nevertheless, care and skill in its use makes the graphite crucible a comparatively safe vessel in which to melt and handle molten metals. The crucibles should be inspected carefully for cracks and other superficial flaws, and only those crucibles which seem to be in sound condition should be put into service. It is especially important to examine crucibles for dampness; and if the condition of the packages or of the car in which they have been shipped indicates that they have been wet in transit, the crucibles should be put aside, either to be returned to the maker or to be specially treated. Moisture in the crucible is a great source of danger when the crucible is exposed to high temperatures, for the heat rapidly converts the moisture into steam, and the latter, unable to escape quickly, causes slight explosions in the crucible walls, which weaken or fracture them. The remedy is gradually to drive out all moisture before charging the crucible, and to prevent further absorption of moisture. When received, crucibles should be stored in a warm, dry place, preferably in an oven on the roof of a continuously operating core oven, and shut off from moist air as much as possible. The best results are obtained when the temperature in the storage oven is maintained at about 250°F., at which temperature crucibles will not absorb moisture. Waste gases from furnaces or from ovens may be advantageously used for this purpose; when these gases are moist, however, they should not come in contact with the crucibles, but should be conducted through the furnace walls. The use of damp high-sulphur coke or coal or of fuel oil containing excessive moisture should be avoided, both in the storage oven and in the melting furnace.

In April the new mill of the Shamva mine, Rhodesia, treated 39,012 tons of ore averaging \$3.79 per ton. Residue assayed 20c. per ton. All working expenses were \$1.88 per ton and the profit was \$53,000.

The Largest Electrically Operated Gold Dredge

By W. H. GARDNER and W. M. SHEPARD

*Owing to the areas of rich gravel deposits in the world being limited, the large dredging companies have turned their attention to the problem of handling extensive low-grade gravels. Powerful dredges, with a capacity of 10,000 cu. yd. or more per day, have thus been evolved to treat this material at low operating costs. Such a boat is Yuba No. 14, constructed for the Yuba Consolidated Goldfields Co. by the Yuba Construction Co. of Marysville, California.

Dredging in the Yuba River

The Yuba river, draining a region from which the early output of California gold was largely derived, was considered as a dredging field as early as 1900.

and on the American river at Folsom, fleets of gold dredges were operating by this time, but in point of extent and value the goldfield along the Yuba river is unequalled.

In 1912, the construction of Yuba No. 14 was first projected. It was determined to build this dredge entirely of steel, the longer life and practically negligible fire risk being the determining factors. The life of a dredge is limited by the life of its hull, and the steel hull, while more expensive, increases the life of the dredge, from 10 years, with a wooden hull, to 15 years or more. Steel housing and steel gold-saving tables were provided to decrease risk of loss by fire and for other reasons. Buckets of 16-cu. ft. capacity

YUBA GOLD DREDGE NO. 14 IN OPERATION.

While good gold content was found, the ground was thought too deep to dredge, and it was several years before it was considered possible to construct dredges that could dig deep enough to handle this ground. Yuba No. 1 and No. 2, 7-cu. ft. dredges, were then constructed to dig to a depth of 65 ft. Six more dredges of improved design followed soon after. The ground was rich, one of the dredges alone once clearing more than \$400,000 profit in a single year. Later, four more dredges, having somewhat larger hulls, were built and added to the fleet. In August 1911, Yuba No. 13, a 15-cu. ft. dredge with wooden hull, started work and handled an average of 280,000 cu. yd. per month at an average operating and maintenance cost of a little over 3.3c. per cubic yard. On the Feather river at Oroville,

each were designed, the expected yardage being 10,000 cu. yd. per day. A long ladder was planned, to enable the dredge to dig 70 ft. below water-level, and reach the deepest bedrock. The latest improvements in electrical equipment and control were incorporated in the plans of the dredge, to help reduce the operating cost to a minimum. An increased area of gold-saving tables was provided, to secure the maximum gold recovery. While no experimental features were introduced in the design, the machinery was strengthened in many places. As a result, Yuba No. 14 stands as the largest and most modern gold dredge in the world. It was built on the Yuba river a little farther up river than the other dredges operated by the Yuba Consolidated Gold Fields Co., at a total distance of about 14 miles from Marysville.

*Abstract from the *General Electric Review*.

A brief description of the engineering and mechanical points of this dredge are as follows:

Steel Hull

Perhaps the most important and interesting feature of Yuba No. 14 is its steel hull. This is 155 ft. 6 in. long, 58 ft. wide, with an additional overhang of 5 ft. on each side to increase deck area, and is 11 ft. 6 in. deep. It is made entirely of steel, and is the first steel-hull dredge to have a deck of steel plating. Particular attention has been given to the design of the hull. It

400-HP. MOTOR OPERATING THE BUCKET LINE.

has been so constructed that all of the heavy stresses are distributed over a series of fore and aft and transverse trusses. The vertical sides of the hull form the girders which carry the concentrated loads near the edges of the main deck. The bottom of the hull is framed in such a way that the upward pressure of the water is carried to the main fore and aft trusses and to the sides, allowing the hull to be as light as possible and yet giving it at the same time ample strength to withstand the stresses incident to the operation of the dredge. Following out this same scheme, the spuds are directly in line with the fore and aft trusses.

The bow gantry, the truss from which the ladder is suspended, is of particularly heavy steel construction, and the weights of the bow and stern gantry, added to the weight of the hull, show a grand total of 1,562,546 pounds.

The housing, carrying out the general plan of the dredge, is also of steel fireproof construction. It is made up of two sheets of 22-gauge steel between which is a 1/4-in. sheet of millboard. This insures absolute fire protection, and gives a maximum insulation, keeping the dredge interior warm in winter and cool in summer. This is an important item, for warm weather in the field is particularly torrid owing to the gravel and sand bars along the river.

The digging ladder, of the plate girder type, is one of the heaviest yet designed, and to enable the dredge to dig 70 ft. below water-level has a length of 133 ft. 6 in. between tumbler centres. This girder is 10 ft. in depth. Not counting the ladder rollers or bucket line, this ladder weighs 125 tons. The bucket line is composed of 87 buckets, connected in an endless chain. The bucket bottoms are of a special nickel-chrome steel.

cast with the hoods integral. The lips and bushings are of manganese steel, and the bucket pins are of a specially heat-treated oil-tempered nickel-chrome steel. The wear on the bucket line of a deep digging dredge is very great, and hence only the highest grade steels can be used in its construction. This bucket line complete weighs nearly 203 tons, a weight of over 4600 lb. per bucket.

The ladder hoist winch is operated by the main motor through a pulley shaft on the main deck, this shaft being also belted to the main bucket drive above. The main digging motor, which is of 400-hp., is thus used to raise and lower the ladder, and to drive the bucket line.

The main drive, consisting of the upper tumbler shaft with its two 12-ft. diameter gears, the intermediate shaft which is made in two separate lengths to allow room for the long hopper, and the pulley shaft with its two differential pinions and 12-ft. diameter pulley, is rigidly supported by the steel main gantry and the upper chords of the fore and aft main trusses, this rigidity serving to hold the gears accurately in mesh and to preserve the alignment of the shafting.

The screen, a revolving cylinder of perforated high carbon steel plates, is 50 ft. 6 in. long and 9-ft. diameter, and is stiffened by heavy longitudinal steel angles extending between the supporting tread rings at each end.

Gold Saving Tables

The gold saving tables and supports are made entirely of steel, and divided into two separate banks 6 ft. apart. In each bank there are 14 transverse sluices on each side of the dredge. The three upper sluices extend through the side of the house where each one discharges into separate outboard longitudinal sluices that extend to the stern. The other 11 cross-sluices discharge into seven inboard longitudinal sluices, the discharge from which is carried about 25 ft. astern by overhanging steel tail-sluices, or delivered back of the spuds as may be required. The total table area is 7540 square feet.

The two spuds are built up of structural angles and plates, have a cast steel point, are 30 by 60 inches in section, and 60 ft. long, and weigh together 160,800 pounds.

The stacker is exceptionally long, measuring 137 ft. between pulley centres, for when digging to the maximum depth of 70 ft. the boulders have to be stacked very high. As is usual, it is of the lattice truss type.

The swing winch is an eight-drum winch, two of the drums being for spares (lines which are used for repair work and miscellaneous purposes), two for the bow swinging lines, two for the lines that raise the spuds, and two for the stern lines. This winch weighs 41 tons. The design of winches of this type has been worked out particularly well, and in spite of continuous use and hard wear, repairs on such a winch are small.

Since Yuba No. 14 will not dig with a high bank, as do some of the Natomas Consolidated dredges, no

monitor pump is carried. There are, however, three Yuba Construction pumps, one a 14-in. high-pressure horizontal centrifugal pump, used for supplying water to the screen, one a 14-in. low-pressure pump, used for supplying water to the tables, and the third, a 6-in. two-stage pump supplying water under a 125-ft. head to the dump hopper.

By a system of levers the motion of the drums on the swing winch, the speed change on the same winch, and the operation of the main drive clutch, the ladder hoist clutch, the ladder hoist brake, and the main drive brake, are all controlled from the winch room, requiring a total of 23 levers. These are in addition to the control of the main drive and swing winch motors. From the winch room the bucket line can be raised or lowered, stopped or set in motion, the spuds can be raised or lowered, and the dredge moved by either the bow swing, head, or stern lines.

The electrical equipment of Yuba No. 14 is of interest in that it represents something of a departure from the equipment heretofore considered standard for California gold dredges. This departure from former practice was made in the light of experience gained in the operation of four dredges of the largest type which were built by the Yuba Construction Co. for the Natomas Consolidated of California, and one similar dredge built for the Yuba Consolidated Gold Fields. All electrical plant was made by the General Electric Company.

Power is supplied by the Pacific Gas & Electric Co. and is a three-phase, 60-cycle, 4000-volt current. The power is brought on board the boat through 750 ft. No. 0, B. & S. gauge, 3-conductor cable, each conductor being stranded and insulated with $\frac{5}{32}$ -in. 30% Para rubber, conductors twisted together, rounded out with jute and covered with a layer of $\frac{1}{8}$ -in. varnished cambric. Over this is a layer of jute and the cable is armored with No. 10 B.W.G. armor put on with short pitch. This cable is insulated for 4500 volts working pressure. The shore cable is brought aboard the dredge on pontoons and enters a switch house on the upper deck near the stern of the dredge, where there is installed an automatic 300-ampere, 7500-volt oil switch with hand-operated remote control. The switch is mounted on pipe framework away from the panel carrying the operating lever. There are installed in this switch-house two 4400/110-volt, 200-watt potential

transformers with fuses, and two 150-ampere current transformers. The secondaries of these transformers are connected to indicating instruments mounted in the winch room. From the switch-house the current is fed through triple conductor varnished cambric cable in conduit to the primary side of the main transformers. These consist of three 200-kw. oil-cooled transformers, 4000-volt primary and 460/230-volt secondary. In addition to the main transformers, there is installed one 15-kw. 4000-volt primary 230/115-volt secondary oil-cooled transformer to supply lights. From the sec-

DREDGE IN COURSE OF CONSTRUCTION, SHOWING STEEL HULL.

ondary side of the main transformers various feeder circuits supply the different motors, triple conductor varnished cambric being used in iron conduits.

The control panel for the main drive or digging motor, and for the winch motor, is placed in the winch room, as is also the instrument panel. The instrument panel contains the following instruments, which are supplied, as mentioned above, from the instrument transformers placed in the entrance switch-house: One 5-ampere-alternating current ammeter with 150-ampere scale, one 175-volt alternating current voltmeter with 8-point potential receptacle and plug, one alternating current polyphase indicating wattmeter with 1200-kw. scale. The readings of these instruments give the total input to the dredge.

The double-circuit control panel for main drive and winch motors has the following equipment: One 60-ampere alternating current ammeter (winch motor); one 5-ampere alternating current ammeter, 800-ampere

scale (main drive motor); one 200-ampere automatic oil switch with double-coil series trip (winch motor); one 600-volt 800-ampere automatic oil switch with double-coil trip (main drive motor); and two 800-ampere current transformers in main drive motor circuit.

The panels for the pump motors are placed on the lower deck, the starting compensators for the pump motors being mounted alongside the panels. These compensators are all provided with inverse time-limit relays. The pump motor panels consist of the following: Two 3-phase 2-circuit motor panels, each panel mounting two 500-volt 200-ampere level switches controlling the high-pressure, the low-pressure, the 6-in. 2-stage, and the vertical pumps.

The stacker and screen motors are controlled from independent panels located in the stern of the dredge, each panel having the following equipment: One 200-

EIGHT-DRUM SWING WINCH.

ampere automatic oil switch, with 2-coil series trip, and mounting on the front of panel for one reversible type controller. The oil switch operating level is directly above the controller.

All of the panels are natural black slate mounted on pipe supports.

The digging or main drive of the dredge is a 400-hp., 514-r.p.m., 3-phase, 60-cycle, 440-volt, slip-ring, variable-speed induction motor with three bearings, pulley, and sliding rails with a master controller and contractor panels, and is provided with resistance good for continuous operation at all speeds from 50% normal to normal.

Current-Limiting Relays

The contactor equipment is provided with current-limiting relays, which limit the maximum load that the motor can take and so protect both the motor itself and the complete digging mechanism that it drives. This is of considerable importance in keeping down the cost of repairs and preventing loss of time incident to repairs. The digging mechanism is subject at times to sudden and excessive loads and without the current limiting feature provided by the contactor control the only protection would be given by the overload oil switch. Due to the annoyance of having this switch tripping out frequently it is usually set so high as to afford little protection. The current-limiting relays

also protect the motor and digging mechanism when starting. The winchmen can throw the master controller to the full 'on' position and the motor will come up to speed at a predetermined rate, which will not impose excessive stress on any part of the mechanism.

Another motor operates the winch, raises the spuds, and swings the boat. This motor is a 35-hp., 600-r.p.m., 3-phase, 60-cycle, slip-ring, variable-speed induction motor with a controller and resistance for continuous operation at from 50% to full speed. The motor is provided with pulley and base. In a few instances on smaller dredges, motors of intermittent rating were furnished for operating the winch. These motors, however, have not been found suitable for this service, as the winch operates almost continuously.

All the pump motors are squirrel-cage motors, the high-pressure pump having a 150-hp., 600-r.p.m. motor, the low-pressure pump a 75-hp., 600-r.p.m. motor, the 6-in. 2-stage pump a 50-hp., 1200-r.p.m. motor, and the vertical pump a 10-hp. vertical motor. These motors are all direct connected to the pumps and, with the exception of the 10-hp. motor, are all provided with welded end-ring construction in the rotor.

Variable-Speed Motors

These motors are of the slip-ring, variable-speed type, provided with resistance for continuous operation at from 50% to full speed and with reversible controllers. They operate at 600 r.p.m., the screen motor being 75 hp. and the stacker motor 60 hp. In most of the former gold dredges these motors were of the constant-speed squirrel-cage type. However, in the more recent large dredges, due to difficulties sometimes experienced with squirrel-cage motors on account of the heavy starting conditions and the desirability at times of running for short periods at reduced speeds, slip-ring motors with resistances for two-minute starting duty were used. In heavy work, however, these were found too light, and for Yuba No. 14, resistances for continuous operation were installed and reversible controllers used.

There is provided a 2-hp., 1800-r.p.m., 3-phase motor with pulley and base for the repair shop on board the dredge. The operating time of a dredge is between 85 and 88% of the total time. The dredge operates night and day with three shifts. The load-factor varies from 62 to 80%, depending on the character of the ground, and as the dredge operates practically every day in the year throughout its life, except the Fourth of July and Christmas, it represents an excellent load for the power company.

Yuba No. 14 was built in four months and four days from the driving of the first rivet, a remarkable time considering the enormous total weight of the dredge. All material was transported 14 miles from the railroad over uncertain roads by means of power tractors and trailers, by no means a small job when it is noted that the completed dredge weighs very close to 1994 tons.

Classification at Miami

To obtain the best possible results in the concentration of ores, it is generally accepted as standard practice that classification is essential, that the different grades of feed thus separated may be treated on different tables and to the best advantage. The methods of classification are generally hydraulic, and the classifiers are either mechanical or stationary in operation. Of the latter type, baffle and hindered-settling classifiers are being favored by the operators. After considerable experimental work at Miami during which various types of classifiers were tested, the subject of tonnage, thickness of discharge, water required per ton of solids handled, proportion of coarse material

Classification does not result from the use of hydraulic water alone, but the pots act as baffles and the staggered path of the material allows the water to wash the fine particles from the downwardly flowing coarse material, carrying them above and beyond to the next classifier. A nipple and wooden plug is used in the bottom of the classifier spigot. The opening through the plug may vary from $\frac{1}{4}$ to $\frac{3}{4}$ in.

The results obtained at Miami by the use of this classifier may be seen from the following representative tests:

FIG. 1.

FIG. 2. ARRANGEMENT OF LAUNDERS AND CLASSIFIERS AT MIAMI.

in discharge, accessibility and ease in replacement of wearing parts were subjects of investigation. The Deister cone baffle classifier, a cross-section of which is shown in Fig. 1, was found adapted to conditions and has been installed. This classifier constitutes a cast iron barrel in which hollow cones or diaphragms with slots or openings sufficiently large to permit the free passage of the coarser material are placed in an inverted position. These pots or cones are staggered, the openings in one cone being out of line vertically with the adjacent cones, thus forming baffles. In operation, the crushed material which is mixed with sufficient water to insure its movement along the launder passes down into the barrel through the openings into the cones. At the same time sufficient water is admitted through one of the side inlets of the annular waterway, and of sufficient force to separate the fine from the coarse material passing through the cones, forcing these fines to the top and on to the next classifier, allowing the downward movement of the coarser particles. The arrangement of the launder and series of classifiers at Miami is as shown in Fig. 2.

| | | | |
|-------------------------------------|--------|--------|--------|
| Tons solids per 24 hours..... | 33.60 | 37.90 | 23.90 |
| Ratio solids to water in product... | 1:1.77 | 1:2.38 | 1:2.64 |
| Hydraulic water, gallons per minute | 17.50 | 22.40 | * |
| Screen analysis of product: | | | |

| | | | |
|----------------|-------|-------|-------|
| -10 mesh | 0.10 | 0.10 | 0.00 |
| +20 " | 4.70 | 6.10 | 12.70 |
| +30 " | 37.50 | 38.60 | 44.70 |
| +40 " | 24.30 | 19.80 | 19.20 |
| +60 " | 22.00 | 19.40 | 14.50 |
| +80 " | 5.00 | 5.70 | 3.70 |
| +100 " | 2.90 | 4.10 | 2.20 |
| -100 " | 3.50 | 6.20 | 3.00 |

*Not taken.

From the results tabulated, one cannot fail but be impressed with the tonnage and ratio of solids to water in the product. From the screen analyses of the 10-mesh material it is to be remarked that in each test from 78 to 83% of the product is between 30 and 60 mesh. If curves were plotted with mesh and percentage as coördinates, the sharp rise between the +20 and +30 and sharp fall between the +60 and +80 would indicate graphically the degree of classification which is being effected.

The Han-Yeh-Ping Iron & Coal Company

This Company, as many of our readers know, owns the only modern iron and steel works in China. It has had a very romantic history which may not be so generally known.

When Chang Chih-tung was viceroy of Canton a good many years ago, he was impressed with the strategic necessity for an iron and steel works in China so that the country might be able to manufacture materials for guns and ships in the event of a foreign war. He accordingly ordered from England the necessary equipment for a small steel works. So far as is known, no effort was made to determine whether the necessary raw materials were available in Canton. Before the material was delivered Chang Chih-tung had been promoted to be viceroy of the Hu-kuang provinces and he accordingly had the material shipped along with him to his headquarters at Wuchang. There a fairly convenient site was selected on the opposite side of the river in the town of Han Yang and a plant was erected. The next thing in order was to find raw material to work on. Fortunately a large deposit of iron ore of good quality was soon discovered at Tayeh in Hupei province, so situated that it could be cheaply mined and transported. Limestone of good quality occurs in close association with the iron ore.

Coke Supply

The problem of securing an adequate supply of coke was a much more difficult one. English, German, and American coke was tried, and although it gave good results the cost was so high as to prevent any possibility of operating at a profit. Coke from Tongshan and various other places in China was tried, but while the price was lower the quality was also so much lower that there was no advantage in its use. Finally it was discovered that coke of good quality was made by the natives in Western Kiangsi province and upon investigation it was found that there existed at that place coal seams which could be mined upon a large scale and coke of excellent quality made after washing the coal. The recital of all the difficulties through which the Company passed would take too much time. The technical work was performed under the direction of Gustave Leinung, while the management was largely in the hands of Sheng Hsuan-Huai. The plant was increased in size from time to time and various changes made, until finally there were three blast-furnaces and a full set of open hearth furnaces together with rail mills and the other accessories for a modern steel plant. The enterprise was at first semi-official but later it became more of a joint stock enterprise in which Sheng had the controlling interest.

From time to time it became necessary to raise more money and loans were secured from Japanese capitalists, the Japanese being willing to advance money to the plant in consideration for receiving a favorable contract for the supply of iron ore to the Japanese gov-

ernment iron works at Wakamatsu. It will thus be seen that while the enterprise was largely in private hands, it had rather vague connections with both the Chinese and Japanese governments. The business management of the plant seems to have been poor; at any rate, the financial position of the Company seems to have become worse rather than better, and the part destruction during the revolution was a final blow which placed it in a very serious position. Since that time the Chinese interests have made strenuous efforts to raise the necessary money to pay off old indebtedness and to rebuild and equip the plant so as to do good work along modern lines. The position of the Company is so unfavorable that there was no success in getting anyone to take any interest in the matter except the Japanese. The original loan of the Japanese was to be paid back by deliveries of ore to the government steel works. However, the amount of ore taken by the Japanese has not been enough to pay off the debt, and meanwhile something like \$2,500,000 additional has been borrowed from Chinese and foreigners at rates of interest which vary between 9½ and 13 per cent.

The Japanese Loan

The Company has finally entered into an agreement with the Yokohama Specie Bank, whereby the bank agrees to lend the Company \$7,500,000 at 7% interest. This will bring the total indebtedness of the Company to the Yokohama Specie Bank up to nearly \$15,000,000. Of the new money thus provided, \$3,000,000 will be spent for new equipment and reconstruction, while the remainder will be used to pay off old debts. The terms of the agreement give the control of the Company to the Japanese; and as the iron and steel company was, and still is, semi-official in character, its becoming a semi-official Japanese enterprise is naturally the cause of much commotion in China. There has been a good deal of discussion as to whether the Government at Peking will allow the Company to consummate this agreement, and it has been proposed to have the Chinese Government take over the enterprise itself. As this would involve the Chinese Government assuming an indebtedness of something like \$25,000,000 there is naturally a good deal of objection to this course of procedure. It is known that the Chinese interests concerned have made strong efforts to persuade the Bethlehem Steel Co. to come to their rescue, but that organization was naturally averse to becoming involved in such a complicated situation. At the last report the agreement with the Japanese bank had not yet been consummated, but unless the Chinese Government is willing to come to the rescue and furnish the funds required there seems no escape from the proposed arrangement.

With a membership of over 400,000, the United Mine Workers of America *Journal* was run at a loss of \$8596 in 1913. The revenue was \$15,435.

The Mogul Mill, South Dakota

By JESSE SIMMONS

At the new plant of the Mogul Mining Co., on Nevada gulch, near Trojan, Black Hills district, a distinct departure from the customary practice of cyanidation is made. All of the ore is slimed, and treated by agitation and continuous decantation. No filter is used. Furthermore, a De La Vergne oil-engine is used as a prime mover for the steadily running machinery; the crusher and rolls are operated by electric motors, using power which is purchased from the Consolidated Power & Light Co.

The Mogul mill is so situated that bottom-dump railroad cars discharge into the crusher bin. Entries to open-cut workings are directly in the rear of the mill, on the same level as the railroad track, and a portion of the mill supply comes in one-ton mine-cars. After passing through a No. 5D Gates crusher, the ore goes by shaking feeder to a 14 by 36-in. roll, delivering a product of about 1-in. cubes. Thence it is delivered by an 18-in. S.-A. conveyor, set at an incline of 22° , to two cylindrical steel bins, 16 by 14 ft., from either one of which it is possible to feed either one of two 6-ft. Trent Chilean mills. As this conveyor discharges into the bins a sample is automatically taken by cutting across the stream of pulp every 35 seconds, making it practicable to get a close sample on a small lot of ore. Of the two Chilean mills, but one is constantly used, and the other is held in readiness and kept in full repair. Cyanide solution is added at the Chilean mill, and the product elevated in a 16-in. bucket elevator to a Dorr duplex classifier, the overflow from which goes to a 35-ft. tank equipped with a Dorr thickener; the underflow goes to a 5 by 18-ft. tube-mill which is operated in closed circuit with the classifier. The result is that a product is treated of which about 1% is coarser than 60 mesh, and 40 to 50% finer than 200 mesh. From the 35-ft. thickener, which is installed in a tank 10 ft. deep, the clear overflow solution is transferred to the zinc-boxes, first passing through a clarifying filter, and the underflow of thickened slime runs by gravity to a 15-ft. 6-in. by 16-ft. Dorr agitator, thence by gravity to a second agitator, identical in size and equipment, thence by gravity to the continuous decantation installation of Dorr thickeners in 25 by 10-ft. tanks. At No. 3 thickener, barren solution is added, and at No. 4, the last in the series, wash water is used. Between the thickeners the pulp is handled with diaphragm pumps, which, I am told, are more efficient and require less attention and far less power than air-lifts. At this plant the moisture content of the slime drawn from the thickeners averages 40 to 44%, which is probably somewhat thicker than the average in mills equipped with air-lifts, and as the efficiency of the continuous decantation process rests upon thickening the slime to the last practicable point, this would appear to be an important factor in favor of the pumps.

The only solution precipitated is that drawn off the 35-ft. thickener, amounting to about 450 tons per day, and it is naturally the richest in the mill, a portion of it having been worked forward to this thickener from the No. 3, which is the fourth in the series, and the balance of it coming from the Chilean mill by way of the classifier and tube-mill. The capacity of the plant is 150 tons per day. The oil-engine is working satisfactorily, producing power at a lower cost than it can be purchased from the electric company. This engine is rated at 130 hp., and drives the Chilean mill, tube-mill, thickener, agitators, pumps, and two 10 by 10-in. single-stage compressors. As the plant has been in commission only three months, much data are not yet available. J. V. N. Dorr is general manager; L. D. Dougan, mill superintendent; and E. R. Graham, mine superintendent.

A Car Brake

The sketch shows details of a car brake for a sub-level car, especially needed where the track is well in-

clined for down grade when carrying loads. On a long down grade, a trammer or even two trammers may lose control of the heavily loaded car.

Present exports of gold to Europe are attracting considerable notice in financial circles. During the week ended June 13, gold worth \$19,000,000 was engaged for export, which is a record. This amount was made up of several shipments. The largest cargo of gold ever carried in one lot was on the *Lusitania*, which brought \$12,361,000 to New York from London on November 8, 1907, to help relieve the panic of that year.

Mineral production of South Australia in 1913 was as follows: copper, 7161 tons, worth £488,986; gold, £27,000; silver-lead, £1100; salt, £48,750; and ironstone and limestone fluxes, £50,000. The total was £642,626, against £595,670 in 1912, and £450,054 in 1911.

Pyrite production of the United States in 1913 was 341,338 long tons, valued at \$1,286,084, a decrease of 9590 tons and \$48,175 compared with 1912.

A Continuous Process?

By HUXLEY ST. JOHN BROOKS

Needless to remark, I was a visitor at the local branch of the Ananias Club, but my friend was not only a foundation member, but rumor even whispered that he had received his diploma from the founder of the first club of Ananias, of Oyster Bay. I had just returned from Nigeria, and had not seen him for years. The talk drifted to continuous milling processes as applied to gold ores. I had remarked that nowadays it was theoretically possible to set the machinery going and then recline in the shade, except when the occasion for a clean-up arose. I had said that it only needed the introduction of some form of continuous clean-up to make the formerly down-trodden millman's lot an ideal one. Bates looked carefully around to make sure that we were alone, and then remarked: "Mind, I am telling you this in strict confidence, as I don't want it to get about till the machinery is erected and turning out the goods. The absolutely continuous mill has been invented, and right here is the boy who has done the trick."

Bates Continuous Process

"I am leaving for South America tomorrow to supervise the installation of the 'Bates Continuous Precipitation and Smelting Process' at the Engañado mill of the Sueño de Pipa Mining & Milling Co. The company possesses in the south of Ecuador one of the richest gold mines in the world, but unfortunately the climate is so enervating that it is quite impossible to induce white men to exert themselves for any length of time. Many and many a young fellow has arrived there brimming over with quiet confidence and bursting with eagerness to jump right in and show them some. But after a few weeks the climate gets in its deadly work, and the erstwhile hustler, little by little, drifts into the habit of running around all day in pajamas when he isn't reclining thoughtfully in a hammock absorbing the cooling drinks obsequiously proffered him by the hospitable natives."

"At first the company tried training native talent for the work, but they are such inveterate socialists, and believed so thoroughly in the common ownership of gold, that the idea fell through. Then they attempted to bring over skilled Chinese from Johannesburg, but the government refused to permit their importation. The mill was closed for several years, till the introduction of the continuous processes of agitation and decantation induced them to start up again. It was then found possible to run the mill with only one white man per shift, who did little else but sit in a natty office and read the Sunday papers. The old manager suddenly making up his mind to pull out for 'God's country,' a new man full of life and vim was imported from North America. Though warned by the New York directors what to expect, he was profoundly moved by what he saw when he arrived. With a choking

voice he said to one of the mill shift-bosses: 'See here, Mister, I don't mind your sleeping on night shift; I don't even mind your bringing your bed into the mill; but I do object to your saying your prayers before you turn in.'

"However, on the principle that the less a man has to do the less he wants to do, the unhappy victims of the enervating effects of that atrocious climate grew more and more disinclined to make up the monthly clean-up. The company were quick to see what was required. What was needed was a system of automatic clean-up; something continuous, yet fool and thief-proof. They turned to the one man in America who could help them out, and you can take it from me, sir, that one man did not fail them."

"I discarded the zinc-boxes altogether, and introduced a rotary affair filled with zinc clippings. It revolves at slow speed and the friction of the clippings against each other rubs off the precipitate as fast as formed. The gold slime falls to the bottom of the box, where it encounters a sort of Dorr thickener mechanism which draws it off at under 40% moisture. From there it passes to a drier, and thence to the 'Bates Patent Continuous Bullion Furnace.' This is a kind of combination Erlenmeyer furnace and continuous classifier. It is a tubular affair set at a slight pitch from the feed to the discharge end. The precipitate, automatically mixed with the required flux, which is fed from a hopper, enters the furnace a little at a time. The layer of fluxed precipitate is so thin and the heat so regulated, that the gold is melted almost instantly and rolls in globules toward the discharge end. By reason of its greater specific gravity, it escapes from the furnace, but the furnace itself is made to revolve at such a rate that before the slag has time to escape it reaches the top of the furnace, where it is scraped back to the slag discharge outlet by means of rakes. From the furnace the bullion passes, always by gravity, to a simple continuous cupellation furnace of my own design. From this machine the refined bullion passes to the 'Bates Collector.' There, after being cooled to a pasty condition, it is forced through a narrow slot and issues in the form of a ribbon. It is wound on spools, each containing approximately a thousand dollars worth of output. Once a day (or less, according to climatic conditions) the manager manipulates the combination lock, takes out the output, and transfers it to the safe, where it remains until the day for shipment. When the mill is running you will see a 200-ton mill run by one white man, working one hour a day. Everything else is done by unskilled labor of the rawest description."

Pondering all this, I wonder was Bates pulling my leg or was he pulling the company's. I am still wondering.

Labor employed at Panama on March 25 totaled 33,201 persons, an increase of 1400 compared with that of February 25.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Valuing Dredging Ground

The Editor:

Sir—I venture to ask a question in connection with the article on the valuing of dredging ground, by Mr. Decoto, in your issue of May 9. In this article an example is given of the calculation of average value for an area, 'A', shown in the accompanying sketch, from six test holes on boundary lines and two in the

centre of the area, arriving at an average value of 72.42c. for the area, as per clipping herewith, or 62.90 as corrected below, to correspond with diagram of

| Area A | | 7..... 60 × 20 = 1,200 | |
|--------|------------------|------------------------------|-----------------|
| 1..... | 130 × 40 = 5,200 | 8..... | 42 × 30 = 1,260 |
| 2..... | 35 × 30 = 1,050 | | |
| 3..... | 60 × 20 = 1,200 | 210 | 13,210 |
| 4..... | 50 × 20 = 1,000 | Dividing 13,210 by 210 gives | |
| 5..... | 40 × 20 = 800 | an average value of 62.90 + | |
| 6..... | 50 × 30 = 1,500 | for area 'A'. | |

Mr. Decoto. The reason for giving hole No. 1, of exceptionally large value and depth, and situated at a corner of the area, equal weight with holes No. 4 and 5 in the centre, is not made clear.

From inspection of the diagram it seems that holes No. 4 and 5 might be taken as representative of the squares shown hatched in the accompanying sketch,

and, the area of one of these squares being taken as unity, holes No. 2 and 7 should represent an area of 0.5, and holes No. 1, 3, 8, and 6, of 0.25. The average value for the whole area on this basis would then be calculated as follows:

| | | |
|--------|--------------------------|------|
| 1..... | 130 × (40 × 0.25 = 10) = | 1300 |
| 2..... | 35 × (30 × 0.50 = 15) = | 525 |
| 3..... | 60 × (20 × 0.25 = 5) = | 300 |
| 4..... | 50 × 20 = | 1000 |
| 5..... | 40 × 20 = | 800 |
| 6..... | 50 × (30 × 0.25 = 7.5) = | 375 |
| 7..... | 60 × (20 × 0.50 = 10) = | 600 |
| 8..... | 42 × (30 × 0.25 = 7.5) = | 315 |

Sums 95 5215

$\frac{5215}{95} = 54.89c.$ average value for area 'A', or 8.01c. less than corrected value, which is 17.53c. lower than the value given in the article referred to. What would be standard practice in this case?

H. N. HERRICK.

Berkeley, California, May 11.

[Mr. Herrick's point is well taken, and we trust may lead to further discussion of this timely subject. EDITOR.]

Prospecting—Present and Future

The Editor:

Sir—I read with much interest the discussion in the columns of the *Mining and Scientific Press* under the heading 'What Is the Matter With Prospecting?' Coming from a number of the foremost engineers and mining men of the country, such an expression of opinion is of great value. However, owing to the necessity of brevity of each individual contribution, it seems that some phases of the question could hardly receive the attention they merit, and the writer has ventured to enlarge upon certain points suggested both by the discussion and by his own experience in the field.

The term 'prospecting' as used in this connection implicitly includes not only the search for new mining districts, but also the operations of individuals and corporations who are looking for promising properties in any stage of development. As to the men engaged in present-day prospecting, the old type of prospector is still in the field, and is still the pioneer in the business. He is usually a miner with a fondness for life in the open and a liking for the independence of working on his own initiative; added to this is the ever present hope that over the next range may lie the outcrop of the next big mine. It often happens that prospectors of this class are familiar only with certain types of ore deposits, and on going into new country they may overlook indications which are outside the field of their previous experience.

An instance of this kind occurred at Ray, Arizona, in the days of the earlier development of the camp. The old prospector looked dubiously at the reddish hills, which make a rather striking showing when viewed from the higher country to the east. He said: "Young man, do you reckon they really have a copper mine

yonder! If they have, I've walked over half a dozen or more and didn't know it. No, sir! I think this is just a stock-jobbing scheme."

It is probable that the lack of a broad experience has been a decided handicap to the work of many prospectors, and for this reason some of the districts which have been more or less thoroughly prospected by men from other districts which may have differed widely in type of ore deposits, will in the future yield important discoveries. In the earlier days when transportation was not easy, men moved only relatively short distances in the search for new mines, and it is sometimes possible to trace the advance of miners from a parent district by the methods used in the development of several camps in a more or less related series. Naturally, new things in the way of outcrops, or mode of occurrence of orebodies, or mineralogical characteristics of the ores were overlooked. A striking case of this kind was that of the Camp Bird mine, if the story is a true one: that one of the claims later forming part of the central holdings of the company was being worked as a lead-silver prospect, while the gold-bearing quartz was thrown over the waste dump.

After the 'old-timer' comes the 'practical mining man.' He has usually had extensive experience in the operation of mines, and, 'having worked himself out of a job,' has been sent to find a new mine. It is the men of this stamp who are responsible for the development of some of our largest mines. In fact, it seems that they have been more uniformly successful than anyone else. They are usually men of good judgment; they have the practical knowledge to back up their original decisions, and are ready to work on something that 'looks good.' Further, knowing by experience the necessity of taking chances in development work, they are usually willing to do so; while the purely technical man becomes scared because he cannot see the situation worked out by tape, assays, and slide rule. Finally, such a man has the confidence of the people for whom he has proved a successful manager or superintendent, and when in need of financial assistance has to waste no time in looking for it.

Finally come the men who are employed as 'field men' by the large companies. They have not had the extensive practical training of the type above mentioned, and in many cases their technical training has not been such as to fit them especially for the judgment of new properties. In the beginning they are often young graduates whose experience has been confined to work in minor positions on one or two properties. After spending several years in the field at the expense of the company, they have added considerably to their knowledge and may then begin to be useful. Men of this class, working for the most part on salaries, are deeply imbued with the idea that they must 'play safe.'

A few years ago I met an engineer on a property that had many of the indications of a big low-grade copper deposit. This man said: "Yes, it does look good, but it isn't a sure thing. If I turn it down,

my clients will not lose any money, and if it should turn out well, the chances are that they will never connect it with this examination." One of the reasons why more new mines are not discovered is that much of the money available for their development is in the hands of ultra-conservative technical men who are not disposed to jeopardize their salaries or fees by taking chances.

Another reason may be found in the methods of these men in office and field. A great many of the properties 'examined' are eliminated by the reading of reports in the city office. For the most part, reports submitted in this way are poor material upon which to base an opinion. They are often written by men untrained in that type of work, and in many cases are obviously based upon a very superficial study of conditions. In fact, it would seem that most of the people with properties to sell have little or no idea as to what is necessary in a good report.

The field methods of the average examining engineer are also open to criticism. He is usually sent to visit a certain mine in a district, and arrives after a more or less trying trip. He often has to put up with unpleasant living conditions which inevitably affect the thoroughness of his work and may bias his judgment, and in addition he may be in a great hurry to get to some other camp or back to the city office. Then there is the almost universal attitude, adopted by such men, of looking for reasons to reject the property. It is much easier to find these than to go over the ground in detail and pick out the points which may offer chances for success. These are not obvious in most cases, or the mine would not be on the market. Much time and money are wasted by engineers making hasty trips here and there over a wide field. They do not become familiar with the details of any one district, since they look only at the one property to which they have been sent. No matter how experienced a man may be in such work, his judgment must be superficial if he does not give the time necessary to familiarize himself with local conditions.

Turning from a criticism of present-day methods to a consideration of the possibilities of the future, there is such a wide field that only a few points can be presented here. In the first place, it must be admitted that the field is not so attractive as it was thirty years ago. Most of the striking outcrops in this country have been found and investigated; but even so, there are undoubtedly some absolutely new districts to be discovered.

There are types of deposits which are not so readily recognized which may have been overlooked by earlier prospectors. For instance, there are the 'disseminated coppers' and certain types of low-grade gold deposits, the superficial indications of which are very slight. There are also the ores of the rare metals which are only known to a comparatively slight extent. Nor does the argument that a country is full of people necessarily prove that its mineral resources are entirely developed. The ignorance of men con-

cerning things outside their education or daily occupation is remarkable, and scientific curiosity is strikingly rare. I, when a child in Michigan, found a piece of galena in a sand bank and, carrying it back to the village, spent a half day trying to find some one who knew what it was. Finally the specimen was shelved and its identity determined only by chance some weeks later.

Is it likely that a quartz outcrop in Maine or Michigan would be sampled and assayed for gold? It might have been seen by scores of lumber-jacks, timber cruisers, and hunters without one of them thinking of such a thing as a metal-bearing vein. The comparatively recent discoveries in the Cobalt and Porcupine districts are evidence that fur traders, lumbermen, and sportsmen may know a region thoroughly and still leave it unprospected. The Michigan iron and copper deposits which attracted attention in the early '60s were striking in their outcrops; but in the case of the iron ranges the scientific exploration of later years has developed more iron ore than was ever dreamed of in the early days. In one of these districts I have seen a chain of useless swamps develop into the most valuable iron land in the county; old, tumble-down wooden shaft-houses on abandoned mines have given place to steel head-frames at which are motors driven by electricity derived from the trout stream that "wasn't any good after it had been logged." Still the Upper Peninsula of Michigan is almost a *terra incognita* after leaving the iron and copper deposits.

In my opinion, the most promising field for prospecting in the broader sense is that offered by the older mining districts. One has only to procure a copy of 'Western Mining Districts,' a U. S. Geological Survey publication, to have the question of where to look greatly simplified. Most of the localities throughout the West in which the conditions favor the formation of ore deposits are noted in that bulletin.

Next is the question of what to look for. The answers to this may be tabulated as follows:

1. Deposits of types not generally known, including ones of the rare metals.

2. Deposits of types probably unfamiliar to the laboring miners of the district.

3. Conditions favoring the occurrence of orebodies of the kind best known in the district which may have been overlooked in earlier mining operations. Under this head are orebodies having no outcrop, those that have been lost by faulting, and those not discovered because of the control of development work by some erroneous hypothesis or 'hunch.'

Two cases may be cited briefly here. In one instance a very productive vein was cut off by a fault, and the management spent many thousands of dollars endeavoring to find the lost portion. It was assumed that the fault was a single definite plane, along which only one movement had taken place; on the contrary, it is a wide crushed zone, and there have probably been several periods of movement. As a consequence

of misunderstanding the real conditions, the work done by the old company was not so directed as to solve the problem.

In another instance a company spent a great deal of money hunting for a 'quartzite foot' because the orebodies in the big mine of the district occurred above a bed of quartzite. There was no such formation on the company's ground. The outcrops that led to the staking of the claims were on or near a shale-limestone boundary, and the shales have formed a barrier to the mineral-bearing solutions, with the result that this boundary is a locus of ore deposition, though not uniformly mineralized either along its strike or vertically. Most of the work in this mine was done on the 'hunch' that the ore *must* have quartzite beneath it; to furnish this necessary geological condition, a band of silicified limestone some 600 ft. from the shale bed has been taken as the objective for a series of cross-cuts all leaving the locality of the only orebodies that were ever worked on the property, the proceeds from which very nearly paid for "the extensive development work to locate the quartzite." There is no doubt that many of these old mines in almost forgotten districts will amply repay the expense of careful investigation and well planned development work. But it is very difficult to interest capital in such work.

"We have sufficient funds to buy anything good, up into the millions, but we must know that it is good; it must be big, and fully developed. No, we do not think favorably of that district: it has been dead a long time. If there were anything there it would have been found years ago. I have a report in my files by Mr. Soandso, who spent three days there in 1900, and there is nothing there."

That is about the attitude of the men with money to play the mining game, and who complain that they can find no place to put it. As a matter of fact, we are just passing beyond the 'boom' days of the mining industry in this country. The days of 'easy money' are gone, and the future calls for hard, careful work on the part of the men who would find new mines. The engineer cannot run into a camp in the morning and leave the next day with a 'sure thing' in his pocket. He must know the district thoroughly, must know its details, and must look for the facts that are not obvious; he must "see into the ground further than anybody else," even at the risk of achieving the impossible. The men associated with him must uphold his decisions by taking reasonable chances, and they must develop mines instead of expecting them to turn out ready-made.

If honest, exhaustive examination work and a reasonable expenditure of money for development fail to discover new mines, then one might as well admit that the days of the industry are numbered, and go to farming. But not until more real looking has been done, both in the estimation of the possibilities of old properties and new prospects, and by breaking ground to prove or disprove them.

J. H. FARRELL.

Los Angeles, California, April 19.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Calcium carbide consumed at the Lonely Reef mine, Rhodesia, amounted to 3156 lb. in 1913.

Average cost of mining anthracite is about \$2.07 per ton, exclusive of charges for depreciation, amortization or interest. In 1913, the average price per gross ton was \$2.38.

Mine cave-ins have occurred from time to time in the town of Scranton, Pennsylvania, but have been exaggerated. To prevent further trouble, the coal mining companies are making an annual contribution for the permanent support of the surface.

High-frequency electric current, so-called 'diathermy,' is being used by Gustave Killian, of Berlin, in the treatment of cancer. The diathermy produces a coagulation of the tissues through which it is passed. In a lecture in London, he recently spoke on the palliative results of radium treatment of certain growths too advanced for radical surgical removal. During 1913, the Radium Institute of London treated 972 cases of cancer, including 490 cases of malignant disease of which 111 were of rodent ulcer. Of the malignant cases, none is stated to be actually cured, although 56 are described as 'apparently' and 183 as 'improved'. The medical superintendent, A. E. Hayward Pinch, said that the use of radium is not understood.

Death may occur from shock by the electric current either through temporarily paralyzing the nervous control of the muscles of respiration, or stopping the regular beat of the heart. When the heart is seriously affected it ceases to contract as a whole, but continues to contract in parts here and there, so that it appears to quiver. It is then said to 'fibrillate.' In this condition the heart fails to keep the blood circulating and death quickly results. At present no practical procedure has been discovered which will restore the regular beat of the heart in man after it begins fibrillating. Hope of resuscitation is now restricted to proper treatment of the cases of paralyzed respiration; and since deprivation of oxygen for about ten minutes injures irremediably some of the nerve centres of the brain, it is particularly important that measures for resuscitation be applied immediately and continued until natural breathing returns. In some instances, however, the heart may be merely weakened without being made to fibrillate; in such cases artificial respiration may be of vital importance, because a greatly weakened heart leads to impairment or total stoppage of respiration, which in turn destroys the last vestige of the heart-beat. In all cases, therefore, an attempt should

be made to restore natural breathing. Fortunately, artificial respiration can be applied by laymen without immediate need of complicated apparatus.

Alterations and additions to the Dome mill at Porcupine, Ontario, will result in the following plant, it having been decided in 1913 to convert the existing process of all-sliding to one of leaching sand and filtration of slime, according to the general superintendent, H. C. Meek. The ore, after being delivered from the rock-crusher station, is to be crushed by 80 stamps (40 added) and 5 tube-mills, the product from the tube-mills being then distributed over 24 amalgamating plates, on which over 50% of the gold will be recovered. The product is then to be classified into sand and slime by means of hydraulic classifying and concentrating cones. The sand will be delivered to six vats, each 40 ft. diameter by 8 ft. 6 in. deep, for leaching by cyanide solution. The slime will be treated in the existing plant of four 8 by 40-ft. Pachuca tanks, and three 30 four-inch frame Merrill slime presses. The gold will be precipitated in 52-in. Merrill zinc-dust presses as during the past. In addition to the above, improvements to the rock-crusher station and belt-conveying system to the mill for the increased tonnage are in progress; and the water supply pumping scheme from Porcupine Lake has been completed.

Dredge buckets have been increased in size, until the present largest of 16 cu. ft. capacity seems to be the economic limit. A bucket of this size weighs over two tons, and a digging ladder with 80 or 90 of these is

THREE SIZES OF DREDGE BUCKETS.

subjected to considerable strain, as is also the boat itself. The accompanying cut shows a comparison of sizes of the first dredge on the Yuba river, California; a 7-cu. ft. bucket of early boats; and a 15-cu. ft. bucket of Yuba No. 13.

Special Correspondence

LONDON

CONTROL OF PERSIAN OIL DEPOSITS ACQUIRED BY ENGLAND; AN
INSTANCE OF FAR-SIGHTED BRITISH STATESMANSHIP.—DE-
SCRIPTION OF THE DISTRICT.

Purchase of control of the Anglo-Persian Oil Co. by the British Government is an event of some importance in many ways. In the first place, it provides the first instance of the government obtaining for itself a source of supply of fuel of any kind for warships, having previously been at the mercy of the Welsh and English coal owners. Second, it proves to the 'man in the street' that oil is a much more important factor in the fuel problem than the average resident in the British Isles imagines. Third, that failing to obtain adequate supplies of oil within the British Empire, it has been necessary to go to a country within or near a hostile influence, that of Russia. It is opportune to say here that the oil required for British battleships is heavy oil suitable for combustion in steam-boiler furnaces, and not for internal-combustion engines. There are many advantages in burning oil fuel under steam boilers of warships, one being the absence of tell-tale smoke, and another the ease of equalizing the load in the ship, as the oil is consumed. As regards sources of supply, the attempts at securing a control of Mexican supplies were rendered futile by the revolutions, and a footing was not allowed in South America by representations relating to the Monroe Doctrine. The Persian deposits come very near the Russian horizon, and are also near the Turkish dominions where the Emperor Wilhelm of Germany likes to exercise a squeezing influence occasionally.

The history of the development of the Persian oil deposits is romantic. Fifteen years ago, W. K. D'Arcy, one of the men made rich by the Mount Morgan mine in Queensland, went in for oil, and obtained the sole prospector's license throughout Persia, with the exception of the northern provinces bordering on Russia. His first exploring parties met with modified success, and in the early years only one district, Kash-I-Shirin, in the northwest part, gave anything like promising results. But it was not until attention was turned to the bituminous seepages farther south, near Shushtar, that success was really attained. Here an oilfield of great potentialities has been developed, under the name of Maidan-I-Naphtun. The wells are about 1200 ft. deep, and the oil comes from a hard porous limestone of Miocene age. Other districts named White Springs and Ahwaz, nearby, are also being tested.

On the Maidan-I-Naphtun field, 30 wells have been drilled. Only 12, however, have been carried through to the oil horizon, and these have all produced oil; but some are wholly or partly shut-down, as their production is not at present required. There is storage available for 60,000 tons of crude oil, either in steel tanks or open reservoirs. The oil is conveyed by pipe-line to the refinery at Abadan near the Persian Gulf, distant about 145 miles, and about 800 ft. below the level of Maidan-I-Naphtun. The pumping station is situated at Tembl, $2\frac{1}{2}$ miles from the wells, where powerful modern pumping machinery has been installed. The pipe-line is 6 in. diameter as far as Wals (53 miles), and 8 in. thence to Abadan, and has an estimated capacity of about 1000 tons per day, though this figure has been appreciably exceeded for short periods. The greater size of the pipe-line from Wals will enable considerable quantities of oil to be carried from the White Springs and Ahwaz, if the borings there are successful, without reducing the quantity being carried from Maidan-I-Naphtun. The pipe-line is provided

with gate-valves 10 miles apart, and stations have been placed at intervals of 20 miles for the purpose of keeping an hourly record of the pressure, so as to detect and avoid any loss by leakage.

The refinery is of modern construction, and laid out with a view to future extensions. It contains four benches, consisting in all of 34 stills, and petrol, kerosene of two qualities, and oil-fuel are produced. To prepare an oil-fuel suitable for admiralty requirements, it is only necessary to remove about 30% of the light products; allowing 5% for loss in refining, a quantity of oil-fuel is obtainable equivalent to 65% of the original crude. A bench of four stills is capable of treating 7500 tons of crude oil, giving an output of about 4800 tons of admiralty fuel per month; and as the refinery is at present constructed, 20 stills could be turned on for this purpose which would produce about 24,000 tons per month, or say about 280,000 tons per year. The total capacity of the pipe-line is not sufficient, however, at present to deliver the necessary amount of crude oil, and the maximum possible output of oil-fuel at the present time cannot be estimated at more than 20,000 pounds per month. The total storage at the refinery, completed or under construction, will have a capacity of nearly 110,000 tons, of which 60,000 tons will be for crude oil. A steel pier has been built on the river bank near the refinery, having a depth of 25 ft. of water alongside at low-water spring-tide, but tank steamers load to only 18 ft. 6 in. at the pier, and take the remainder of their cargo from lighters below the bar. It is expected that it will eventually be possible for vessels to load to a greater depth at the refinery.

NEW YORK

EXPERIMENTS ON KEYSTONE, ARIZONA, COPPER ORE.—EAST BUTTE
MINE.—BRADEN MINE AND PLANT.—MOND NICKEL CO.—
GUANAJUATO REDUCTION & MINES CO.—COMPANIA HUAN-
CHACA DES BOLIVIA.—DEVELOPMENT COMPANY OF AMERICA.

The new Keystone Copper Co. has made its report for the year ended December 31, 1913. The assets of the Company were valued at \$1,455,000, and the report shows cash on hand of \$3641. An interesting feature of the report is the account by J. P. Channing of the results of experiments made by R. C. Canby on the treatment of the ore. The first plan was to crush the ore fine, leach the oxidized copper minerals, and recover the sulphides by concentration. Experiments showed, however, that much of the chalcocite was in coarse form, while much of the oxidized material consisted of cuprite which is almost insoluble in sulphuric acid. Experiments are now being made along lines of giving the ore a light roast to make the cuprite soluble, at the same time oxidizing the sulphides. Flotation is also being considered. As the Company has blocked out 2,500,000 tons of ore which averages about $2\frac{1}{4}$ % copper, the treatment of the ore is of great importance. An experimental mill has been built near Miami, and experiments are still under way. The Company is in litigation with the Inspiration Consolidated, which is seeking to obtain an underground right-of-way through Keystone ground. The preliminary injunction granted last year to the Keystone has been made permanent, and the Inspiration has started condemnation proceedings against the Keystone to secure the desired right-of-way. The case is now before the Supreme Court of Arizona, and it is not known when the decision will be handed down.

The East Butte company is doing well under the capable management of Oscar Rohn, and will probably turn out over 1,250,000 lb. of copper monthly during this year, most of it from its own ores. The East Butte has been smelting Davis-Daly ores, which are decreasing in amount. The East Butte is a most interesting example of how a mine can 'come back,' as after having been a failure it has developed into a suc-

Utah. Under the former Company the mineralized area was estimated at about half the value of the total property owned. The tunnel furnished water and transportation for several Bingham companies. One of the main objects was to haul waste from Bingham, where there is a lack of dumping room, to Tooele, where the waste can be used to advantage. E. P. Jennings succeeded Walter B. Farmer as president, director, and executive officer of the old Company.

Contrary to tradition, there seems to be a chance of another copper mine being developed at Jerome, Arizona, on the side of the holdings of the United Verde of W. A. C. Interests closely affiliated with Phelps, Dodge & Co. are conducting comprehensive exploration and development on the United Verde Extension, and results have lately been reported as encouraging, indicating that profitable ore will be exposed in the near future. United Verde Extension has never done much in a market way. The Company's mineralized holdings in area exceed those of the United Verde.

The Anaconda Copper company, through a subsidiary company called the Deer Lodge Valley Farms Co., is offering, on easy terms, 10-acre farms in the town of Opportunity, lying between Anaconda and Butte. These lots are situated in the Deer Lodge valley, where the farmers several years ago bought the Anaconda interests on the ground that fumes from the Washoe smelter was destroying their crops and vegetation. Your correspondent traveled last July through the area which was under contest between the smelting and farming interests, and was surprised to note the strength of the crop and forest growth. It is claimed that the sulphur which escapes from the smelter stacks, in time as it settles down becomes an enriching element to the soil, and farmers are benefited rather than injured by it. At any rate, the Anaconda company has been experimenting, and proposes to encourage intensive truck farming right under the shadow of the Washoe smelter. The Company will also become a large manufacturer of sulphuric acid for use in its own leaching processes and for sale in Butte, which has in the past year become a large consumer of acid, and which it buys in Denver at \$22 per ton.

A recrudescence of the Old Dominion suit against A. S. Bigelow has resulted in another decision favoring the Company. At first it was thought that this would lead to a distribution of the bulk of the assets awarded the holders of Old Dominion 'trust receipts' as made by the Supreme Court two years ago. A dividend of \$10 per share was looked for. But here is to be deferred again. G. F. Hyams, an associate of Mr. Bigelow, succeeded in tying up the matter for two years by securing an injunction restraining the distribution of the assets placed with a trust company by Mr. Bigelow to secure payment in the event of judgment against him, and it seems that Mr. Hyams has one or two more 'tricks' up his sleeve. The liquidating value of the 'trust receipts' will be about \$12 or \$13 per share, but they are selling at a price on the Curb here, and are inactive at that. This shows clearly that the average trader in the stock market is willing to gamble on nothing less than the forthright decision of a court.

Thanks to the efforts of one Boston banking house, the Boston mining list has been 'liberalized,' and when the copper was not becalmed as at present, attention is somewhat diverted to zinc, gold, and coal issues. Alaska Gold, Butte & Superior, and the 'coal-dust twins,' Island Creek and Pond Creek, have recently by their activity or price strength contributed no little to taking investors' minds off of the heaviness of the red-metal issues. Copper stocks in Boston since the first of June have been exceedingly quiet. The extreme variation of 20 active coppers has been less than a point, showing a deadlocked market.

The demand for copper has been slight of late and but few sales are reported. The foreign demand has declined considerably and is again about normal. European consumption continues heavy.

WASHINGTON, D. C.

SAFETY INVESTIGATIONS OF THE PHOENIX COPPER MINES.

APPROPRIATIONS ASKED.—EXPLOSIVES IN MINES.—PICTURES IN EDUCATIONAL WORK.

THE PHOENIX COPPER MINES IS TO HAVE AN APPROPRIATION OF \$100,000 THIS YEAR FOR SCIENTIFIC INVESTIGATIONS CONCERNING THE MINING, PREPARATION, TREATMENT, AND UTILIZATION OF DYES AND OTHER MINERAL SUBSTANCES, WITH A VIEW TO IMPROVING HEALTH CONDITIONS, INCREASING SAFETY, EFFICIENCY, AND ECONOMIC DEVELOPMENT, AND CONSERVING RESOURCES THROUGH THE PREVENTION OF WASTE IN THE MINING, QUARRYING, METALLURGICAL, AND OTHER MINERAL INDUSTRIES. MORE PARTICULARLY, THE MONEY IS TO BE USED IN CONNECTION WITH THE STUDY OF THE WASTE AND DESTRUCTION OF PRODUCTS FROM SMELTERS, ESPECIALLY COPPER SMELTERS, AND THE GENERAL DAMAGE TO THE COMMUNITY ARISING FROM SMELTER FUMES.

In asking for the appropriation, the director, E. A. Holmes, told the House Committee on Appropriations that the gases contained chiefly sulphur and arsenic, other substances being given off in much smaller quantities. And, as to the amount of gases given off, he said, might be gained from the fact that one smelter in Montana gives off 1000 tons of sulphur per day. The damage here extends for miles beyond. Added Mr. Holmes, in the case of another smelter, in California, the damage can be traced 25 miles where the drift of the wind is constant for a considerable period, and the area is extensive. A VIEW AS TO HOW TO TAKE CARE OF ARSENIC AND THE METALLIFEROUS MATERIALS GIVEN OFF IN SMALL QUANTITIES SUCH AS LEAD FUMES, AND THAT PART OF THE SULPHUR GIVEN OFF IN THE FORM OF SULPHURIC ACID, THE SO₂ COMBINATION WHICH GOES INTO SULPHURIC ACID AND WHICH IN THAT FORM IS DECIDEDLY INJURIOUS. ABOUT THE SMELTER ITSELF, WHERE THE EMPLOYEES OF THE COMPANY OPERATE, MOST OF THE DAMAGE DONE HAS BEEN FROM THE LEAD AND ARSENIC. THE POLICY THAT WE HAVE FOLLOWED IS THAT, WHEREVER FEASIBLE, INVESTIGATIONS WHICH ARE LOCAL IN THEIR CHARACTER MUST BE PAID FOR BY THE COMPANIES THEMSELVES RATHER THAN BY THE GOVERNMENT. IN CONNECTION WITH THE SMELTER INVESTIGATIONS, HOWEVER, THERE WERE CERTAIN PROBLEMS WHICH THE SMELTER COMPANIES HAVE PRACTICALLY DECLARED TO BE UNSOLVABLE, AND THEY DID NOT THINK THEY OUGHT TO BE CALLED UPON TO SPEND MONEY TO SOLVE, BECAUSE THEY DID NOT THINK THEY COULD BE SOLVED, AND THE RESULTS WOULD APPLY TO OTHER SMELTERS AS WELL AS THEMSELVES. OF THE APPROPRIATION LAST YEAR FOR THIS GENERAL WORK, \$15,000 WAS EXPENDED FOR SMELTER WORK. WHEREVER THE PROBLEM WAS AT ALL A LOCAL ONE, WE HAVE REQUIRED THE SMELTING COMPANY TO DO THE INVESTIGATION. WE SELECTED THE MEN AND WE MAPPED OUT THE LINE OF EXAMINATION, BUT EVERY DOLLAR OF EXPENDITURE AND THE EMPLOYMENT OF THE MEN AND THE HANDLING OF THE MONIES HAS BEEN ENTIRELY WITHIN THE HANDS OF THE SMELTING COMPANIES. WITH THE EXPENDITURE OF \$15,000, WE HAVE THIS YEAR CONDUCTED THE MORE ABSTRACT OF THE INVESTIGATIONS, WHICH COULD NOT BE CONSIDERED LOCAL IN THEIR CHARACTER. THREE OF THE SMELTERS, UNDER OUR GENERAL ADVICE, ARE CONDUCTING INVESTIGATIONS, EACH ONE OF WHICH COSTS PRACTICALLY AS MUCH AS THE AMOUNT WE ARE SPENDING. IT SEEMS OUR DUTY TO GET OTHER PEOPLE TO BEAR THESE BURDENS JUST AS FAR AS FEASIBLE. WE HANDLE NONE OF THE MONEY OF THESE SMELTING COMPANIES; WE PLAN THE INVESTIGATIONS AND SELECT THE MEN TO DO THE WORK, AND WATCH THE RESULTS.

Mr. Holmes was asked by members of the committee about the waste of sulphuric acid. "Unless there is a market for the sulphuric acid, there would be the question of storage, and it would be leaking into the streams, which would be just as vigorously opposed as turning the gas loose in the atmosphere. What we are trying to do is to find some means of collecting the sulphur in the form of a solid, so that it can be compressed into cakes, then it can be stored without any difficulty or loss in storage. Sulphuric acid is used in a good many manufacturing operations in the East, but the supply comes from Louisiana or abroad because the cost of

transportation from the West is prohibitive. Nevertheless, we are trying to get some of the larger smelting companies to go into not only the manufacture of sulphuric acid, but also of the phosphates."

Mr. Holmes mentioned other lines of investigation, such as safety and waste investigations in certain metallurgical plants, like those for the extraction of silver and gold. He asked for an additional appropriation of \$20,000 for the next year. It is especially desired to use this money, he explained, with reference to investigating the explosives used in metal mining and quarrying. "In metal mining," he said, "they want quick action, because they want to shatter the rock, but they do not care anything about low temperature. What they want is an explosive that will produce the minimum of poisonous gases, because in metal mining there is no such extensive ventilation system as in coal mines." To instruct the men in the use of explosives, pictures were being used, he told the committee, because most of the men did not understand English. With each picture is a line or two in four different languages. "By that means we get them to understand the meaning of these lectures," he said, "and we have been quite successful in bringing out the entire attendance of the miners. They will come to see the pictures and then try to learn all about safety projects. We would be still more effective if we could afford to use moving pictures."

ROCHESTER, NEVADA

THE FEDERAL DREDGE.—BONANZA KING TO BE REOPENED.—4J LEASE DEVELOPMENT.—ROCK, SHEA AND COLLIGAN, AND FERRY-SAMPSON LEASES.—ROCHESTER MINES COMPANY.

The dredge of the Federal Dredging Co., operating a few miles northeast from Rochester in Spring valley, was sunk during the past week, a small hole having been punched in the bottom by a 'reef' or point of bedrock at a time when the water was low in the pond. This dredge has had a rather checkered career. It was built in the upper portion of the basin, where it was found after the starting of operations that the bedrock was very close to the surface, and 'reefs' of the same, over which it was impossible to float the dredge, were numerous. The dredge was then moved, after several attempts, overland, to the lower portion of the area, where conditions more suitable to successful dredging were found. It has been running a number of months with good returns. The pond has been drained, and examination has shown that the damage to the dredge is slight, and it will be in operation again within a week.

The Bonanza King mine was visited last week by one of the officials, and it was stated that this property would be unwatered and examined with a view to a resumption of operations.

On the Rochester Mines Co.'s property the 4J lease has cut 30 in. of ore assaying \$30 per ton, in a raise from the main level. It is thought that this ore is a continuation of the shoot exposed in the north end of the Codd lease. The 4J lease has driven 250 ft. in a cross-cut, easterly from the main drift, and has cut several small stringers. This work is being continued with the expectation of cutting the main east vein at this depth. Little work has been done on this vein, and only on the surface, but this was sufficient to show its milling value. It is possible that the main lessees, three in number, and those adjoining, will combine and operate under one management.

The Rock lease, on the Nenzel Crown Point property, has added another shift, and is driving a cross-cut to meet the drift from the bottom of the shaft. This will save hoisting, which has been necessary heretofore. A small shipment is being made from this lease.

On the Rochester Weaver Co.'s claims, the Shea and Colligan leases are extracting ore for shipment. The Ferry-

Sampson lease is also making a shipment. The main leases have continued to make shipments totaling nearly 100 tons per day.

A meeting of the board of directors of the Rochester Mines Co. is scheduled for Monday, June 15, and it is expected that Joseph F. Nenzel will resign as president of the Company, and that John Cowan, of Salt Lake City, will be elected to the place. Several directors are also expected to resign, and their places will be filled from the new management. J. F. Nenzel and Rudolph Nenzel are to remain on the board of directors. This follows the recent settlement of the litigation involving the controlling stock in this Company. It is rumored that various properties will be consolidated and that a mill will be built to treat the ores of this camp.

PLATTEVILLE, WISCONSIN

CONDITION OF ZINC-MINING INDUSTRY.—PRODUCTION OF DISTRICTS.—SMELTER BUYING.—AMERICAN METALS CO. AS A BUYER.—NEW PLANTS.—IDLE MINES, ETC.

The general depression affecting the zinc-mining industry seems to have had no deterrent effect, as far as zinc-ore production in southwest Wisconsin is concerned. The month of May shows the southern districts of the field to have been unusually active, and both production and shipments reached the highest point known for the field in the past two years, while a careful survey of reserve tonnage in bin at the close of the month shows over 6000 tons of concentrate held in bin in anticipation of better markets. Producers claim that zinc ore must be on a basis of \$40 per ton assay of 60% zinc to afford any profit to them, and yet the creditable showing made was accomplished on a market that held most of the month under this point. The higher grade separator zinc ore and high-grade wet concentrate were in fair demand, while the inferior grades suffered by comparison. Buyers showed no anxiety to circulate through the field and submit bids, and therefore the bulk of the output, both contract and open market offerings, was secured by the Mineral Point Zinc Co. Average prices prevailing for the month were reported by one of the leading ore buyers as follows: 30%, \$14; 35%, \$16.50; 40%, \$19; 45%, \$22.50; 50%, \$26; 55%, \$30 to \$32; and 60%, \$36 to \$39 per ton. Producers of carbonate zinc ore were afforded no market at all, although market quotations showed substantial improvement. Production was maintained in the face of this rather discouraging situation, and a large tonnage is ready for immediate delivery should the opportunity present itself. Lead ore was in poor demand, and the few sales reported cleared on bids of \$45 to \$46 per ton of 80% lead. The market on pyrite was off all the month, and the deliveries were less than half usually reported.

Deliveries were made during the month by districts as shown in this following table:

| District | Zinc, pounds. | Lead, pounds. | Pyrite, pounds. |
|-----------------------------|-------------------|----------------|------------------|
| Benton | 7,306,000 | 167,040 | 3,349,600 |
| Galena | 5,560,000 | | |
| Hazel Green | 3,514,000 | | |
| Livingston | 3,292,000 | | |
| Cuba | 1,922,000 | | |
| Linden | 1,152,000 | 194,370 | 60,000 |
| Harker | 1,080,000 | | |
| Platteville | 860,000 | 65,300 | |
| Shullsburg | 434,000 | | |
| Montfort | 242,000 | 50,000 | |
| Mineral Point | 172,000 | | |
| Highland | 132,000 | | |
| Dodgeville | 86,000 | | |
| Mineral Point Zinc Co. | 4,020,700 | | |
| Total | 29,772,700 | 476,730 | 3,409,600 |

Sales were distributed among the smelters as follows: to Mineral Point Zinc Co., 7054 tons; National Separating Co., Cuba, 1280 tons; Empire Roasters, Platteville, 1042 tons; Illinois Zinc Co., 820 tons; Grasselli Chemical Co., 739 tons; M. & H. Zinc Co., 515 tons; Wisconsin Zinc Co., Cuba works, 497 tons; Linden Zinc Co., 388 tons; American Metals Co., 346 tons; and Wisconsin Separating Co., 186 tons; a total of 329 cars, equal to 12,867 tons.

The American Metals Co. started buying for the first time as a competitive element. The Wisconsin Zinc Co. purchased the Campbell Magnetic Ore Separating Works, at Cuba, originally owned by J. B. Worthington and other Boston interests. The plant was overhauled and re-rigged, and began operating for the Wisconsin Zinc Co. on June 1. A decided increase in deliveries of high-grade ore out of the field will follow as a consequence of this transaction. The Galena Iron Works Co., founders and mill builders, was taken over by a new corporation capitalized at \$60,000. Prospect work with drilling machines received such impetus during the month that small operating concerns were unable to secure service. The vast holdings of the New Jersey Zinc Co., in this field, were personally inspected by 50 of the leading officials of the corporation during the month, and it developed later that a most elaborate mining program is to be started as a result of this inspection. New modern power and concentrating plants were completed during the month for the West Hill Mining Co., Platteville; Lawrence Mining Co., Hazel Green; and Unity Mining Co., Galena. New plants are in process of construction for the New Jersey Zinc Co., Benton; Wisconsin Zinc Co., New Diggings; and Frontier Mining Co., Benton. Agents of Boston and Philadelphia capitalists were quietly engaged in securing options and leaseholds in the Benton, Hazel Green, and Galena districts.

The Empire Roasters, at Platteville, after several years steady treatment of high-grade zinc ore, will be removed to the Wisconsin Zinc Co.'s new properties in the New Diggings district. Thirty-five mines, fully equipped with power and concentrating plants, were idle at the close of the month. Two particularly heavy zinc ore producers, the Vinegar Hill mine, in the Galena district, and the Ellsworth mine, in the Mifflin district, are exhausted, and will be abandoned and the equipment removed to more desirable points. The Mineral Point Public Service Co., furnishing electric power, is extending its line northward to include all of the northern mining districts. Exceedingly rich strikes of zinc ore were made during the month in the Benton, Linden and New Diggings camps. A boycott directed against the Northwestern Railway Co. has been put into effect by the leading mining companies in the Benton, New Diggings and Shullsburg districts, and the traffic diverted to the Illinois Central Railway. Three camps for years steady ore producers are flat at the present time, Highland, Platteville, and Shullsburg.

MELBOURNE, AUSTRALIA

MINING LEGISLATION.—A CURT REQUEST.—THE TASMANIA MINE.

A CONDEMNATORY REPORT.—GOLD AND SILVER IN 1913.

Attention is drawn by the *Australian Mining Standard* to examples of poor legislation by Australian governments. In Tasmania, a machinery act was rushed through parliament toward the close of last year. A clause in this measure made it obligatory for every motor in use below ground to have some one in attendance upon it continually. Not only so, but he must be a man properly qualified. The only mine to which the clause applies is the Mt. Lyell, and its underground pumps are electrically driven, and are started and stopped automatically. All that they require is occasional lubrication, so that all the attendant (who has, by law, to receive the wage given skilled labor) has to do is to sit and read or do anything else he can find to do to pass away

the time. The plants, it may be mentioned, are housed in chambers of iron and concrete, which are absolutely fire-proof.

Another instance given by this contemporary has reference to the Holman hoist. The mining laws of more than one of the states require the working of these little winches by certificated engine-drivers, though the skill required for their manipulation is no greater than that necessary for the working of a machine drill. What is the result? The practical abolition of the Holman hoist, because its use for the ordinary purpose of hoisting material from winzes becomes too expensive, as a man cannot be kept fully employed driving one, and the certificated driver will not (and indeed dare not) take on miner's work between hoists. So, instead of being benefited, the miner is handicapped by having to haul out his dirt by the slower and more laborious windlass. This is only one of many instances in Australian mining legislation of the authorities interfering to make the industry unremunerative.

Surely the funniest thing that has yet happened in any strike in any part of the world has occurred at Lithgow, New South Wales. The 'fillers' at the Invincible colliery struck for an increase of wages. In the ordinary course of things this meant their earning nothing during the progress of the strike and being dependent upon payment from the union to which they belonged; but this was something not at all to their taste, so they hit upon the happy idea of asking the manager to find them other work during the continuance of the strike. For sheer impudence, this is hard to beat.

As was only to be expected, the report of the independent engineers, W. H. Cundy and J. Fawcett, appointed by the late Tasmanian government to make an inspection of the Tasmanian gold mine, Beaconsfield, has entirely confirmed the reports on which the directors were acting when they resolved to close down the mine. The summary and conclusion of the report are sufficient indication of the position taken by the engineers. It is as follows: "The mine is practically worked out down to 1500 ft. There have been blocks of good grade ore down to the 1500-ft. level, but as stoped in bulk and sent to the mill has been unprofitable. The lode is going down strong, but there is no evidence on which to found any expectation of increased gold content at the next or lower levels, though there is always a possibility of that happening. On that possibility, and if we were reporting for shareholders, we would not recommend the expenditure of £50,000 to £60,000 to sink the shaft and develop another level."

The gold output of Australasia in 1913 was as follows:

| | Fine oz. |
|--------------------------|-----------|
| New South Wales | 149,657 |
| Victoria | 434,932 |
| Queensland | 265,735 |
| South Australia | 6,545 |
| Western Australia | 1,314,048 |
| Tasmania | 33,400 |
| Northern Territory | 3,119 |

| | |
|--------------------------|-----------|
| Total Australia | 2,307,436 |
| New Zealand | 343,627 |
| Papua (New Guinea) | 15,094 |

Total Australasia

The silver output of Australasia in 1913 was as follows: New South Wales, 5,908,638 oz., and 8,596,251 oz. in concentrate, a total of 14,504,889 oz. fine, valued at £1,757,963; Queensland, 604,979 oz., valued at £68,438; Tasmania, value of silver-lead production, £319,997; South Australia, value of silver-lead production, £1100; Western Australia, value of silver exported, £20,376, and value of silver-lead exported, £53,524; and New Zealand silver export, 975,591 oz., valued at £103,862.

General Mining News

ALASKA

FAIRBANKS

Careful estimates of the gold production of this district for the current season show a total of \$3,791,000, or about the same as last year. The various creeks should yield \$2,911,000; Hot Springs about \$700,000; and the Tenderfoot, Kantishna, Bonanza, and outlying districts about \$180,000. Dumps on the creeks contain about \$665,500. The order of output from creeks is estimated as \$503,000 from Charanika, \$438,000 from Ester, \$329,000 from Creary, and \$312,000 from Goldstream. No estimate of the yield from the quartz mines has been made.

May returns of the mines on Douglas island were as follows:

| | Alaska | Alaska | Alaska |
|---------------------------|----------|-----------|----------|
| | Mexican | Treadwell | United |
| Development done, feet | 30 | 329 | 1,161 |
| Stock of broken ore, tons | 1,418 | 66,973 | 8,651 |
| Stamps working | 120 | 540 | 240 |
| Ore crushed, tons | 20,811 | \$3,706 | 40,796 |
| Concentrate saved, tons | 355 | 1,566 | 900 |
| Gold by amalgamation | \$20,062 | \$101,517 | \$44,493 |
| Gold by cyanidation | 20,269 | 89,660 | 40,447 |
| Average per ton | 1.94 | 2.28 | 2.10 |
| Net profit | \$16,363 | \$100,866 | \$28,655 |

Of the development done in the Alaska United company's 700-Ft. Claim mine, 345 ft. was performed on the 1570 and 1750-ft. levels by the Alaska Treadwell company. No steam power was necessary during the month, water being plentiful. A bonus dividend, No. 107, of 75c. per share, will be paid by the Alaska Treadwell Gold Mining Co. on June 29.

A gold nugget worth over \$2600 was found on ground worked by W. Redwood and associates on the Hammond river in the Koyukuk district. They also got smaller nuggets worth a total of \$1000. The largest nugget found in Alaska, on Anvil Creek, Nome district, was worth \$3200.

ARIZONA

GILA COUNTY

At the Barney Copper Co.'s mine, 25 men are employed. The shaft is down 125 ft., and over 100 ft. per month is to be sunk. At a depth of 312 ft. in the Inspiration Extension, adjoining the Keystone, Inspiration, and Live Oak properties, copper ore similar to that from the Scorpion shaft of the Inspiration has been cut. The shaft is to be sunk to 500 ft. The Gibson mine is employing 20 men and shipping about 100 tons of 30% and 200 tons of 14% copper ore per month to the Old Dominion smelter. Tests on the ore are being made in San Francisco.

PINAL COUNTY

(Special Correspondence.)—Electric power transmission lines are now connected with the Magna mine at Superior. The new mill probably will be ready by July 1. The Silver King mine has been bonded to an English syndicate. The Ajax claims, near the Reymert mine, has been taken over by George N. Bience, who represents Seeley W. Mudd. The price was \$50,000. Superior, June 18.

YAVAPAI COUNTY

(Special Correspondence.)—The Emporia camp on Groom creek is quite busy. More men are to be employed at the Emporia mine and ore is to be sent to Douglas in July. Emporia, June 18.

CALIFORNIA

NEVADA COUNTY

A sum of \$35,000 is to be spent at the Golden Center Valley mine in erecting a 60-ft. head-frame, sinking a new shaft, and installing an electric hoist. The 10-stamp mill is working continuously. C. A. Brockington is superintendent.

PLACER COUNTY

The old Mayflower mine, on the Blue lead, is being reopened in charge of Charles Akers, formerly of the Hidden Treasure. The Gray Eagle, another old mine, is being reopened. A number of claims in the Forest Hill district are being prospected.

Twenty men are working for the Excelsior Consolidated Gold Mining Co. at Cisco.

PLUMAS COUNTY

Keisler, used in the manufacture of explosives and other materials, has been identified in the Golden Eagle and Goodenough mines, near La Porte. The mineral has been mined here since operations started, but, its value not being known, was discarded as waste.

SIERRA COUNTY

A good deal of prospecting is being done in the American Hill district, where a number of claims show promising results. An electric pump is now working in the Kate Hardy mine, near Forest, and sinking has been resumed. A. D. Grum is in charge. The interior shaft of the North Fork mine is down 75 ft., and is to be continued to 200 ft. before crosscutting. The Miners' Home gravel mine has changed hands, and 25 men are being employed by W. Spencer. The deposit is really stiff pipe-clay mixed with boulders. In washing, it is dumped into a hopper filled with water, and when the clay gets soft the pulp is run through a sluice-box in the usual way. Average returns are \$10 per carload. Good gravel has been opened in the Motor claim at Port Wine.

SISKIYOU COUNTY

Charles T. Harbeck, a New York capitalist and president of the Siskiyou Mines Co., operating a large hydraulic mine

MAP OF TRINITY COUNTY

6 miles above Happy Camp, has just completed his annual 10-day inspection of the property. Mr. Harbeck was satisfied with the progress being made and the general condition of the extensive property.

TRINITY COUNTY

The claim held by John Hays Hammond and associates

on over seven miles of placer ground along the Trinity river has been extended, and further prospecting is being done. Sufficient ground has been already proved to warrant the building of dredges.

TUOLUMNE COUNTY

The Rawhide mine, three miles north of Jamestown, is being unwatered prior to examination. The App-Heslep claims at Quartz may also be mined.

COLORADO

GILPIN COUNTY

A lease and bond has been taken on the Keystone claims, in Quartz valley, by T. R. Cudahy. Past production is over \$200,000. Ore-shoots at 900 and 1000 ft. in the Pittsburg mine, in lower Russell gulch, are developing well. The mine produces 90,000 gal. of water per day. Recent shipments are as follows:

| | No. 1. | No. 2. | No. 3. |
|------------------------|--------|--------|--------|
| Tons | 17 | 17 | 16 |
| Gold, ounces | 4.17 | 4.66 | 6.21 |
| Silver, ounces | 5.26 | 6.20 | 6.40 |
| Copper, per cent | 5.85 | 6.20 | 6.14 |

Kramer Bros., H. Wherry, Holmes & Co., and the Bates Leasing Co. are all doing well with their leases.

TELLER COUNTY (CRIPPLE CREEK)

Four distinct shoots have been partly developed at 1600 ft. in the Vindicator mine. There are 125 miners employed on No. 11, 12, 13, 14, and 16 levels. Lessees are working on levels above and on shafts No. 2, 5, 6, and 11, and the Hull City shaft. Good progress is being made with the new concentrating plant. H. P. Nagle, Jr., is superintendent. Unworked ground on Battle mountain, owned by the United Gold Mines Co., is to be worked by lessees.

IDAHO

BLAINE COUNTY

The mill of the Wilbert mine, 40 miles from Arco, is to be restarted in a few days, according to the manager, Harry S. Knight. Steady development was carried on while the plant was stopped, and 75 tons of lead ore per day can be supplied.

CUSTER COUNTY

Rich gold ore is reported to have been discovered by W. Oster and the Wells brothers at the old Montana mine on Estes mountain. Little has been done on this property for many years. A few men are now working at the old Ramshorn mine at Bayhorse, which has been practically idle for about 20 years. Past work consisted in driving 15 adits and connections a total of about seven or eight miles, and a production of copper-silver ore worth \$3,000,000.

SHOSHONE COUNTY

Work has been resumed at the Morning mine by the Federal company, which was shut down several weeks ago. Good lead-copper-silver ore was opened in the Great Western mine some time ago, and sinking on the shoot is to be started. The claim is above Burke. Rich silver ore has been opened in the Hughes lease of the Yankee Boy mine near Wardner. During the quarter ended May 30, the Federal Mining & Smelting Co.'s net earnings were \$218,456, of which \$180,000 was paid in dividends. The surplus on June 1 was \$1,540,187.

F. Augustus Heinze and his associates have lost their suit to oust McKinnon & Carrington of the Assets Realization Co. from the directorate of the Stewart Mining Company.

MICHIGAN

HOUGHTON COUNTY

The worst air-blast in the history of the Quinex mine occurred last week. Work at No. 2 shaft can be resumed in about three weeks.

MISSOURI

JASPER COUNTY

Just above water-level, at 216 ft., the M. & N. Mining Co. is mining 25% 'jack' ore south of Carterville. The operators state that good ore is opened to 230 ft., and again at 245 ft. Heavy timbering is necessary in the soft ground. A 4-in. motor-driven centrifugal pump is draining 12 acres of Connor land, south of Carterville, leased by F. Wallower. Previous work was done from 190 to 215 ft. depth. At 60 ft., in a lease of G. L. Childress and B. Messenger, lead and calamine ore yielding nearly 75% is being mined.

MONTANA

JEFFERSON COUNTY

The Whitehall Mining, Milling & Development Co. has been organized at Whitehall, with a capital of 500,000 \$1 shares. Of these, 50,000 were subscribed for, 200,000 are in the treasury, and 250,000 were given for the Burlington group of mining claims. These claims are three miles northeast of the town. Over 200 ft. has been driven on a 36-ft. ore-body. Ore shipped has assayed up to \$32 per ton, but average assays are \$16.50 per ton. Officers of the Company are: T. T. Gates, president; N. D. Root, vice-president; and C. W. Hatch, secretary. These are directors with Edward Ryan, Jess Johnson, L. B. Knight, Ross Edwards, J. M. Borden, and James Ryan.

SILVERBOW COUNTY

The report of the Anaconda Copper Mining Co. to the assessor of this county for purposes of taxation for the twelve months ended June 1, 1914, shows net earnings of \$8,613,564, against \$11,446,901 last year. Net earnings for the calendar year 1913, as shown by the annual report to stockholders and review in this journal of May 22, were \$11,323,498. The latest statement is as follows:

| | 1913-14. | 1912-13. |
|------------------------------|--------------|--------------|
| Ore mined, tons | 4,714,653 | 4,531,640 |
| Gross revenue | \$39,464,004 | \$35,471,733 |
| Yield, per ton | 8.37 | 7.81 |
| Total mining cost | 17,816,505 | 18,285,415 |
| Cost per ton | 3.78 | 4.03 |
| Cost of transportation | 1,405,538 | 1,369,843 |
| Cost of treatment | 8,055,694 | 8,496,850 |
| Cost per ton | 1.71 | 1.87 |
| Cost of marketing | 3,570,478 | 3,531,602 |
| Total costs | 30,850,439 | 31,683,812 |
| Net proceeds | 8,613,564 | 11,446,901 |

The lower price received for copper partly explains the reduced profits for the period just ended. As the Company has 1,332,500 shares outstanding, exclusive of 330,000 shares to issue for the International Smelting & Refining Co., the net profits for the year ended June 1 were equal to \$1.99 per share, against \$3 paid in dividends. In other words, the Company fell \$4,350,000 short of earnings dividend requirements for this period.

Suit has been started at Helena by minority stockholders of the Alice Gold & Silver Mining Co. against the Anaconda Copper Mining Co. and majority stockholders of the Alice Gold & Silver company, involving property alleged to be worth several million dollars, and in which the Sherman anti-trust law is invoked. The plaintiffs allege that on May 27, 1910, the majority stockholders of the Alice company voted to transfer the stock of that company to the Anaconda company, and that the stock so voted was worth \$1,000,000, while the 30,000 shares of stock received from the Anaconda company were worth only \$1,020,000. The plaintiffs allege that this really amounts to restraint of trade, and in support of that contention they recite the history of the Amalgamated Copper Co. since 1899, tending to show that that company, which controls the Anaconda, continuously has been buying up min-

ing properties in Silverbow county and paying them with their own stock.

An independent miners' union was formed at Butte on June 21 in spite of overtures from Charles H. Moyer and other Western Federation officials. W. McDonald is temporary president, and most of the executive committee are I. W. W. men. A mass-meeting of 5000 men was held, voting being done by acclamation. An assessment of 50c. per month is to be levied.

Further trouble arose at Butte on June 23, when a meeting was to be held at the Miners' Union hall to hear a 'peace' plan by Charles H. Moyer. A crowd threatened to break up the meeting and sheriff's deputies opened fire on the men, killing one and wounding several others at the same time. Three charges of dynamite wrecked the front of the hall. Moyer has promised a full investigation into the old union's affairs, but in the meantime has fled.

NEVADA

During the ten months that the Nevada Industrial Insurance Commission has been in existence, a total of \$203,211 has been paid in as premiums by the various industries allied with the Commission. Of this total, \$167,627, or 82%, was contributed by the mines of the state. In the mining,

milling, and smelting industries, 257 firms, corporations, and individuals are contributors to the fund and employ 7710 men. Some of these are as follows: Nevada Consolidated, over 2500 men, \$40,756; Goldfield Consolidated, over 750 men, \$17,327; Tonopah Belmont, 400 men, \$9928; Mason Valley, \$4722; Pittsburg Silver Peak, \$3659; Round Mountain, \$2438; Nevada Hills, \$2610; Ophir Silver, \$1088; National Mines \$1428; Buckhorn Mines, \$3950; Yellow Pine, \$1288; and Prince Consolidated, \$1141. The balance was made up by railroads, lumber, power, and miscellaneous industries. A total of 1203 accidents were reported during the period. Of this num-

ber, 691 accidents incapacitated injured persons for less than two weeks, and 469 accidents for more than two weeks. Twenty-nine accidents resulting fatally were reported to May 31. The number of claims filed to May 31 reached 464, while cases involving 391 disabilities and 13 fatalities have been disposed of. Fifty-four claims have been rejected and eight claims withdrawn. During the life of the Commission the compensation paid totals \$37,125, and the compensation awarded and payable in monthly installments from the pension reserve fund reaches \$34,390. The expense of conducting the Commission totals \$23,372, and for furniture and fixtures \$3848 has been paid. The organization expenses were \$2084. In the asset column of the report the cash in the general fund is given as \$81,437; cash in the pension reserve fund, \$34,390; and cash in the insurance reserve fund, \$20,321. The total cash is given as \$136,148.

ESMERALDA COUNTY

Drifts have been driven 60 ft. north and south from the Goldfield Oro shaft at 810 ft. In the north end the quartz is more solid with better gold content, and in the south it is broken, but improving. Ore averaging \$100 per ton is being extracted from a winze below the Vernal 100-ft. level. W. S. Norris is superintendent. The 500-ft. level of the Silver Pick shows, at 150 ft. from the cross-cut, 12 in. of ore assaying \$58 gold, 2 oz. silver, and 5% copper; and 36 in. assaying \$22 gold, with similar silver and copper content. The Jumbo Extension is shipping about 90 tons of ore per day to the Goldfield Consolidated mill. The portion of the plant in use consists of the following, according to J. K. Turner, consulting engineer to the Jumbo Extension company: The ore is elevated from the main crusher to the ore-bins and thence falls through the gates to two 5-stamp batteries, an 8-mesh screen being used. All the product from the stamps passes over two sand roughing tables, the concentrate from these tables going to an iron tank outside the mill building. Tailing then passes to the Chilean mill, using a 24-mesh screen. The oversize goes to the finishing sand table, making a concentrate, which passes to the rectangular boxes in the drying-room, while the tailing is diverted to a discharge tank. The undersize from the Bunker Hill screen passes to two roughing slime tables. Concentrate goes to the rectangular boxes in the drying-room and the tailing to six finishing slime-tables on the main floor. The concentrate is carried to the rectangular boxes, and all tailing goes to a tank in the mill to be flushed out to the tailing pond. The deepest level of the mine, where drifts are being extended northeast and southwest from the raise above the 1017 ft. level, has continued to show 7 ft. of good mill ore. The higher-grade product, which contains silver and copper in addition to gold, is shipped to the Millers' sampler of the Western Ore Purchasing Co. Experiments are being conducted with a view to equipping the part of the mill that is treating Jumbo Extension ore with the flotation process.

The Goldfield Consolidated Mines Co. has come to an agreement with the Moore Filter Co. regarding royalty payable on the latter's process.

HUMBOLDT COUNTY

The Kromer-Hampton lease on the Nevada Packard mine is now producing about 30 tons of ore per month. A fourth shipment has been made which averages about \$60 per ton. The company is driving three adits to get under the rich shoots. In No. 6 and 7 levels of the National Mines Co. rich gold and silver ore has been opened. P. G. Harrison is in charge. Good headway is being made in the White Rock adit of the Charleston National company. In the Hatch lease of the Buckskin National company, the vein has been cut 30 ft. from the surface. Other lessees in the district are busy.

LYON COUNTY

A large number of bees have died in the Yerington valley of late, and some apiarists blame fume from the Mason Val-

ley smelter, but a number of causes have been suggested which would probably kill these insects. The plant treated 4942 tons of ore during the week ended June 17. An experimental leaching plant of 10-ton capacity is being erected at the smelter by E. R. Weidlein, of Pittsburgh.

The Casting Copper portion of the Nevada-Douglas property is now producing 120 tons of ore per day, averaging 6.75% copper. No. 5 raise is up 50 ft. from the 200-ft. level. The ore is all chalcopryite in schist formation, and assays 2.5% copper. Work at 300, 400, 600, and 700 ft. in the Ludwig is yielding fairly satisfactory results.

MINERAL COUNTY

At Rawhide, the Nevada New Mines Co. is employing 36 miners and 10 millmen, who are producing 900 tons of ore per month. A winze is down 35 ft. below the 500-ft. level, and the ore contains gold and ruby silver. The second bullion shipment for June amounted to 3100 oz. The Black Eagle company is milling 50 tons of ore per day. Lessees in the district are doing fairly well. The Goldfield Consolidated has acquired the Aurora property at a cost of over \$900,000.

NYE COUNTY

The Round Mountain company, R. H. Ernest, superintendent, is about to lay a pipe to sluice the hill of Round Mountain and other portions of its property. Water from Jett creek is to be used, and the pipe-line will be from 6 to 8 miles long. The Company's mine and mill are in continuous operation. Litigation between the Round Mountain Mining Co. and the Round Mountain Sphinx Mining Co. was concluded on June 16, the former Company absorbing the latter, while the capital of the Company will be increased from \$1,000,000 to \$1,500,000. James Robertson, of Tonopah, has been instrumental in making the agreement, ending five years' trouble in the courts. At Manhattan, installation of the surface equipment has taken longer than anticipated, due to the large amount of excavation necessary. The collar of the new shaft being on a hillside, the whole hill for 150 ft. in length and 50 ft. in width had to be leveled, necessitating the removal of over 2500 tons of rock. A shipment of five tons of concentrate caught by riffles below the tube-mill plates of the War Eagle mill, has been made. The product averages 20 oz. gold per ton. The local chalcidony rock is showing much greater efficiency than the imported Danish tube-mill pebbles at this mill.

Ten mines at Tonopah produced 49,008 tons of ore, worth \$82,130, in May. The West End treated 6250 tons at a profit of \$32,007. A pump with a capacity of 200 gal. per minute at a depth of 2000 ft. is being installed on No. 15 level of the Belmont mine.

George W. Abel, of Battle Mountain, has given the Denver Quartz Mill & Crusher Co. an order for a 25-ton Denver quartz mill, and the Denver Engineering Works an order for an Isbell concentrator.

STOREY COUNTY

Owing to the Mexican and Union companies, on the Comstock lode, refusing to help in operating the Union shaft and the joint Union-Sierra Nevada winze to prospect below 2500 ft., the Sierra Nevada has been temporarily shut down. The Ophir company is to stop work above 2500 ft. and ventilate this level; by this the Sierra Nevada will be able to operate through the C. & C. shaft. The winze below 2500 ft. is down 90 ft., and shows 8 ft. of \$7 ore. Connection was to be made at 2600 ft. and driving north done on the vein.

UTAH

BEAVER COUNTY

The Crott mine has been sold to G. W. Morgan and associates of Salt Lake City. A large vein, containing chiefly lead and silver, with some gold and zinc, has been opened for 3000 ft. along the strike, the deepest working being 100 ft. Copper ore has also been found in the south part of the property.

JUAB COUNTY

A jiggling plant is being used to treat old dumps at the Bullion Beck mine at Tintic. Two machines are treating 26 tons of ore per day, producing three tons of 40% lead and 18 to 22 oz. silver concentrate. The lessees have to pay a royalty of 25%. Jigs are also working at the Uncle Sam mine.

In the Dragon mine, at Silver City, is a large tonnage of iron ore averaging 50 to 60% metal, and it is stated that Jesse Knight will probably erect a blast-furnace in the district.

SUMMIT COUNTY

The Snake Creek tunnel was advanced 371 ft. in May, which distance is a record. The work is now in about 8000 ft., and a depth of 700 ft. The flow of water is 5200 gal. per minute. J. A. McIlwee & Co. are contractors.

A Holt-Dern mechanical roasting furnace will probably be installed in place of the present hand-rabbed furnaces at the Mines Operating Co.'s plant. A better roast, 10% better leaching, and a general saving of \$1 per ton is expected from the new furnace, based on results from a 10-ton machine which has been tried for several months.

The U. S. District Court has granted title to the Silver King Consolidated company to all ores vertically beneath the surface of the Electric Light, Cumberland, Ural, and Croesus claims at Park City. Shipments of products from Park City mines last week were as follows: Daly-Judge, 653; Silver King Coalition, 465; Silver King Consolidated, 310; and Daly West, 74; a total of 1502 tons.

WASHINGTON

STEVENS COUNTY

Trial runs have been made on the Copper King oil-burning smelter at Chewelah. The matte produced assayed 34% copper. The furnace was devised by J. J. Anderson, of Spokane. C. S. Batchelder is metallurgist.

CANADA

ALBERTA

An explosion in the Hillcrest colliery, near Frank, on the Crow's Nest line, is reported to have killed 200 men on June 18. Rescue cars and apparatus were rushed to the mine.

BRITISH COLUMBIA

Three blast-furnaces are now in commission at the Granby plant at Hidden Creek. There has been a shortage of silicious ore lately. A total of 1,250,000 lb. of copper has been produced since the new smelter started.

ONTARIO

An adjourned meeting of the Chambers-Ferland Mining Co. was held in Cobalt on June 10, and there was considerable discussion on the proposal to transfer the stock and assets for 115,000 £5 shares in the Aladdin Mining Co., which has few valuable assets. The meeting was adjourned to London, on July 1.

Eighty stamps are now working at the Dome mill, but the extra tube-mill is not quite ready. A continuous decantation plant is to be added to the McIntyre mill, and so increase the capacity from 150 to 300 tons per day. The last four weeks' report of the Hollinger company shows that mine development was satisfactory. The mill treated 15,200 tons of ore, including 831 from the Acme mine, averaging \$13.10 per ton, with 95.7% recovery. All costs amounted to \$4.219 per ton, and the gross profit was \$123,088. The net surplus is \$820,058.

YUKON

Thirty tons of rich silver ore, to be followed by 30 tons more, is being shipped from McWhorter's claim on Galena creek near Mayo. Forty-five claims have been recorded on Galena creek, and a total of about 60 in the district. Daily shipments of copper ore from the Pueblo mine to Tacoma are now about 240 tons.

Personal

CARR B. NEEL is in California.

F. B. VAN HORN is at Portland, Oregon.

J. A. HOLMES is at Fort Bayard, Arizona.

E. GYBSON SPILSBURY has returned from Belgium.

F. LYNWOOD GARRISON is on his way to Nome, Alaska.

MAN J. WELCH will be in Vantrent, California, for a few weeks.

BRADLEY STOUGHTON has returned from a brief trip to France and Spain.

C. F. RAND expects to reach New York, returning from Cuba, about July 1.

A. A. HASSAN has been examining the Big Injun property in Mineral county, Nevada.

H. C. MEEK has resigned as manager for the Dome Mines company of Porcupine, Ontario.

HORACE V. WINCHELL was in New York last week, returning from Europe, and has gone to Washington.

BERNARD MACDONALD has moved his office from 1005 Fair Oaks avenue, South Pasadena, to 533-4 I. W. Hellman building, Los Angeles.

F. YAMADA, mining engineer with the Tokio Copper Mining company of Tokio, Japan, was in Ontario recently and is visiting Western mines.

J. P. IDINGS, who has been lecturing in London, is visiting various European countries and will go to the Dutch East Indies for some months.

N. O. LAWTON, formerly superintendent of mines for the Miami Copper Co., is visiting some of the copper and iron mines of the Lake Superior district.

WILHELM ROSENFELT, of St. Petersburg, and A. SIMON, of London, are examining a copper property in the Altai mountains, Siberia. Later on the former will go to Turkestan.

T. E. MITCHELL, formerly assistant general superintendent for the Anaconda Copper Mining Co., has accepted the position of assistant general manager for the Burma Corporation, of Burma, East India.

E. S. MOORE passed through San Francisco this week on his way to the Australian meeting of the British Association for the Advancement of Science. He plans to spend next winter at the University of Berlin.

L. D. RICKETTS, general manager for the Greene Cananea Copper Co., THOMAS F. COLE, WILLIAM B. THOMPSON, and a number of others will shortly visit the property of the Consolidated Coppermines Co., at Ely, Nevada.

OSCAR LACHMUND, general manager for the British Columbia Copper Co., of Greenwood, British Columbia, was in Republic, Washington, last week, conferring with the Ben Hur Leasing Co. and other mining concerns in relation to ore shipments.

K. M. SIMPSON, formerly general manager for the Atlanta mines of Goldfield, is assistant general manager for the Goldfield Consolidated Mines Co., relieving J. W. HUTCHINSON, who is leaving to undergo treatment for injuries sustained last winter.

The U. S. Civil Service Commission calls attention to the fact that for the non-assembled open competitive examination for assistant mining engineer, scheduled for July 13, 1914, the maximum age limit will be 45 years on the date of the examination instead of 35 years as stated in the original announcement.

With the close of the present term at the Massachusetts Institute of Technology, ROBERT H. RICHARDS will be made professor emeritus, after forty-six years of teaching. In addition to the invaluable service he has given the Institute in the department of Mining Engineering and Metallurgy and as secretary of the Institute, he is well known in the mining profession as consulting engineer and expert in mining matters and for many technical books.

THE Montana section of the American Institute of Mining Engineers leaves Butte on August 9 for the Salt Lake City meeting. So far, 25 engineers have promised to attend from Montana.

CLARENCE L. CORY, professor of electrical engineering and dean of the college of mechanics of the University of California, was recently given the degree of Doctor of Engineering by Purdue University.

THE ninth International Congress of Applied Chemistry will be held at St. Petersburg, Russia, from August 8 to 14, 1915, according to the preliminary announcement, which contains all details of the meeting. The secretary is W. N. Ipatiew.

THE British Association for the Advancement of Science meets in Adelaide, South Australia, on August 8. A week at each state capital is planned, with excursions, one of which is to Broken Hill, New South Wales. About 400 members will attend from England.

THE University of California started its summer school with about 3000 students on June 22. There are only five permanent buildings on the Berkeley campus, and the Alumni Association of the University is to ask the people of California to vote bonds for \$1,800,000 to erect more substantial buildings to house students and valuable apparatus.

THE Mount Lyell School of Mines and Industries, affiliated with the University of Tasmania, is in full swing at Queens town. It is right at the centre of operations of the Mt. Lyell copper mines and smelters, and offers good opportunities for study in mining, treatment, power, and railways. Robert C. Sticht is president, and B. Whittington, registrar.

The Metal Markets

LOCAL METAL PRICES

San Francisco, June 25.

| | | |
|---------------------------|-----------------|----------------------|
| Antimony | 9 | — 9 $\frac{3}{4}$ c |
| Electrolytic copper | 15 | — 15 $\frac{1}{4}$ c |

Zinc dust, 100 kg. zinc-lined cases, 7 $\frac{1}{2}$ to 8c. per pound.

EASTER METAL MARKET

(By wire from New York.)

NEW YORK, June 25.—The past week's metal prices show little change from the previous week, copper being lower, and lead and spelter remaining as before. All markets are quiet and weak. Transactions on the Stock Exchange are very small, and copper shares are falling. The St. Louis lead and spelter markets are dull at 3.80 and 4.90c. respectively. Bar silver in London is quiet at 25 $\frac{3}{4}$ d. (51.75c.) per ounce.

SILVER

Below are given the average New York quotations in cents per ounce, of fine silver.

| June..... | 14.71 | | Dec..... | 14.25 | |

The cost of producing copper per pound in the United States, Canada, and Mexico last year showed a marked increase over that of 1912, according to Thompson, Towle & Co., of New York, who have computed this figure from the operating results of fifty of the largest producers in these countries. The properties in question include all the large porphyry mines of the West, the Michigan coppers, the mines of Butte, Bisbee, Globe, Clifton, and other large camps throughout the country, two British Columbia properties, and three of the largest Mexican mines, which yielded a total of 1,200,000,000 lb. of copper, about 85% of the total output of North America. The cost was 9.9c. per pound, against 9c. in 1912. Indications point to the current year's cost being lower than 1912.

Reports from 29 copper companies operating in the United States in 1912, and 30 companies in 1913, show the following totals, according to Hayden, Stone & Company:

| | 1913. | 1912. |
|---------------------------------------|---------------|---------------|
| Total production, pounds..... | 1,094,554,692 | 1,009,198,492 |
| Av. price received, cents per lb..... | 15.33 | 16.05 |
| Av. cost, cents per lb..... | 11.51 | 9.86 |
| Total profit..... | \$57,741,471 | \$82,420,445 |
| Average profit per share..... | \$3.90 | \$6.80 |

The output of these mines is nearly two-thirds of the entire American production. In spite of the Lake Superior strike, which greatly hampered the mines in that district, the 1912

and 1912 figures are practically the same, the loss from the Lake mines being made up chiefly by the gain from the porphyries. The higher cost of production and lower price obtained for the metal in 1913 made a considerable difference in the net profits, which were \$25,000,000, or nearly \$3 per share, smaller in 1913 than in the preceding period. Nevertheless, that the properties which turn out two-thirds of the total American output of copper can, under such unfavorable circumstances as prevailed during the greater part of the past year, earn approximately \$4 per share on the capital stock outstanding, is good evidence of the profitability of good mining investments. Especially is this true when we consider the comparatively small amount of cash paid in, usually not over \$25 per share, and frequently nearer \$10 per share.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

| Week ending | | June 11..... | 38.50 |

TIN

New York prices control in the American market for tin, since the metal is almost entirely imported. San Francisco quotations average about 5c. per lb. higher. Below are given average monthly New York quotations, in cents per pound:

| | 1913. | 1914. | | 1913. | 1914. |
|-----------|-------|-------|-----------|-------|-------|
| Jan..... | 50.45 | 37.85 | July..... | 40.70 | |
| Feb..... | 49.07 | 39.76 | Aug..... | 41.75 | |
| Mch..... | 46.95 | 38.10 | Sept..... | 42.45 | |
| Apr..... | 49.00 | 36.10 | Oct..... | 40.61 | |
| May..... | 49.10 | 33.29 | Nov..... | 39.77 | |
| June..... | 45.10 | | Dec..... | 37.57 | |

Gold and silver received at the San Francisco mint during May amounted to 170,543 and 46,597 fine oz., respectively, with a total value of \$3,565,746. Coinage executed in the period was worth \$2,123,500. Coin, bullion, etc., on hand at the close of business was \$241,278,331.

Coal-mine fatalities in the United States in April totaled 238.

Gold Production in New Zealand

During May, the Hauraki peninsula, which contains all of the gold-silver mines of the North Island of the Dominion, produced the following returns:

| Mine and District. | Tons. | Value. | Dividend. |
|--------------------------------------|--------|---------|-----------|
| Mt. Welcome, Coromandel..... | 4 | \$ 520 | |
| New Waitaia, Coromandel..... | 124 | 6,500 | |
| Talisman, Ohinemuri..... | 3,950 | 105,000 | |
| Waihi, Ohinemuri..... | 14,602 | 120,000 | \$115,000 |
| Waihi Grand Junction, Ohinemuri..... | 8,610 | 88,000 | |
| Waihi-Paeroa, Ohinemuri..... | 12,400 | 19,500 | |
| New Sylvia Thames..... | 860 | 4,900 | |
| Occidental, Thames..... | 0.05 | 1,400 | |
| Watchman, Thames..... | 868 | 4,400 | |

The Waihi-Paeroa tonnage represents tailing recovered from the Ohinemuri river. During 1913 the Waihi company treated 184,768 tons of ore, yielding gold and silver bullion worth \$1,530,000, of which \$670,000 was profit and \$476,070 was paid in dividends. Ore reserves total 764,732 tons. The Waihi Grand Junction treated 98,383 tons in 1913, yielding \$870,000. The profit was \$190,000, and \$92,000 was paid in dividends. Gas is still troublesome in the main cross-cut, at 1000 ft., which is to drain and prospect the deeper areas of the Thames field.

GOLD PRODUCTION of the Kolar, India, group of mines in May was as follows:

| Mine. | Tons. | Ounces. |
|--------------------|--------|---------|
| Balaghat..... | 3,200 | 1,412 |
| Champion Reef..... | 18,031 | 11,444 |
| Mysore..... | 25,155 | 19,540 |
| Nundydroog..... | 7,500 | 6,638 |
| Ooregum..... | 12,914 | 7,606 |

OPERATIONS of the Lenskoie mine, controlled by the Lena Goldfields company, Siberia, from October 1, 1913, to April 30, 1914, were as follows: Men employed, 7574; gravel mined, 487,161 cu. yd.; gravel washed, 71,274 cu. yd.; and average gold content, \$6.90 per yard. The washing season is now in full swing.

MANGANESE-ORE PRODUCTION of the Caucasus districts of Russia in 1913 totaled 1,051,559 tons. Imports into America and Europe from all sources were 2,172,684 tons.

METAL PRODUCTION of the Aramayo Francke mines, Bolivia in May was as follows: tin, 290 tons; copper matte, 5 tons; and silver ore, 58 tons.

GOLD PRODUCTION of the Mt. Boppy mine, New South Wales, in May was valued at \$48,000, from the treatment of 6069 tons of ore.

COAL OUTPUT of the Chinese Engineering & Mining Co. during the last week of May was 39,000 tons. Sales totaled 43,000 tons.

GOLD OUTPUT of the Kolar goldfield, and two outside mines in India, was 49,495 oz. in May, against 48,860 oz. in May of 1913.

GOLD OUTPUT of the St. John del Rey mine, Brazil, in May was \$177,600, from 16,000 tons of ore.

Company Reports

INDIANA MINING COMPANY

This is a Lake copper company in which the United States Smelting Refining & Mining Co. has a substantial interest. The shaft has been sunk to a depth of 1415 ft., and prospecting is in progress. The following are details of cost: Shaft-sinking, mining 211 ft., \$4454; timbering, \$3560; and power, \$2792, a total of \$10,806, less \$206 for machinery sold, equals \$10,600 or \$50.24 per foot. Cutting station at 1400 ft., \$432; driving and cross-cutting 270 ft. at \$17.52 per foot, \$4737; and diamond-drilling, \$4190. The shaft is cylindrical, 17 ft. outer diameter, 8 by 12 ft. inner, lined with steel concrete.

FRANKLIN MINING COMPANY

This is a Lake copper company in which the United States Smelting, Refining & Mining Co. has a substantial interest. About 1,000,000 lb. copper was produced in 1913, chiefly from prospecting work, which amounted to 2000 ft. during 1913 up to July, when work was stopped by the strike. The following statement of costs and expenditures during 1913 is of interest: Mining expense—Sinking 117 ft. at \$10.057 per foot, \$1177; raising 397 ft. at \$5.86 per foot, \$2327; driving 1299 ft. at \$5.181 per foot, \$6730; cross-cutting 134 ft. at \$4.903 per foot, \$657; stoping 8897.9 fathoms at \$6.1516 per fathom, \$57,985; compressor and drills, \$20,076; and labor and other expenses, \$41,779; also hoisting expense, 127,033 tons, \$18,645; rock-house expense, \$3128; transportation, \$12,806; surface and incidental expense, \$15,520; stamp-mill expense, \$38,648; prospecting, \$4384; and taxes for 1913, \$11,202; a total of \$235,064.

RHODESIA GOLD MINING & INVESTMENT CO., LTD.

The capital of this Company is £300,000 in £1 shares, and it has share interests in the following Rhodesian companies: Lonely Reef Gold Mining Co., 34,296 out of 271,007 £1 shares; Sabi Gold Mining Co., 49,896 out of 50,000 £1 shares; Cam & Motor Gold Mining Co., 43,000 out of 517,500 £1 shares; Hay Gold Mining Co., 13,471 out of 140,700 £1 shares; United Rhodesia Goldfields, 4500 7s. 6d. shares; and Rhodesia Native Labor Bureau, £500 5s. debentures. The shares costing £99,177 had a market value of £135,210 at the end of 1913. The Company also has mining interests in the Bernheim mines, Pretty Polly mine, and Felixburg claims.

Ore reserves in the Lonely Reef mine are 172,557 tons assaying \$17.14 per ton. The mill in 1913 treated 58,903 tons yielding £218,520, of which £126,392 was profit. A dividend of 30% was paid. Francis Drake is general manager of this property. The Cam & Motor mill started work in January, 1914, and alterations have since been made to permit of the estimated capacity being attained. Ore reserves are estimated at 1,016,240 tons worth £2,262,150. Reserves in the Bernheim mines are 25,000 tons of \$8.75 ore. A separate company was formed to work the Sabi mine, and development in the Bernheim group is sufficiently advanced for a similar proceeding. Ore developed in the Sabi property amounts to 49,000 tons of \$10.36, and 3300 tons of \$8.85 ore. A few thousand tons of ore has been opened in the Felixburg claims. At the Pretty Polly, 1292 tons was milled and some sand treated, the total averaging \$4.828 per ton.

The year's profit was £6954, and £25,173 was brought forward from 1912. Receipts totaled £11,239.

PACIFIC GAS & ELECTRIC COMPANY

This is primarily an industrial concern operating in California, and is one of the four or five largest similar corporations in the United States, and the significance of its report to readers of a mining journal is on account of the im-

portance of the Company as a supplier of electric power, also water, for mines, mills, and dredges in many counties. This power is supplied at about an average of 1 cent per kilowatt-hour. Out of a total revenue from sales of electricity during the past year, amounting to \$8,230,782, the mining industry contributed \$557,462, or about 7%. The Company's operations may be summarized as follows:

| | |
|--|---------------|
| Number of consumers of gas, electricity, water, and steam | 349,417 |
| Gas sold, cubic feet | 7,430,000,000 |
| Revenue from gas | \$6,547,595 |
| Capacity of all electric generating plants, water and steam, horse-power | 233,928 |
| Revenue from electricity | \$8,230,782 |
| Water pumped, gallons | 1,510,417,976 |
| Revenue from water, etc. | \$ 851,047 |
| Revenue from Sacramento street railway..... | 572,913 |
| Total revenue for 1913 (\$14,744,651 in 1912)..... | 16,202,337 |
| Maintenance, operation, distribution, and administration expenses | 9,331,207 |
| Interest on notes, debt, bonds, etc. | 4,148,086 |
| Net income | 2,723,044 |
| Dividends on preferred (6%) and common (1¼%) stock | 998,848 |
| Salaries and wages paid..... | \$6,955,817 |
| Employees | 6,778 |

GOLDEN HORSE-SHOE ESTATES COMPANY, LTD.

Financial results of this Kalgoorlie company were discussed in the 'Special Correspondence' pages of this journal of June 20. During 1913 the mills, sand, slime, and concentrate plants crushed 280,512 long tons of ore at a cost of \$1.17 per ton; leached 91,935 tons of sand at a cost of 70c. per ton; filter-pressed 165,591 tons of slime at a cost of \$1.49 per ton, in-

TWO 500-KW. A. E. G. TURBO-GENERATORS AT THE HORSE-SHOE. LOW-PRESSURE CYLINDER OF INGERSOLL-RAND COMPRESSOR SHOWING ON UPPER LEFT.

cluding settling, agitating, cyaniding, and filtering; and roasted and cyanided 22,986 tons of concentrate at a cost of \$2.75 per ton. There was also treated 16,930 tons of old residue yielding 2259 oz. fine gold. The total yield was 97,423 oz. gold, the recovery being 83.2%, and total cost \$5.40 per ton. The total revenue in 1913 was £415,571, out of which there was a net balance of £42,698. From 1912 the sum of £35,603 was brought forward, making a total of £78,300. Debenture interest absorbed £12,500, and dividend No. 36, £60,000, leaving £5800 for the current year. The plant, which cost £571,829, stands in the Company's books at £45,000. Stores worth £22,745 are on hand at the mine.

In his report the general manager, J. W. Sutherland, states that development totaled 9485 ft., including 634 ft. of shaft-

sinking, at a cost of \$22.65 per foot. Of this, 3308 ft. was in barren rock, the balance in ore. The total to date is 137,104 ft., including 3961 ft. of diamond-drilling. Development in this mine has attracted considerable attention of recent years, especially on No. 4 lode, near the Great Boulder boundary. A geological report was made by C. O. G. Larcombe, of the local school of mines. The main shaft was sunk to 2836 ft., and No. 2 to 1879 ft. Both shafts are still being deepened. No. 2 lode produced 121,076 tons of \$8.17 ore, and continues to open well south on the lower levels. No. 3 lode yielded 150,897 tons of \$8.19 ore, and is also showing well at the south. A fault disturbed it at 2630 ft. No. 4 lode produced 8539 tons of \$19.43 ore. This lode came into Horse-Shoe ground from the Great Boulder at about 2550 ft. depth, and is still dipping farther in. It was cut by the east cross-cut from the main shaft at 2780 ft. On this level a new shoot of ore was opened, being 4 ft. wide, worth \$10 per ton. Ore reserves are estimated as 715,496 tons averaging \$8.15 per ton.

The output of this great mine to date is 2,992,615 long tons, yielding 2,128,210 oz. fine gold, and £3,135,000 in dividends.

SEOUL MINING COMPANY

Monthly yields of this Company, operating in Whang Hai province, Korea, are published regularly in this journal, and the report under review covers the year ended December 31, 1913.

The general manager, A. H. Collbran, reported as follows: Development in the Suan mine totaled 5505 ft., making 28,563 ft. to date. Most of the stoping was done by machines, a larger compressor having been installed. Ore reserves in the three orebodies, and including broken ore in stopes, amount to 315,538 tons averaging gold, \$9.08; copper, 1.04%; and bismuth, 1.7 lb. per ton, an average gross value of \$13.22 per ton. In the Tul Mi Chung mine, of which E. W. Mills is superintendent, the sum of \$129,191 has been spent in development to date. In 1913, work amounted to 7179 ft., and 10,214 ft. to date. Ore reserves total 276,880 tons averaging gold, \$6.08; silver, 0.8 oz.; and copper, 1.37%, worth \$10.63 per ton. A complete sorting system was started on July 1, and to the end of the year 1480 tons of waste was discarded at a cost of 3.8c. per ton. The gold content of the ore was thereby increased by 34c. per ton.

Owing to a shortage of water the 40-stamp mill worked 327.6 days, and crushed 71,535 tons of ore, an average of 5.46 tons per stamp day. The ore averaged \$9.51 gold and 1.019% copper, also some bismuth. Gold recovered by amalgamation was 76.79%. Concentrate production was as follows:

| | Regular. | Canvas. | Black. |
|-------------------------|----------|----------|----------|
| Tons | 555 | 65 | 149 |
| Gold, per ton | \$68.75 | \$111.99 | \$140.09 |
| Copper, per cent | 18.34 | 16.36 | 24.31 |
| Bismuth, per cent | 1.71 | 3.72 | 3.36 |

The total gold recovery was 86.54%, and copper 20.50%. Value of all products extracted was \$671,537. Operating costs were \$4.13, and profits \$5.26 per ton. Dividends equal to 50% on the capital of \$500,000 were paid. The sum of \$55,411 was carried forward to 1914.

Tests were made on ore from the Tul Mi Chung mine by W. G. Perkins, and 90% extraction can be made by crushing, amalgamation and concentration of the gold-silver-copper ore. A mill with an initial capacity of 300 tons per day is to be erected. On account of the diminishing supply and increasing cost of firewood, an electric power-plant of two 1000-kw. steam turbo-generators is being constructed at Pyeng Yang, 47 miles from Holkol and Tul Mi Chung. H. Maki is engineer of this department, and he hopes to finish the plant by September, 1914. Motors are to be installed in the Sockaire mill.

The general report contains a good deal of interesting information on prospecting other areas, roads, telephones, rainfall (23.35 in.), hospital treatment, and new equipment. There were 5486 natives employed by the Company.

CALUMET & HECLA MINING COMPANY

Like all the other Michigan copper companies in 1913, this one suffered considerably through the miners' strike which started last July. Results of the past three years show the decreased output and profits, as follows:

| Development on— | 1913. | 1912. | 1911. |
|-----------------------------|--------------|---------------|--------------|
| Conglomerate lode, ft.. | 6,101 | 11,185 | 9,360 |
| Osceola lode, ft..... | 7,533 | 18,504 | 19,889 |
| Kearsarge lode, ft..... | 428 | 2,140 | 2,008 |
| 'Rock' stamped from all | | | |
| lodes, tons | 2,035,625 | 2,806,610 | 2,909,972 |
| Old tailing treated, tons.. | 388,164 | 481,320 | 477,794 |
| Refined copper from all | | | |
| sources, lb. | 45,016,890 | 67,856,429 | 74,130,077 |
| Copper per ton of rock, lb. | 22.11 | 24.18 | 25.47 |
| Copper per ton of tailing | | | |
| treated, lb. | 11.92 | 12.86 | 12.66 |
| Price received for copper, | | | |
| cents per pound..... | 15.77 | 16.65 | 12.82 |
| Total cost, cents per pound | 14.25 | 9.86 | 8.52 |
| Dividends from subsidiary | | | |
| companies | \$ 915,439 | \$ 892,775 | \$ 295,225 |
| Dividends paid in 1913... | 3,200,000 | 4,200,000 | 2,400,000 |
| Dividends paid to date... | | \$123,250,000 | |
| Cash at mine, New York, | | | |
| and Boston at end of re- | | | |
| spective years | \$ 3,840,162 | \$ 6,818,093 | \$ 7,245,437 |
| Supplies on hand..... | 1,772,324 | 1,329,810 | 1,189,690 |
| Sinking fund | 446,466 | 1,166,999 | 1,446,116 |
| Total assets | 7,280,229 | 11,560,426 | 11,720,449 |
| Total liabilities | 726,265 | 844,012 | 457,342 |
| Profit and loss surplus... | 6,553,964 | 10,716,414 | 11,263,107 |

The Company holds a large interest, controlling in some, in the following companies: Ahmeek, Allouez, Centennial, Cliff, Gratiot, Isle Royale, La Salle, Laurium, Osceola, Seneca, Superior, Tamarack, and White Pine.

In the Conglomerate lode 20 drills are at work removing shaft pillars and cleaning-up arches and backs of old stopes.

LINE OF SHAFTS AT HOUGHTON, MICHIGAN.

A special one-man drill has been devised to meet conditions of working this lode, and it is gradually being introduced.

At the new regrinding mill, half of the machinery is erected, and the dredge to recover old tailing from Torch lake should be finished this summer. With a daily capacity of 3000 tons, and recovery of 5 lb. of copper per ton at a cost of 6c. per ton, the profit in 30 years will be \$10,000,000. With leaching applied to most of the residue from this plant, another \$10,000,000 profit will be made. It will also be applicable to conglomerate rock unmined, and Tamarack sand, and White Pine rock. A second mechanical furnace is finished at the smelter, and part of the new electrolytic refining plant is in commission. Expenditure of the aid fund last year was \$51,592.

Recent Publications

ANALES DE LA DIRECCION FOMENTO, 1913. No. 1 to 6. Monthly journals of about 90 pages. Lima, Peru.

ROCKY MOUNTAIN MINE TIMBERS. By Norman de W. Betts. Professional paper from the Forest Service, Bulletin 77. P. 34. Illustrated. U. S. Department of Agriculture, Washington, 1914. This is an interesting discussion for mining men.

GOVERNMENT OWNERSHIP OF RAILWAYS. List of publications pertaining to Bulletin 62. P. 74. Index of authors. Bureau of Railway Economics, Washington, 1914. The live discussion of this subject of late makes this list of abstracts of publications especially timely.

TESTS OF BOND BETWEEN CONCRETE AND STEEL. By Duff A. Abrams. Bulletin 71. P. 238. Illustrated. University of Illinois Engineering Experiment Station, Urbana, 1914. In these days of the great use of reinforced concrete structures, this publication is of special value to constructing engineers.

THE COMMERCIAL ASPECT OF ELECTRIC ZINC-LEAD SMELTING. By Woolsey McAlpine Johnson. Paper presented at annual meeting of the Canadian Mining Institute, Montreal, May 4-6, 1914. P. 21. Increasing attention is being directed to this form of reduction of zinc-lead ores, which has been described in this journal recently.

TWELFTH ANNUAL REPORT OF THE BUREAU OF SCIENCE, Philippine Islands. By Alvin J. Cox. P. 131. Ill., index. Manila, 1913. The Bureau of Science conducts investigations into a great variety of subjects, coming under its jurisdiction in this tropical area, such as pneumonic plague, cholera, tobacco beetles, silk culture, stone industry, plant life, hat making, fruit, cocoanuts, sugar growing, portland cement, pottery, brick, coal, oil prospecting, mineral veins of the Baguio district, and gold nuggets from the Paracale placer deposit.

COAL IN ALASKA. Report on its possible use in United States Navy. A letter from the Secretary of the Navy dealing with surveys, and experimental tests on the coal on warships. P. 123. Maps and 12 plates. Washington, 1914. The conclusion is arrived at, that the failure on test of the excellent Bering River sample at the Engineering Experiment Station from severe and unusual clinkering, a sample better in all respects than the Pocahontas used in comparative test, obliges the department to regard and so report the Bering River field to be unavailable as a source of coal for the Navy, until extensive general development definitely locates coal not possessing the serious objection found in the sample tested by the department.

United States Geological Survey publications, Washington, 1914:

Advance chapters from 'Mineral Resources of the United States, 1913':

PRODUCTION OF MINERAL PAINTS. By James M. Hill. P. 24.

PRODUCTION OF SLATE. By A. T. Coons. P. 16.

SULPHUR, PYRITE, AND SULPHURIC ACID. By W. C. Phalen. P. 29.

RESULTS OF TRIANGULATION AND PRIMARY TRAVERSE IN OHIO, 1898 to 1911 inclusive. R. B. Marshall, chief geographer. Bulletin 552. P. 232. Map.

EROSION AND SEDIMENTATION IN CHESAPEAKE BAY AROUND THE MOUTH OF CHOPTANK RIVER. By J. Fred Hunter. Professional paper 90-B, shorter contributions to *General Geology*, 1914-B. P. 15. Maps.

Recent Patents

1,097,708—Machine for washing precipitates. Harry E. Elson, Masontown, Pennsylvania.

A filter funnel holding stand, means for rotating the stand, and means for supplying a wash liquid to a filter supported in the stand.

1,098,443—Process for separating copper from nickel and cobalt. Victor Hybinette, Fredericktown, Missouri.

The process of separating copper from nickel and cobalt in sulphide ores and products from concentration, consisting in roasting the material, thereafter subjecting it to magnetic separation, making concentrate; when necessary partly removing the sulphur from the concentrate by roasting said matte, leaching said roasted matte with diluted sulphuric acid, thereby obtaining a solution containing principally copper.

1,098,611—Device for treating smelter fume. Olof V. Blom, Fresno, California.

A conduit for use in treating smelter fume, the same comprising an inclined conduit arranged in steps, a receptacle opening into said conduit just below the junction of adjacent steps and disposed at substantially right angles to said conduit, whereby the bottom of each receptacle inclines toward its lower corner, a door in the lower corner of each receptacle, another receptacle disposed below each of said first-named receptacles, and a pipe leading from the upper side of one end of each of said first-named receptacles to the corresponding receptacle below the same, as described.

1,097,113—Concentrator. Arthur L. Wilfley, Denver, Colorado.

The combination of a tiltable concentrating table closed at its rear side and open at its opposite side for discharge purposes and means for automatically tilting the table for two positions of successively greater inclination in a forward direction for the purpose of discharging the gangue and concentrate, respectively, and in the order named, and then reversing the table's movement, and finally tilting it rearwardly to permit the accumulation thereon of a charge of pulp and means for supplying pulp to the table during the period of rearward inclination, substantially as described.

1,097,139—Concentrator. John Malcolm Nicol, Mill Valley, California.

An apparatus for separating materials of different specific gravity, comprising a substantially smooth flat belt transversely inclined and having longitudinal riffles, each of said riffles having a flat smooth plane inclined side joining the substantially flat plane of the belt at an obtuse angle and adapted to serve as a dam at the feed portion, and means beyond the feed portion and toward the concentrate discharge end for gradually reducing the inclination of said riffle planes to a horizontal in advance of the concentrate discharge end.

1,097,592—Sintering machines. Eugene Hiram Laws, Salida, Colorado, assignor to the Ohio & Colorado Smelting & Refining Co., Denver, Colorado, a corporation of Colorado.

The combination with a traveling grate made up of articulated ore-bearing pallets having air passages therethrough and provided with rollers on both sides, and a suction box having its mouth opening up to the pallets and terminating in dead plates at both ends, of vertically adjustable means for supporting the pallets on their rollers with their bottoms in close proximity to but out of wearing engagement with the edges of the suction box and with the dead plates during their passage thereover, substantially as described.

Industrial Progress

The CHICAGO PNEUMATIC TOOL Co. has issued Bulletin 185, illustrating the varied uses of the portable gasoline-driven compressor manufactured by that firm.

THE LUNKENHEIMER Co. is distributing an attractive little booklet descriptive of the 'Renewo' valve made by that firm. In this valve all parts are renewable, particularly the seat and disc.

AMERICAN CONCENTRATOR Co., of Springfield, Ohio, in 'Bulletin No. 2' describes the equipment of its coal and ore testing laboratory. Special attention is given the testing of iron ores and design of concentration plants.

SULLIVAN MACHINERY Co. announces appointment of J. C. West as general sales engineer, with headquarters at Chicago. Mr. West will be succeeded at San Francisco by Ray P. McGrath, heretofore stationed at Boston.

The DENVER QUARTZ MILL & CRUSHER Co. published recently a leaflet contrasting by means of pictures the first mill built by the Company in 1908 with the 100-ton mills now being built. The 1908 mill had seven 300-lb. rolls and a total weight of 4500 lb. The modern mill has four 3200-lb. rolls and a total weight of 32,000 pounds.

THE JOSHUA HENDY IRON WORKS' Bulletin 124 is descriptive of the Hendy quartz stamp mills, with single and triple discharge mortars. Over 1000 of these unit mills have been sold since 1895. The small size and large capacity suits them especially to pioneer conditions, and from Nome to South America they are found on the skirmish line.

H. S. RENSHAW Co., LTD., 207-208 Metropolitan Bank Bdg., New Orleans, Louisiana, asks us to say that owing to accidental destruction of current files, the sending of complete catalogs by manufacturers of mining machinery and supply houses will be appreciated. This firm is purchasing agency for the Canadian Agency, Ltd., and other large operators in Latin America.

The Duluth office of the H. W. Johns-Manville Co. has moved to larger quarters at No. 327 West First street, in order to take care of its increased business. The new office is on the ground floor, with windows for the display of J-M asbestos roofing, pipe coverings, packings, sanitary specialties, auto accessories and other products of this Company's well known and varied lines.

H. N. ELMER, North American agent for Siebe, Gorman & Co., Ltd., announces that the MINE SAFETY APPLIANCE Co., of Pittsburgh, has been appointed agents for 'Proto' mine-rescue apparatus in Eastern territory. The MINE SAFETY APPLIANCE Co. is a new concern formed by G. H. Deike and J. T. Ryan, engineers, who have resigned from service with the U. S. Bureau of Mines to enter commercial life.

A number of the employees of the WESTINGHOUSE ELECTRIC & MANUFACTURING Co. and the WESTINGHOUSE MACHINE Co. went on a strike during the first week of June, because the management refused to recognize the demands of the newly formed labor union, the Allegheny Congenial Industrial Union, and as a result the works of these Companies at East Pittsburgh are partly shut down. The management of the Company does not believe that the trouble will be of long duration.

The LUFKIN RULE Co. announces the issuing of a new catalog, No. 9. Its 110 pages are devoted exclusively to measuring tapes and rules, and it is unusually complete. Special attention is invited to the fact that in addition to measuring tapes and steel rules, which lines the Company has manufactured for the last 25 years, it now has ready for the market

a complete line of folding boxwood and flexible spring joint wood rules. Requests for copies of the new catalog will receive prompt attention.

THE TRAYLOR ENGINEERING & MANUFACTURING Co. announces that arrangements have been completed with Charles A. Jacobson for the manufacture and sale of the 'Jacobson' gas-engines. Mr. Jacobson was the pioneer in the introduction of large gas-engines in the United States and has plants in operation in every part of the country. The 'Jacobson' gas-engine is of the scavenging type, and can be used on natural, producer, and illuminating gases of all kinds and characters. The starting device is the 'Jacobson' air starter. The engines are built in all sizes with single and multiple cylinders and particularly adapted for direct connecting to alternators running in parallel.

MESTA MACHINE Co., of Pittsburgh, Pennsylvania, has for distribution Bulletin N, which is descriptive of the air-compressors and vacuum pumps manufactured by this Company. A distinguishing feature of the Mesta compressor is the automatic plate valve, which it is claimed, makes possible the economic use of much higher piston or rotative speed, which speed is limited only by the speed of the driving engine, or by general wear and tear on the compressor, if the latter be driven by electric power. Some of the advantages claimed for this type of valve, which is known as the Iversen patent, are the simplicity of the air end, high volumetric and mechanical efficiency, lack of wear on valve and seats, no lubrication of valves required, noiseless at high speed, and no adjustment valves necessary.

THE BUSCH-SULZER BROS.-DIESEL ENGINE Co. has closed a contract with the Lake Torpedo Boat Co. for six 600-hp., reversible, ten-cycle, marine Diesel engines to be placed on three new twin-screw submarine torpedo-boats for the U. S. government. These engines, which are being built at St. Louis, will be similar to two sold to the Lake company some time ago for the same purpose. The control is so arranged that a single operator has complete control over both engines. Each is provided with two separate scavenging pumps arranged in line with the working cylinders, also two 3-stage injection air-pumps; all are operated from the crank-shaft, and each engine has its own water and oil circulating pumps. Excepting air-storage bottles, these engines are complete units with all parts integral. These marine engines are totally different, in every way, from the non-reversible 2 and 4-cycle massive engines which the Company is building for stationary purposes, or from the light-weight marine type Diesel-generator sets supplied to the Argentine for the first-class warships *Rivadavia* and *Moreno* which were recently completed in this country.

THE INGERSOLL-RAND Co. has ready for distribution a limited number of books, 'Photographs in Color of the Panama Canal.' This book illustrates the dams and locks in natural color, and in addition is supplemented with a very concise article on 'What the Canal Will Accomplish' by Emory R. Johnson. Copy will be sent free on request. 'Form 4020,' also issued by the Ingersoll-Rand Co., is a 32-page catalog on Leyner-Ingersoll water drills. Among the several unique features of construction may be mentioned the 'Hand Hammer Blow,' the 'Water Feature,' the 'Oiling System,' the 'Butterfly Valve,' 'Sergeant Rotation,' 'Irco Metal,' etc. 'Little David Riveting Hammers,' Form 8011; and 'Rivet Set Retainer for Little David Hammers,' Form 8011-1, are the subjects of two other bulletins just issued. All those interested in 'safety first' as applied to the operation of pneumatic riveting hammers will be interested in these booklets. All 'Little David' riveting hammers can be furnished with a rivet set retainer, which meets the requirements of the safety laws being drafted by the various states. These bulletins are illustrated to show application of the tools, and also give sectional views to show the details.
